Executive councils are included among the bodies on whom no development charge under the provisions of the Town and Country Planning Act, 1947, will be levied. They will make no claim against the £300,000,000 provided as compensation for loss of development rights in Part VI of that Act. Any claim which has already been submitted to the Central Land Board should be withdrawn.

"MYANESIN" IN THE TREATMENT OF TETANUS

BY

M. H. ARMSTRONG DAVISON, M.D., D.A.

A. B. WARD, M.B., B.S.

AND

E. A. PASK, M.A., M.D., D.A.

(From the Department of Anaesthesia, Royal Victoria Infirmary, Newcastle-upon-Tyne)

The use of myanesin in tetanus was reported by Belfrag (1947) in two cases. Two further cases are described below, and these may be of interest in that they throw some light on the production of haemoglobinuria, a complication which has been reported in about twenty cases after myanesin.

Pugh and Enderby (1947) observed three cases of haemoglobinuria. The first urine passed after injection was discoloured, but no haemoglobinuria was found after two days. A death from renal anoxia after use of myanesin was reported by Hewer and Woolmer (1947), but it was pointed out by Mallinson (1948) that there were reasons for considering that myanesin was not the cause of death. A number of other cases have been described, but all were symptomless and cleared up spontaneously.

Hunter and Waterfall (1948) found myanesin useful in the control of epileptiform fits, a finding which is slightly at variance with those of Berger and Bradley (1946) that myanesin in non-paralysing doses had a powerful effect on strychnine-poisoning by depressing the reflex excitability of the spinal cord, but that the relative lack of antagonism to leptazol showed the midbrain to be influenced only when large doses were given. They thought that as myanesin does not affect consciousness or cause prenarcoctic excitement it had no action on the cerebral cortex.

Davison (1948) suggested that the action was on the internuncial neurones in the spinal cord, because of the production of relaxation, apparently by reduction in muscle tone, without marked interference with respiration or voluntary movements. Berger and Bradley (1946) found that paralysis in animals was of longer duration in the hind half than in the anterior portion.

Case 1

A farm labourer aged 40 suffering from tetanus was admitted to the Royal Victoria Infirmary on June 8, 1948. He had received a small splinter wound on the palm of the hand nine days before symptoms developed. A curious but probably entirely irrelevant fact was that he stated that his brother had died in childhood of "lockjaw." There was severe generalized muscular hypertonia, affecting particularly the gluteal muscles, abdominal muscles, and the muscles of respiration and there was also very marked neck rigidity. The characteristic tetanic spasms occurred only half a dozen times. He was treated with sedatives, mainly intramuscular paraldehyde, but after about a fortnight his tolerance to these drugs had increased so much that they were practically valueless. Soon after admission, when the muscle tonus was very pronounced and was interfering greatly with respiration, he was given *d*-tubocurarine chloride ("tubarine") 7½ mg. intravenously and an equal dose intramuscularly. This abolished his muscle tonus but also paralysed all muscles of respiration. Artificial respiration was carried out with the Oxford insufflator for more than an hour. When subsequently he developed spasms these were treated with *d*-tubocurarine chloride, and artificial respiration was always necessary if sufficient was given to control the muscular movements. This was difficult, because the patient was edentulous and it was hard to secure effective inflation. On the fifth day after admission he developed a

cough, and two days later he had signs of patchy consolidation at both lung bases. These persisted for nine days. At a subsequent date myanesin in doses of 5 to 10 ml. was administered intravenously, with beneficial results. The abdominal and intercostal muscular rigidity disappeared for periods up to an hour after each injection, and respiration became much easier, but at no time did myanesin relax the rigidity of the posterior neck muscles or have much action upon the glutei. A total of 58 ml. of myanesin was given in 60 hours; haemoglobinuria was not seen.

In addition to the above treatment the patient was fed through a Ryle's tube, received penicillin to minimize the danger of respiratory infection, and was given massive doses of A.T.S. He recovered.

Case 2

A more serious case was admitted to the Royal Victoria Infirmary on June 18, 1948. The beneficial results obtained with myanesin in the previous case seemed to warrant its use, and in addition it was hoped to avert pulmonary complications by avoiding marked respiratory depression.

The patient, a man aged 58, had had an arthrodesis of the left knee performed four weeks previously, and was admitted about twenty-four hours after symptoms of tetanus made their appearance, the first being inability to insert his false teeth. An attempt to pass a nasal catheter failed on account of spasm of the pharyngeal muscles. He was given 200,000 units of A.T.S. Eight hours after admission the muscle spasms were recurring every two or three minutes; myanesin, 10 ml. intravenously, was given with considerable benefit, but a further 5 ml. became necessary thirty-five minutes later. A Ryle's tube was now passed with ease and glucose was given through it at hourly intervals. Penicillin was also given intramuscularly. An intravenous drip was set up containing 5% glucose in N/5 saline, to which myanesin was added in varying amounts as seemed to be dictated by the condition. It was found that the addition of more than 70 ml. of myanesin in 540 ml. of glucose-saline produced a white flocculent precipitate.

During 26½ hours the patient received 265 ml. of myanesin. The muscle spasms were completely controlled for considerable periods and the patient slept. At other times spasms occurred, but their severity was reduced. The continuation of these spasms in spite of the continuous intravenous myanesin drip necessitated the introduction of myanesin in quantities of 5-10 ml. from time to time; no sedatives were required. After 26½ hours haemoglobinuria occurred, the urine being deep red in colour. The intravenous drip was changed to glucose-saline without myanesin, and within a few minutes the muscle spasms became more frequent and more severe. Paraldehyde was administered intramuscularly, but failed to control the spasms, which increased in severity during the next two hours and terminated fatally.

The final spasm was extremely severe and caused marked cyanosis; *d*-tubocurarine chloride was given and artificial respiration undertaken with the Oxford insufflator, but without effect. At necropsy the naked-eye findings included the following:

1. The bladder contained about a quarter-pint (140 ml.) of urine, which was only slightly smoky in appearance; the colouring matter had decreased considerably in the two hours before death.
2. The kidneys were normal in appearance, colour, and consistency, and showed no abnormality on section. This is surprising in view of the softening which is likely to occur in the kidneys of patients dying from tetanus.
3. In spite of the haemolysing action of tetanus toxin and of post-mortem changes, little or no haemoglobin could be detected by the naked eye in serum removed at necropsy.
4. There were many severe haemorrhages into muscle, including particularly the left quadriceps femoris and the two psoas muscles.
5. The surgical wound in the left knee appeared healthy, but on bacteriological examination a growth of tetanus bacilli was obtained.

Discussion

The first case apparently had an incubation period of nine days, but there is some doubt about this because the site of infection was not definitely proved. It is very

probable that the infection occurred through the splinter wound of the hand, but it was noticeable that no local symptoms of tetanus were associated with it.

In the second case these local signs were fairly marked, spasms of the left leg being severe enough to produce considerable muscular haemorrhages.

It is a generally accepted statement in the textbooks that the toxin of tetanus acts upon the ventral horn cells of the spinal cord. If this be true, the efficacy of myanesin suggests here that its main action is upon the spinal cord, since there is reason to believe that in normal doses it does not act peripherally. Certainly, in the second case, to which such a large dose of myanesin was administered, there was no dulling of consciousness, although sleep did occur from fatigue.

The four-weeks incubation period in the second case was surprising in view of the severity of the illness. It is possible that the million units of penicillin which he had received after operation may have lengthened the incubation period without comparable mitigation of the attack. It may be remarked that, although penicillin destroys the bacillus of tetanus *in vitro*, it is unlikely to do so *in vivo*, because, the bacillus being anaerobic, it flourishes in areas cut off from blood supply and consequently inaccessible to penicillin. Various sources of infection have been considered: the grey wool with which the limb was packed before being put into plaster was "stoved" before use and was separated from the wound by complete sterile dressings and bandages; the sulphanilamide powder which was introduced into the wound was alleged to be sterile; and no other cases have occurred, which suggests that the catgut was not at fault. There remains the possibility that infection had occurred during a previous injury to the knee, of which many were sustained at football, and had lain dormant until activated by the interference with the blood supply which may have occurred following operation.

These cases, although one of them unfortunately ended fatally, indicate not only that myanesin acts efficiently in controlling the spasms of tetanus but also that its use in massive doses will bear further investigation. Tolerance did not develop, which was in marked contrast to the reaction of the first case to sedative drugs.

Haemoglobinuria occurred in the second case, but in the short space of two hours which the patient lived after the myanesin was discontinued the urine had become almost free from haemoglobin. This supports the view that the haemoglobinuria may be temporary and might perhaps be disregarded. The most important practical attribute of myanesin was its ability to control muscle spasms and to relax hypertonus without paralysing the muscles of respiration, so that artificial respiration was unnecessary.

Summary

The reported cases of haemoglobinuria after myanesin are mentioned. Death has probably never resulted from this complication.

The evidence concerning the site of action of myanesin is recapitulated, and its value in tetanus supports the belief that it acts on the spinal cord.

Two cases of tetanus are reported. The first patient was treated mainly by sedatives and *d*-tubocurarine chloride ("tubarine") and received 58 ml. of myanesin. He recovered and had no haemoglobinuria. He did, however, have signs of pulmonary consolidation. The second, a much more severe case, was treated solely with myanesin, which efficiently controlled the spasms until haemoglobinuria developed, after 265 ml. had been given in 26½ hours. The myanesin was then discontinued; sedatives were ineffective, and he died two hours later. During these two hours haemo-

globinuria almost disappeared, and the kidneys were normal to the naked eye and on section.

The entry point of the infection is discussed.

Further investigation of myanesin in the treatment of tetanus seems to be warranted.

We wish to acknowledge the courtesy and promptitude with which a large consignment of myanesin was dispatched to us by British Drug Houses, Ltd., in response to the urgent action of Mr. Foggan, the chief pharmacist.

A "MINOR" INJURY OF THE TERMINAL PHALANX

BY

F. I. POWELL, B.Sc., M.B., B.Ch.

Late House-surgeon, Fracture and Orthopaedic Department,
Royal Infirmary, Cardiff

Terminal phalangeal injuries are often regarded with a great deal of indifference and, indeed, sometimes scorn. They are the Cinderella of hand injuries, and yet these injuries are amongst the commonest in casualty departments, causing as they do a varying amount of pain, discomfort, and unemployment to the patients.

The particular injury under review here is a common one, a crush injury to the terminal phalangeal area, usually caused by a heavy weight—e.g., an oxygen cylinder or metal bar falling on to the finger. The finger is caught by the object and crushed against the floor or a wall, the lesion produced being somewhat characteristic. There is always a degree of "dislocation" of the nail; the proximal end may be dislocated wholly or partially from the nail-bed, the cuticle usually being damaged with this uplift as well. The soft tissue is split, the amount of laceration varying a great deal; there is some oozing of blood; and the radiograph may show a fissure or an appreciable fracture of the terminal phalanx.

I would like to advocate here a procedure that has yielded good results even with the most badly crushed fingers, the essential feature being the removal and replacement of the nail.

Method

The hand is cleansed of any grit and oily material by a good soak and "scrub" in C.T.A.B. Procaine 2% is then injected by a fine needle lengthwise along the margins of the nail (Fig. 1). When the finger is anaesthetized the nail is lifted or cut clean off and placed in C.T.A.B. and then manicured and trimmed with scissors.

On examination of the nail-bed area the amount of laceration and dirt is often surprising. There is always free oozing of blood, and a fracture of the terminal phalanx may be clearly visible. If bleeding is severe the usual attempts to stop it—haemostats or topical thrombin—are made. After cleaning the area with C.T.A.B., suturing of soft tissue is carried out and the nail-bed is sprinkled with sulphanilamide or penicillin powder. The clean nail is then placed in its correct anatomical position and sutures of either horse-hair or silkworm-gut are passed through the

nail at about four points to anchor it to the finger (Fig. 2). The whole is then covered in "tulle gras," a firm dressing is put on, and a plaster shell is finally applied.

FIG. 1.—A schematic drawing of an injured phalanx. Sites of procaine injection (P). The nail is avulsed proximally, showing the nail-bed.

FIG. 2.—Nail replaced in correct position by four sutures.

An injection of A.T.S., A.G.G.S., and 250,000 units of penicillin is given. The dressing is removed a week later, when it will be found that the sutures can be removed without difficulty: the nail does not drop off, as might be expected, but stays on for a variable but appreciable time. There is usually a small haematoma under the nail, but the whole finger is pleasingly free from pain and infection. A powder dressing, with or without another plaster shell is applied for another week. At the end of about three weeks the patient's finger is quite satisfactory and the cosmetic result good. A new nail will eventually form.

On the other hand, in cases in which the nail has been left dislocated proximally excessive granulation tissue constitutes a troublesome complication at the break, and often pus forms under the nail. Where the nail is avulsed and not replaced there is often oozing of blood for a few days, for which repeated dressings of the area may be necessary, and even after two weeks the finger may be very tender.

Recently a man received this type of injury when working in a dockyard. The finger had not been cleaned, but was placed straightway in a plaster cap with just a gauze dressing. When we saw him a month later, he having moved from the town where he sustained the injury, his finger was still in plaster, and on its removal the terminal phalanx was one mass of foul-smelling slough. It took many weeks to get anything like a satisfactory result for him. The method outlined in detail for these injuries is a satisfactory one; it is simple to perform and can be carried out with a slight amount of material. It is well within the range of minor surgery work of general practice, and it can be performed with complete confidence on the practitioner's part.

A memorandum issued by the Department of Health for Scotland states that under the National Health Service hospital almoners should be released as far as possible from office duties and allowed to concentrate fully on the medical social work for which they have been specially trained. The duties of the almoner should properly include investigation and interviews to provide understanding of the social and personal background of the patient, and in particular to give the doctor information of this kind which is relevant to diagnosis and treatment; social action to minimize personal anxieties; helping the patient in his adjustment to home life, to resume employment, or to a continuing disability; and advising on the planning of facilities for patients. At present the supply of trained almoners is well below demand, and it is therefore particularly important that their services should be confined to these tasks for which they have special qualifications. The salary of an almoner holding the certificate of the Institute of Almoners is on a scale of £340—£390 per annum. Head almoners earn up to a maximum of £660.

Medical Memoranda

Dangerous Symptoms after Injections of Heroin (Diamorphine)

It is thought that two recent experiences of the dangers of heroin should be added to the available information.

CASE 1

A woman aged 40 spent a fatiguing day in town with her daughter. She travelled 230 miles by rail, dined on the train, did not fancy the meal, and reached home very tired. Next day she vomited repeatedly, diarrhoea developed, and by evening she appeared to be seriously ill. She sent for X.Y.Z., who had known her well for twenty-five years. He found her pale and rather limp. Her pulse was rapid, the systolic pressure 115 mm. Hg, and the breathing shallow and rapid. She stated repeatedly that she felt very ill. There was no rise of temperature nor any signs in abdomen or chest. He decided to give a morphine sedative to check the vomiting and diarrhoea, and chose heroin, as it is said to be less liable than morphine to cause nausea. In three or four previous cases he had injected 1/6 gr. (11 mg.) of heroin with little apparent effect. He therefore took two tablets of this dose, specially prepared for injection, dissolved them in water, and injected them subcutaneously.

He waited (fortunately) to see the patient comfortable, and was at first gratified to note that her distress diminished; she was soothed and felt sleepy; she remarked drowsily, "It's coming over me." Then, 10 to 15 minutes after the injection, almost suddenly, she became deeply unconscious and unrousable. Inspirations became rapidly shallower, with longer and longer intervals; there was deep cyanosis, with complete muscular relaxation and an imperceptible pulse. The pupils were very small—not quite pin-point. X.Y.Z. reversed his therapeutics. He injected nikethamide 0.5 g., removed the pillows, raised the foot of the bed, sent a very urgent message for another doctor, and began artificial respiration. I arrived in ten minutes. By then respiration had entirely ceased, there were no reflexes, and the extremities were cooling. The only hopeful sign was that the heart sounds were faintly audible and the pulse was occasionally perceptible. A catheter specimen of urine was free from albumin, sugar, and ketones. Lobeline 0.003 g. was injected. Artificial respiration was continued and rhythmic traction was applied to the tongue. Oxygen and carbon dioxide were sent for. The former arrived in fifteen minutes, and its administration quickly lightened the cyanosis and seemed to produce some general improvement. After about twenty minutes the patient began to make very feeble respiratory gasps at long intervals. The intervals gradually diminished and the respirations deepened, so that after another twenty minutes artificial respiration could be stopped, though the oxygen was continued a little longer. By the time the carbon dioxide arrived its use was thought unnecessary.

About four hours after the injection of heroin the patient could be roused sufficiently to recognize her husband and to be spoon-fed with strong coffee. The pupils were still minute, and she continued to be extremely drowsy. Three hours later the respirations again became alarmingly shallow and infrequent and there was cyanosis, but recovery took place without major measures.

Next day the patient was drowsy, weak and feeble, and had contracted pupils. There was much nausea, with some vomiting. Coffee and glucose were given per rectum. Recovery proceeded evenly for five days; then there was some return of nausea, vomiting, weakness, and a feeling of respiratory oppression. In another five days recovery was practically complete.

No further light was obtained on the original illness. No more signs developed; the temperature was never raised; and no albumin, casts, inflammatory cells, or blood corpuscles were found in the urine. Agglutination tests were completely negative for *Salmonella paratyphi* A and B, *Bact. sonnei*, *S. typhi murium*, Gaertner's bacillus, and *Br. abortus*. No non-lactosing-fermenting bacilli were obtained in cultures of the faeces. The daughter was unaffected.

CASE 2

This patient, a woman aged 65, had arteriosclerosis, a systolic blood pressure of 230 mm. Hg, and was liable to attacks of severe epistaxis. X.Y.Z. was summoned at 2 a.m., with a report of very severe vomiting for an hour, the face being drawn to one side, and numbness of the right hand. On arrival he found no anaesthesia or paresis, and could not ascertain to which side the face was thought to have been drawn. The patient and her relatives were very restless, anxious, and alarmed. X.Y.Z. injected 1/6 gr. of heroin subcutaneously, taking a tablet from a fresh tube. The patient seemed inclined to settle.

He returned in half an hour and found the patient unconscious, pale, and pulseless. Her jaw was dropped, her features relaxed, her

eyes half open, and the pupils very small. She was breathing only by spasmodic stertorous inspiration at long intervals. Artificial respiration was started, and this, with various vigorous sensory stimuli, roused the patient sufficiently to ensure automatic breathing. She remained very drowsy till next morning, but no more alarming symptoms developed.

These two cases do not form an extensive series, but further experience is not being invited. I have to thank X.Y.Z. for collaboration in this note.

CRANSTON WALKER, M.D.

Skull Closure by Acrylic Plates

This note describes two cases of large frontal skull defects treated in India by means of acrylic plates. The method of Small and Graham (1945) was adopted with minor simplifications. The impression material used was dental wax, sterilized by heating to smoking temperature then autoclaving. A rim of lead was used to hold the wax, and allowed of firm pressure. No undercuts were reproduced—an advantage in this particular work. The plate was of skull thickness, perforated, and curved by eye to fit a model of the skull.

At the first operation the skull defect was step-cut by a cylindrical dental burr and a chisel, and a key was introduced at two points. At the second operation, performed a month later, the completed plate was wired in with stainless steel. The plates were sterilized by scrubbing with soap and water, followed by immersion in 1% mercuric chloride in water for three days. This method produced no warping or softening of the acrylic substance and no deposition of heavy metal on the plate. These Indian patients were transfused with whole blood at the first operation to keep up a satisfactory level of haemoglobin, and chemotherapy and aspiration of fluid were employed on the first, third, and fifth days.

CASE HISTORIES

Case 1.—This patient, a Gurkha, had lost about two-thirds of his left supraorbital margin, the anterior portion of the orbital roof, and a large area of frontal bone. Following the wounding he had had a fungus cerebri for about six months. At the first operation a rotation flap was used to cover the defect with sound scalp. The result remained satisfactory when he was last seen three months after the second operation.

Case 2.—This was a Sikh who had lost a large portion of the fronto-temporal region. Debridement by Major G. M. Lunn, R.A.M.C., 72 hours after the wounding, secured first-intention healing. The plate was inserted three months later, and continued to be satisfactory during two months' observation.

Acrylic resin, of all inert materials, has a strong claim for suitability in frontal defects, where by its use admirable cosmetic results can be achieved by the exercise of ordinary operative skill. The limiting factor in regard to size is the tension of the overlying scalp, not the durability of the plate. Granulation tissue grows through perforations in the plate and improves blood supply to the scalp, but ties it down and reduces its mobility.

Thanks are due to Sergeant Dewar, A.D. Corps, for preparing the trays and plates, and to Major N. Reichman, R.A.M.C., for his aid with the anaesthetics and the drilling operations.

Reviews

THE ANNUAL MEETING, 1948

Proceedings of the Annual Meeting, 1948. British Medical Association. (Pp. 415. £1 15s., postage 1s. 3d. extra.) London: Butterworth and Co. 1949.

The B.M.A. is to be congratulated on following a precedent, set at the Cambridge meeting in 1919, of publishing in one volume the papers given at the Association's meeting last summer. Between Sir Lionel Whitby's presidential address on "The Changing Face of Medicine" and Sir Henry Dale's popular lecture, "Accident and Opportunism in Medical Research," are sandwiched the proceedings of the nineteen scientific sections. To read the titles of the papers reveals the breadth of the discussions and the comprehensive manner in which all the growing points of medical science were reviewed.

From such a wealth of material it is difficult to choose communications for special comment. In the combined meeting of the Sections of Medicine and Surgery, Dr. R. H. Smithwick's review of his results from the surgical treatment of hypertension will be read with interest. Mr. W. L. Harnett's statistical survey of the results of treatment in carcinoma of the breast is an actuarial *tour de force* of outstanding importance, and will provide a yardstick for assessing the value of treatment for years to come. Additional random selections, such as the discussions on neonatal mortality and morbidity, on the radiological changes in the small intestine in nutritional disorders, and on the antihistamine substances, show the wide scope and the topical character of the Sections' deliberations. All who attended the Association's first annual meeting since 1939 will be anxious to possess this book, both for the scientific value of the communications it contains and as a reminder of the peaceful charm and gracious hospitality of Cambridge.

R. BODLEY SCOTT.

B.C.G. VACCINATION

Vaccination par le B.C.G. par Scarifications Cutanées. By L. Nègre and J. Bretey. Preface by Professor A. B. Marfan. 5^{ème} édition, revised and enlarged. (Pp. 116; 10 figures. 180 francs.) Paris: Masson et Cie. 1947.

Most of the early work on vaccinating human beings with B.C.G. was done by the oral route. The disadvantage of this method was that only about one-third of the vaccinated subjects became sensitive to tuberculin after it. The introduction of the intradermal method, now so widely used in Scandinavia, remedied this defect but brought with it disadvantages such as local ulceration and occasional glandular enlargement. Rosenthal, in Chicago, experimented with multiple-puncture and reported very favourable results with it, obtaining early development of tuberculin sensitivity and absence of any unpleasant local reaction. Dr. Nègre and Dr. Bretey, in Paris, modified this method, replacing skin puncture by scarification. This monograph records their findings.

The method is simple and resembles that used with smallpox vaccine lymph. The skin is cleaned, a few drops of a fresh suspension of B.C.G. containing 75 mg. of organisms per ml. are placed on it, and a suitable number of scarifications are made through the drops with a sharp needle. The number and length of the scarifications vary from four scratches each 0.5 cm. long in the newborn infant to ten scratches each 1.5–2.0 cm. long in the adult. A simple compress soaked in the remains of the B.C.G. in the phial is applied to the site of inoculation and removed 24 hours later. The small scabs become detached in four or five days. After three to four weeks the scratches become red and swollen, looking rather like a keloid. This inflammatory reaction gradually disappears, and in two to five months a barely perceptible linear scar remains. A focal glandular reaction is rare; it has been reported 30 times in 70,000 vaccinations.

Tuberculin sensitivity develops three to four weeks after vaccination. The figures provided are incomplete, but they suggest that about 90% of vaccinated persons react to 0.1 ml. of 1/100 tuberculin in one to three months. Revaccination is

recommended if Mantoux-conversion does not occur. Infants born into tuberculous families should be segregated, tested with tuberculin twice at two months' interval, and not vaccinated unless both tests are negative. They should not be returned to their families until they have become tuberculin-sensitive. Every six to twelve months they should be retested, and vaccinated again if they become negative. The scarification method has the double advantage of simplicity and innocuity; provided experience shows it to confer as high a degree of allergy as that following intracutaneous inoculation or multiple puncture, it may well be adopted as the method of choice.

G. S. WILSON.

HOMOSEXUAL BEHAVIOUR

Sex Variants. A Study of Homosexual Patterns. By George W. Henry, M.D. With sections contributed by specialists in particular fields. Sponsored by Committee for the Study of Sex Variants, Inc. (Pp. 1,128; illustrated. £2.) New York: Paul B. Hoeber, Inc. London: Hamish Hamilton. 1948.

This ponderous volume adds one more to the numerous and interesting American studies on variations in sex life. The subject is not perhaps quite so important to warrant such an enormous expense of labour. Such studies as have been made of marriage, for instance, have shown that deviations less extreme than homosexuality from the average pattern of sexual behaviour are of less consequence for success or failure than are the temperaments of the partners. The medical significance of sex deviations is even less than their social importance; it has yet to be shown that homosexuals are more liable to psychiatric illness than are normal people. American psychologists and psychiatrists seem to be constantly holding up their hands in wonder at the great range and variety of human sexual behaviour, and to have a tireless delight in cataloguing its details. Once the point is taken—and it was made many years ago by Havelock Ellis—that so-called perversions of all kinds are shown to a minor degree by a considerable proportion of healthy and socially valuable members of the public, there seems little possibility of further advance along the line of mere description.

Dr. Henry's book is almost purely descriptive. By far its greater part is taken up by long, intimate, and detailed histories of forty homosexual men and forty homosexual women. This is a great improvement on the usual convention of obtaining data by questionnaire, on whose reliability little confidence can be placed. He gives the family histories *in extenso*, with fairly vivid sketches of the personalities of the nearer relatives and of early emotional life. The life history of the subject, not only its sexual aspects, is fully described, and there are anthropometric records of skeletal measurements and secondary sex characters. The last are the only findings dealt with statistically; and it is disappointing, if not unexpected, that so little emerges.

Dr. Henry provides no discussion and no conclusions, but he has six pages of "Impressions." He believes that the homosexual is in part a by-product of civilization, and is so because of his inability to maintain a home and rear children. The deviation from normality is due to constitutional deficiencies, to the influence of family patterns of sex adjustment, to lack of opportunity of normal development. Tendencies to femininity in the males and to masculinity in the females of a family are likely to result in the appearance of homosexuals in the next generation. People are more and less of one and the other sex, and not scientifically classifiable as fully male or female. The male is more vulnerable than the female to distortions of psychosexual development. This is practically all that is said on the subject of aetiology.

The main role in both causation and prophylaxis is assigned to sex education. He makes some sensible if unoriginal remarks on social aspects. He condemns present legal defences; society should classify homosexuals into those who are and those who are not apt to offend, and have different methods for dealing with either. Finally, in his comment that males should be encouraged in tendencies to masculine aggression, females in the converse attitude, Dr. Henry makes an interesting reflection on American society. Gorer has discussed the American system of educating boys almost exclusively by school-mistresses, and puts down to it male lack of dominance

and homosexual tendencies which need constant defence; and according to the Kinsey Report 37% of American males have some homosexual experience. So it may be there is force in Dr Henry's recommendation.

PHYSIOLOGY FOR STUDENTS

Human Physiology. By F. R. Winton, M.D., D.Sc., and L. E. Bayliss, Ph.D. Third edition. (Pp 592; 248 illustrations 25s) London: J. and A. Churchill, 1948

This work was deservedly popular with medical students in its earlier editions, but the last one has been out of print for some time, and the appearance of the new edition has been hopefully awaited by students and teachers because there is a lack of small textbooks of physiology that can help the student by presenting the subject simply and in good perspective so that it can be seen as a whole. Teachers in general are fully aware of the recommendations, so often made, to review their courses often and to prune them of unnecessary detail and of material irrelevant to the medical student. A similar duty is laid upon the authors of textbooks.

"Winton and Bayliss" is a work with a point of view. According to the preface the book is intended to present a "coherent picture of the whole subject" to the medical student, in whom the "attitude of an alert explorer" is to be encouraged, and on this claim it must be judged. It seems to be less successful in its aim than the previous editions were. The book is longer, although there are fewer pages because of resetting and the use of smaller types, it is well up to date. Many of the diagrams have been redrawn and new ones added, and yet one has some uneasiness about its worth as a whole to the medical student. There is much factual information; indeed, in some chapters, particularly in those on the nervous system and renal function, a conflict between the necessity of including facts and a desire for brevity may have made understanding difficult for the average student. The authors discuss the various systems in fairly conventional fashion, but there seems to be a lack of balance between different chapters in the treatment and in the amount of material included. This is probably because, besides the two named authors, there are thirteen other contributors who have written one or more chapters on the subjects in which they are specialists. This is a trend which has appeared already in the compilation of larger textbooks, and it is noteworthy that two standard American works have now become collections of monographs. The reason given, of course, is that it is impossible for any one individual to keep in touch with the advance of knowledge on all fronts. Nevertheless, if a book is to be written by a committee it seems desirable that it should come from one laboratory and have a common viewpoint, or alternatively that editors should overwrite contributions quite ruthlessly. As it is, the chapters in this book seem to lack a freshness and individuality that might have been expected—only one or two of them are likely to inspire the student—and the authors have not supplied the thread to bind them into a whole.

The book will be popular because of its moderate size and its former reputation, but opportunities have been missed of introducing students to physiological thought and outlook by relying too much on experts and diversity of interests.

A HEMINGWAY.

It is somewhat paradoxical that the authors of *Milk Products* (Dr Wm Clunie Harvey and Mr. Harry Hill, F.R.San.I., second edition: H. K. Lewis: 30s.) should have chosen to re-edit their book on milk products at a time when so many of the articles they discuss are unobtainable in this country. Ice-cream is but a caricature of its real self, cream is unobtainable, and the processed milks are in short supply. And what the effect on cheese-lovers will be of reading about the mode of manufacture of Lancashire, Wensleydale, Stilton, or Blue Vinney among the English cheeses, or of Prie, Limburger, or Pont l'Évêque among the foreign, is difficult to conjecture. However, the book is primarily intended not for lovers of good food or for the nutritional expert but for public-health workers who are responsible for controlling the hygienic quality of the finished product. For their need it caters well. The new edition, which has been brought fairly well up to date, contains 80 illustrations of manufacturing plant, and should be particularly useful to sanitary inspectors.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Collected Papers of the Mayo Clinic and the Mayo Foundation Edited by R. M. Hewitt, B.A., M.A., M.D., and others Vol 39 (Pp 871. 63s) London: W. B. Saunders 1948

Papers presented during 1947

Racial Variations in Immunity to Syphilis By C. N. Frazier, M.D., and Li Hung-Chiung, M.D. (Pp 122. 14s) London: Cambridge University Press 1949

A study of the different responses to syphilitic infection in Chinese, Europeans, and Americans

Studies of Chronic Pyelonephritis. By F. Raaschou (Pp. 260 Kr. 20.) Copenhagen: Ejnar Munksgaard 1948

A translation of the original Danish monograph

The Achievements of BCG Vaccination. By G. Hertzberg (Pp. 224 No price) Oslo: Johan Grundt Tanum 1948

A study based on the work of the Tuberculosis Department of the Oslo Public Health Service

Physics and the Surgeon. By H. S. Souttar, D.M., M.Ch., F.R.C.S. (Pp 60 7s 6d) Oxford: Blackwell Scientific Publications 1948

Physics applicable to surgery

Les Fondements de la Géographie Humaine. By Max Sorre Vol. 2 (Pp. 608. 1,100 francs) Paris: Armand Colin 1948

A treatise on the adaptation of man to his environment

Exposés Annuels de Biochimie Médicale Edited by M. Polonovski. 9th series (Pp 318. 1,000 francs) Paris: Masson et Cie. 1948.

A collection of twelve lectures in biochemistry from the Faculty of Medicine of Paris

Twenty-third Meeting of the Northern Surgical Association. Official Transactions Edited by E. Dahl-Iversen, M.D. (Pp 502 Kr. 24) Copenhagen: Ejnar Munksgaard 1948.

SICKNESS IN ENGLAND AND WALES

When the second World Health Assembly meets in Rome on June 13 this year a comprehensive programme and budget for 1950 will be submitted to it by the WHO Executive Board. The main attack is on communicable diseases in under-developed areas of war-devastated countries, and other proposals are concerned with the promotion of maternal and child health and mental health, the prevention and treatment of tuberculosis and of venereal diseases, health education and nutrition, sanitation, and occupational hygiene. Among the subsidiary projects is an extension of WHO's work in health statistics. Perhaps this is rightly classed as subsidiary, and certainly many persons would regard it as prosaic and dull, yet much of the fundamental work listed above must inevitably be based upon sound vital statistics. Without them the selection of the most urgent problems to attack is seriously handicapped, and the measure of the effects of that attack is almost impossible. This, indeed, was clearly recognized by the first Assembly in its adoption of the Sixth Revision of the International List of Causes of Death, now greatly expanded to cover causes of sickness as well.

It is in this latter field—the frequency and nature of illness—that an extension of work in health statistics is to be most desired, and such a development is in fact being given much attention in many countries. "The health of the nation was never better" is, perhaps, true, but it would be more convincing if we knew how often it was ill as well as the rate at which it died. To collect comprehensive statistics of sickness is not, however, an easy task. We have already discussed the proposal of the Ministry of National Insurance to study a sample of the sicknesses leading to claims to benefit¹; whatever the value of these records—and it may prove considerable—the resulting statistics can relate only to the working population and only to those who lose time from work (usually for four days or more) because of their illness. The Ministry of Health is experimenting with sample returns of patients entering hospital; taken alone, these can show only a small part of the picture of the incidence of illness. Some of the advantages and disadvantages of these statistics were argued at length at a meeting of the Royal Statistical Society.² Three other sources of national figures—the notification of infectious diseases, the sickness investigation conducted by the Social Survey, and the food rationing figures—are discussed by Dr. Percy Stocks with customary statistical skill and imagination in the second of the

occasional publications issued this week by the General Register Office.³

The best known of these sources is undoubtedly the first group—the notifiable diseases—the statistical value of which was greatly increased in 1944 by the publication of the quarterly returns for different age groups for each sex. It is well known that notification is not complete, and Stocks compares the recorded rates of attack with other available data to assess the degree of completeness. Thus at the notified rates of scarlet fever in 1944–7 approximately 10% of children would be attacked before age 15; this figure agrees reasonably well with the number of children whose histories have revealed an attack of scarlet fever before their fifteenth birthday in such different places as English public schools, the borough of St. Pancras, and towns in the U.S.A. On the other hand, from the notifications of whooping-cough it could be calculated that only 13–14% of children are attacked before the age of 15, whereas all available data on the history of previous attacks collected in the U.S.A. and this country indicate that the true figure is 60–70%. By these and similar means Stocks is led to conclude that notification is fairly complete for acute poliomyelitis, cerebrospinal fever, diphtheria, and scarlet fever, and that the notifications of other diseases are about 90% of the total in the case of respiratory tuberculosis, 80% in the enteric fevers, two-thirds in measles, one-third to one-quarter in pneumonia, one-quarter to one-fifth in whooping-cough, and a merely fractional amount in the case of dysentery. He is here, of course, thinking of illness in terms of typical clinical cases and excluding sub-clinical attacks, doubtful cases, and evidences of infection without definite clinical symptoms. He speaks with some emphasis about the last, stressing that the criterion for notification is that the person is "suffering from" the disease and that "any departure from this criterion is likely to lead to confusion not only in statistics but in administration." Diagnosis can be greatly aided by bacteriological, biological, and radiological tests, but the tests themselves are not measures of disease incidence. Clearly the distinction must sometimes be very hard to draw. He maintains, for instance, that "thoracic shadows on a skiagram" do not constitute the presence of disease "unless accompanied by symptoms attributable to the disease." This may lead to some awkward problems. For instance, two patients might be found by mass radiography to have early pulmonary tuberculosis, neither having any symptoms or knowledge of departure from health; one then goes to a sanatorium and the other refuses treatment. Are both, one, or neither notifiable? With such tests the notifications of some diseases may well rise artificially, since cases are more easily detected, while the numbers of others may rise if in the new Service the doctor's help is more frequently invoked than in the past. Study of recent weekly returns provides no evidence in the case of the common infectious diseases of childhood that that is yet happening.

The technique of the Social Survey investigation into sickness incidence is the interviewing at the beginning of each calendar month of small but representative samples of the whole civilian population aged 16 and over. A note is made of the illness and injuries reported by each person to have taken place during each of the two preceding

¹ *British Med. J. Journal*, 1949, 1, 533.

² *Re. Statist. Soc.*, 1948, 111, 14.

³ *Survey in the Population of England and Wales in 1944–1947*, 1949. London: H.M.S.O.

calendar months. From this material Stocks calculates a number of rates. Thus in the year 1946-7 each 1,000 men aged 16 or over reported an average of 1,169 illnesses and injuries per month, while the corresponding rate per 1,000 women was 1,617. Alternatively, the number of persons ill during the month may be used in place of the number of their sicknesses; this reduces the above rates to 619 per 1,000 men and 713 per 1,000 women. To another figure Stocks gives the rather unattractive name of the *aegrescence rate*, which he defines as the number of persons who started an illness during a defined period of time; it leaves out of account those who continued to suffer from an illness starting previously. Thus in 1946-7 out of each 1,000 civilians an average of 44 men and 51 women per month started a defined illness (other than minor), and 275 men and 336 women started a minor or ill-defined complaint. The mean days of incapacity and the numbers of medical consultations can also be computed. At these adult ages the latter figure was about five consultations per person per annum, rising from four per person at ages 16-45 to seven or more at ages over 65.

While it is clearly necessary at present to experiment with various forms of calculation and presentation, there does seem to be some risk of obscuring the wood with too many trees. It is to be hoped it will be possible in time to set out the basic sickness incidence in perhaps a couple of rates without any serious loss. Some workers might feel that it would be no serious loss if the mass of very minor or ill-defined illness was eliminated instead of, as at present, frequently dominating the picture. On the other hand, it can be retorted that the whole *raison d'être* of the Social Survey approach lies in these minor illnesses, since they call for no medical attention or sickness benefit, and their contribution to the record of ill-health can be found in no other way. The statistics to which they lead indicate, for instance, that one person in eight developed a cold during the average month—a figure suggesting that each adult has an average of 1.4 colds per year—that about one in 500 developed migraine in a month, one in 2,000 herpes, one in 6,000 ringworm, one in 14,000 scabies, and one in 17,000 mumps.

Stocks endeavours to check the accuracy of diagnosis in these self-reported illnesses by comparing the rates of incidence calculated from these figures with the rates calculated from figures obtained from the priority food rationing scheme or from notifications of disease. On the whole the agreement is encouraging, though the comparison necessarily lies only in the field of serious and well-defined complaints; much more work is necessary on other illnesses. These statistics of priority allowances were kept by the Ministry of Food at the request of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council. The diseases upon which Stocks reports are active tuberculosis, gastric, duodenal, and anastomotic ulcers, dyspepsia due to other causes, diabetes mellitus, and thyrotoxicosis; for all of these extra allowances of milk were allotted. At the end of 1947 there were registered in England and Wales just under 100,000 diabetics, or 231 per 100,000 population; 118,000 cases of respiratory tuberculosis, or 278 per 100,000; and nearly 670,000 cases of ulcer or dyspepsia (roughly divided into

the ratio of 2:1). Allowances for thyrotoxicosis numbered 4,467, or 11 per 100,000 persons—women predominating in the ratio of 3½:1. The incidence of this complaint in the northern counties was considerably below that reported in London and the South. In the present report, however, Stocks limits himself almost entirely to the assessment of sickness in the population as a whole. Its measurement in local communities is of more particular interest to many persons—the medical officer of health, for instance—and this, the Registrar-General promises in his preface, is not being overlooked.

AIR TRANSPORT OF THE SICK AND INJURED

The credit of being the first to transport a wounded man by air belongs to a French pilot, Captain Dangelzer, who flew a wounded Serbian airman to safety during the retreat of the Serbian army in 1915.¹ The French were also the first to introduce air ambulances; this was in Morocco in 1918. The Royal Air Force first transported casualties by air in 1919, during the war against the Mad Mullah in Somaliland, when three patients were moved, one at a time, 175 miles on stretchers placed inside the tail-end of the fuselage of a DH9.^{2,3} The R.A.F. began to develop air ambulances during the years 1920-2 and put them into use in Iraq in 1923, when 359 patients were transported—198 of them being cases of dysentery among British troops operating in Kurdistan. Even then most of the casualties were taken in troop-carrying aircraft convertible into air ambulances at short notice. The first organized R.A.F. air-ambulance service in this country was based at Halton during 1925 and 1926 and served a radius of 100 miles; it was disbanded in 1927. From that time until the outbreak of the war of 1939-45 the number of Service patients transported each year by air (mainly in the Middle East and India) varied between 66 and 418. In 1937, when the R.A.F. general hospital in Bagdad was moved some 90 miles to Habbaniya, the majority of the patients were transported by air. It was found, however, that to reserve aircraft solely for ambulance purposes was uneconomic, and consequently until the outbreak of hostilities in 1939 troop-carriers were used as air ambulances when required.³

At the beginning of the war there was no organized air-ambulance service, but in 1941 a service was established in the Western Desert and another in the United Kingdom for the benefit of the garrisons in the outlying Scottish islands. The air-ambulance service in the Western Desert operated with aircraft provided by the Australian Air Force, the South African Air Force, and the R.A.F., and during the campaigns of Wavell, Auchinleck, and Montgomery about 60,000 patients were moved by air from forward areas to the base. From then onwards the transport of casualties by air in the various theatres of war increased rapidly, so that by V.J. Day the R.A.F. had carried approximately 400,000 sick or wounded patients, most of whom were in the Army. This fine performance

⁴ Jackson, R. C., *Lancet*, 1945, 2, 543.

was carried out without a single mishap, though over 30,000 separate flights were made and much of the flying was done from forward landing strips near the enemy, over jungle, mountains, and sea, and in all conditions of weather. The maximum number of casualties transported in a single day during the Western Desert campaign was 400, and during operations in Normandy 934.^{3 4}

The air-ambulance service did much to maintain the high morale of our Forces. The patients selected for transport to appropriate treatment centres were those for whom early treatment was necessary either to secure a successful result or to ensure their early return to duty. Priority was given to patients with facio-maxillary injuries, burns, perforated wounds of the globe of the eye, fractures of the limbs and spine, and head injuries. Patients suffering from certain conditions were not considered suitable for air transport until after appropriate treatment in forward areas: among these conditions were shock, recent abdominal and thoracic wounds, recent severe haemorrhages, gas gangrene, lobar pneumonia, pneumothorax, angina pectoris, and coronary occlusion. Oxygen and blood transfusions were given as required *en route* by specially trained nurses and nursing orderlies. During the war all the helicopters available were needed for operational duties in the field. This type of aircraft can now be safely employed for the transport of casualties back from the most advanced landing strips, and the Royal Air Force is using them to develop a casualty evacuation service. In war, air ambulances have other advantages besides getting the wounded back to a casualty clearing station or hospital in the shortest possible time with the minimum of discomfort; they reduce the numbers of doctors, nurses, and orderlies employed on the evacuation of casualties and they free the lines of communication from road ambulances and ambulance trains.

For civilian sick an air-ambulance service was inaugurated in 1933 by Scottish Airways to serve the isolated Western Isles of Scotland; ordinary passenger planes, based at Renfrew, were used. Patients were taken to hospitals in Glasgow, or doctors and nurses were taken to the patients. In 1935 certain Scottish county councils agreed to bear part of the cost of air ambulances used in cases of emergency. The Department of Health for Scotland now operates this scheme through the regional hospital boards and British European Airways. The number of patients transported each year is about 300. Just before the war began an air-ambulance service was established for the transport of patients from the Channel and Scilly Isles. In 1941 the Air Transport Auxiliary formed an air-ambulance service, using stretcher gear built into passenger-carrying aircraft. The number of aircraft in this service rose to 60, and these carried nearly all the Service sick and wounded who were transported by air within the British Isles.

Mainly as a result of the lessons learned during the war the British Airways Corporations have been able to work out a policy for the benefit of all invalids proposing to travel by air. In a paper appearing elsewhere in this issue the chief medical officers of the three British Airways Corporations—Air Marshal Sir Harold Whittingham, Dr. A. Buchanan Barbour, and Wing Commander J. C. Macgown give authoritative information about how a patient's fit-

ness for air travel should be assessed. It is interesting to note that in the future most aircraft will be "pressurized"; this means that the majority of invalids will be able to travel by air with as great, if not greater, comfort than by road, rail, or sea.

NATIONAL TRIAL OF B.C.G.

At the London meeting of the International Conference of Physicians in 1947 Professor W. H. Tytler remarked that Great Britain had "the questionable distinction of being the only one of the major countries which has contributed little or nothing to B.C.G. vaccination."¹ According to recent and widespread reports in the daily press it appears that this situation is shortly to be righted, though the announcement of national trials is, we understand premature and an official statement is not to be expected for another two or three weeks. It is, however, known that early last year the Ministry of Health set up a distinguished committee to advise it on the nature and scope of the trials of this vaccine, and the details of this committee's conclusions will be awaited with great interest. According to the parliamentary correspondent of *The Times*² volunteers are to be sought among nurses and medical students and among young persons in contact with tuberculous patients in their homes.

Nurses, of course, have long been considered a group in need of special protection, and it is certain, therefore, that they would be brought into any trial in this country. The difficulty may be to secure enough in numbers, particularly as some hospitals will not be in a position to take part in the experiment at all. For example, there are hospitals which do not allow tuberculin-negative nurses to work in their tuberculosis wards. If the volunteers are to be divided into two groups—those to be vaccinated with B.C.G. and those to be held as controls—then the unvaccinated group in hospitals with such a regulation would not be allowed in contact with cases of tuberculosis and the vaccinated group would be in contact with them. A comparison between groups exposed to such different risk would clearly be of little value. Any effective trial with nurses and medical students requires two groups that will subsequently have a comparable exposure (on the average arbitrarily divided into the vaccinated and unvaccinated).

Another likely field of inquiry would be young adolescents leaving school and going into factories or offices—particularly, perhaps, young women, in whom the peak of mortality from tuberculosis lies in the early adult age groups. Here again the inquiry will need to be widespread and to cover many thousands of persons. The attack rate from tuberculosis in this country is such that decisive differences between vaccinated and unvaccinated are not likely to be revealed in any study with small numbers. This line of investigation might well be linked up with the mass-radiography campaign. The volunteers must agree to take part in what is, it must be made clear, a national experiment.

⁴ *Ibid.*, 1946, 2, 125.

⁵ *Ibid.*, 1948, 1, 1126.

⁶ *Ibid.*, 1948, 1, 1129.

A third group of great importance comprises babies and young children in homes where there is a case of open tuberculosis. To include these in a controlled trial would be very difficult, for according to the advocates of B.C.G. the child must be removed from the home, proved to be uninfected, and then made tuberculin-positive before return. What of the controls? They too must be removed from the home and proved uninfected; they will not become tuberculin positive, for no vaccine will be given them. Can they be returned to a still infective home, even allowing for doubts about the efficiency of B.C.G.? As Professor Bradford Hill pointed out³ in this *Journal* last year, such demands may, too, in everyday life "materially reduce the field in which B.C.G. can operate, since it necessitates pre-detection of the tuberculous household and removal of the infant at birth for some months." It may be, therefore, that B.C.G. should be tested under the normal conditions of life without removal of the child from the home. That might not be ideal, but it is realistic.

A fourth group in this country might be found among mental defectives or the mentally deranged in institutions. Such patients have relatively high death rates from tuberculosis and, being in institutions, can easily be followed up after vaccination. The follow-up, indeed, is likely to be one of the major difficulties in this national trial. Very large numbers of persons must, as we have said, be brought into it, and they must be followed up for at least 3-5 years. Uniform tuberculin-testing, uniform x-ray photography, and, above all, uniform statistical records of illness and death must be developed and maintained. Uniformity is the paramount issue. Regional hospital boards and local authorities might, as has been suggested in the *Press*, administer the schemes, but if they are not centrally guided and controlled it is almost certain that the schemes will fail. It would seem wiser, as was indeed suggested in 1946,⁴ to place such a difficult but practically important piece of research in the hands of some such official body as the Medical Research Council, which has the necessary field experience of such trials.

Professor Wallgren,⁵ of Stockholm, has pleaded that B.C.G. be given a fair trial, and H. Malmros⁶ recently described in this *Journal* his experience with it in Sweden. This country now has the opportunity, and will, we trust, make both a fair and a statistically sufficient trial; otherwise we shall merely add to the many reports that collectively provide presumptive but not wholly convincing evidence.

THE BRITISH MEDICAL GUILD

The second of the Special Representative Meetings held last week in B.M.A. House had before it a report of the Council on the constitutional position of the B.M.A., a report drawn up in response to a request by the Representative Body in Cambridge last year that the Council should explore the possibility of setting up a body equivalent to a trade union.

This Report has been published,¹ and comment on it appeared in these columns in the *Journal* of Feb. 26, 1949.

The Special Representative Meeting, after an interesting debate, accepted the Council's recommendation

"that for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, a new organization be established in the form of an independent board of trustees with power to organize and finance collective action by the profession and to provide financial compensation to practitioners suffering financial hardship through participation in such collective action."

This new organization, which is to be called "The British Medical Guild," will be constituted in accordance with the Trust Deed drafted by the Association's solicitors. The trustees of the Guild will be members of the B.M.A. Council for the time being. The Guild, in fact, will be a legitimate and almost identical twin of the B.M.A., and its policy will be that laid down by the Representative Body. As a separate legal entity it will be able to do those things which by its constitution the B.M.A. is unable to do. It will be, in effect, a Trust Fund supported by voluntary contributions, and the trustees will be able to use the money thus collected as a financial weapon in disputes and as a source of compensation for medical men who may suffer financial loss as a result of taking action advised by the Guild. The Guild will not have a separate membership but will be organized centrally and locally in much the same way as was the Independence Fund set up last year. If the Association's armoury is to be well stocked it is essential that those members of the profession other than general practitioners should subscribe to this Fund so that in an emergency it can indeed be effective. The general practitioners under N.H.S. have for years had their own *Defence Trust* and continue to subscribe to it in the present National Health Service. This Fund is under the control of trustees who are members of the General Medical Services Committee, and no doubt the trustees will consider the question of making a contribution from its Fund to the Trust Fund under the British Medical Guild.

Although the Representative Meeting passed the Council's motion by a very large majority many doubts were expressed about the wisdom of the course in a series of excellent speeches. The representative of the Lothians Division ably supported an amendment to the effect that the Association as at present constituted was competent to undertake any necessary negotiations on behalf of the profession. The B.M.A., he believed, stood as one of the greatest democratic institutions of this country, and the fact that it could not coerce its members in times of difficulty was a source of strength to it. Another speaker considered that the proposed Guild was as near to a trade union as the Council could desire without incurring legal difficulties, and it was obvious from the discussion on motions advocating the formation of a trade union that this was something the Representative Body did not want. One speaker drew attention to the fact that the B.M.A. had approved using the Whitley machinery for negotiations on the remuneration of the profession. If negotiation breaks down, then the matter would be submitted to arbitration. If two parties submit a matter to arbitration it is assumed that they agree in advance to accept the decision of

¹ *British Medical Journal Supplement*, 1949, 1, 95.

the arbitrators, and from this the conclusion would seem to follow that the Trust Fund would not be used to resist such a decision. Dr. H. Guy Dain, the Chairman of Council, however, pointed out that the Whitley machinery covered only certain aspects of the contract between various sections of the medical profession and those who pay them. Attaching his remarks closely to the motion submitted by the Council, Dr. Dain gave cogent reasons for the establishment of a British Medical Guild, and when the three propositions of the Council's motion were put to the Meeting each one was passed by more than the necessary two-thirds majority. It now remains for the medical profession to back up the policy approved by the Representative Body and to subscribe to the Fund when the proposed methods of doing this are made public.

The constitution of the B.M.A. has been moulded in response to the new situation in which the medical profession has found itself since July of last year. Some aspects of this were commented on at the Special Representative Meeting which considered the question of remuneration of general practitioners. The General Medical Services Committee, while a Committee of the B.M.A., is nevertheless autonomous, and, acting for the general practitioners in the N.H.S., submitted to the Ministry of Health the case for an increased betterment factor. The Consultants and Specialists Committee of the Association is also autonomous. At first glance it would seem that these two autonomous bodies might detract from the authority of the Representative Body as the policy-making organ of the B.M.A. For years the Insurance Acts Committee was similarly an autonomous body and yet there was never any point of conflict between it and the Representative Body. So on the basis of this experience there would seem to be no reason to expect marked divergence of views and actions between the two new autonomous committees and the Representative Body. Nevertheless, the situation is to some extent changed by the fact that a large majority of the medical profession is now working under the National Health Service Act, and the Representative Body will watch the evolution of these two new committees with interest and sympathy. No doubt as time goes on their motives, decisions, and actions will become more and more closely interlocked, and the Representative Body will be eager to lend its powerful support to the actions of any one section of the profession whether general practitioners, consultants and specialists, or those working in the Public Health Service. And for all these groups there will be the economic instrument provided by the British Medical Guild, legally separate from, but closely parallel to, the British Medical Association.

REMUNERATION OF GENERAL PRACTITIONERS

The Special Representative Meeting to consider the remuneration of general practitioners under the National Health Service Act met in B.M.A. House last week and had presented to it the Report of the General Medical Services Committee which had been accepted by the

Conference of Local Medical Committees on March 12. Dr. S. Wand, Chairman of the G.M.S. Committee, moved that the S.R.M. should give its fullest support to the Conference of Local Medical Committees in its request to the Ministry of Health that the betterment factor of 70% should be applied to the gross remuneration of general practitioners. Dr. Wand stressed three points: (1) that the betterment of 34% applied to gross remuneration by the Government bore no relation to the present-day value of money; (2) that there were now two or three thousand more doctors in the Service than the 17,900 on which the Spens recommendations were based; and (3) that there were errors in distribution. He stressed that general practitioners had, under harassing conditions and working unreasonable hours, carried out their part of the contract and asked whether the Minister of Health had carried out his. This dissatisfaction with the Minister's attitude was again expressed later on in the Meeting in the form of a rider moved by the Chairman of Council to the effect that the Representative Body expressed its great concern that the Minister, having received the general practitioners' representations more than two months ago, had not yet made the necessary adjustments to implement the Spens recommendations so that the increased payments could be made in this quarter. "This delay shows disregard for the serious hardship now being experienced by many general practitioners in the Service and is seriously prejudicing its success."

Several speakers urged that the betterment factor should be 85%, thus tying it to the expert's estimate of the increase cost of living for the professional and middle classes. The Meeting, however, was evidently convinced by the arguments put against this by other speakers, not the least of which was that the medical profession should not expect immunity from the consequences of the country's present financial position. The amendment to press for a betterment factor of 85% was lost by a large majority.

There was again discussion on how the increase to the Pool should be distributed, and the S.R.M. finally accepted the recommendation that it should be used to increase the capitation fee of the first 1,000 on a doctor's list. More was heard about the question of restricting the numbers on a doctor's list below the present maximum of 4,000. In a discussion on this the Meeting was once more brought up again the fact that the limitation of a list to, say, between 2,000 and 3,000 would interfere with the free choice of doctor to patients; once this interference is made, a first step will be taken towards the introduction of a whole-time salaried service. Several rural practitioners enlivened the debate with vigorous first-hand accounts of their own experiences, and made it clear why there has not been more overt approval of the Association's success in obtaining half a million pounds of new money for the Mileage Fund. It seems, though this has not sufficiently relieved the position of many practitioners in rural areas; at the same time, if the betterment factor now being asked for is obtained and applied to the first 1,000 on a doctor's list, rural practitioners should be among the first to benefit, as from the nature of their work the numbers of patients on their list cannot be large.

Although the Meeting had to go over the same ground already covered by the General Medical Services Committee and the Conference of Local Medical Committees, new facts were brought to light, fresh emphasis was given to familiar aspects of the same problem, and, what is perhaps more important, the S.R.M. with representatives from all branches of the profession gave its solid backing to the case already made by the G.M.S. Committee on behalf of general practitioners working in the National Health Service. It is to be hoped that the Minister of Health will not delay much longer in making known to the medical profession his decision, and that of the Treasury, on the betterment factor to be applied to the remuneration of general practitioners.

TEMPORAL ARTERITIS

In 1890 Jonathan Hutchinson¹ described the case of a man of 80, father of a London Hospital beadle, who found wearing his hat painful. Painful and swollen temporal arteries accounted for his symptoms, which in due course disappeared. Forty years passed before Schmidt² described a similar case; and in 1932 workers at the Mayo Clinic, unaware of previous cases, described the apparently new disease "temporal arteritis." This disease has recently been the subject of two critical reviews, one by Harrison³ in this country, and the other by Protas and Saidman⁴ in the U.S.A. The British author has discovered 75 cases in the literature compared with the Americans' 34. The number of recorded cases is probably mounting rapidly; neither of the papers referred to includes the four cases recently reported by Jennings⁵ in this *Journal*. The disease is obviously rare, though, since it was not properly recognized until 1932, it has only a few years' history. Cases in the U.S.A. and Great Britain comprise the recorded majority; there have been, however, reports from the European continent. It is, like many another rare condition, a disorder which accumulates around medical teaching centres. In certain respects it is a clear-cut entity: it is a disease of senility in both sexes, for nearly all the cases are aged 60 or over; it runs a six months' course; all the cranial arteries may be affected, and indeed many large arteries elsewhere in the body; blindness due to retinal ischaemia from involvement of vessels behind the globe is found in one-third of the cases; and death from cerebral haemorrhage often occurs. The histological appearances are typical: the medial arterial coat is infiltrated with lymphocytes, plasma cells, and, outstandingly, giant cells, from which one name of the disorder is derived.

The questions which might reasonably be asked about this condition include whether it is really a separate entity, how it differs from polyarteritis nodosa, and whether it has been correlated with rheumatic conditions (some patients with temporal arteritis have been arthritic, but at their age, they might well be). It would also be relevant to inquire what comprises a clinical entity. A syndrome has been defined as a disorder with three symptoms and not less than three recorded cases; and temporal arteritis fully satisfies these criteria. But there is little to show that it is not polyarteritis in an older age group. Classical polyarteritis is a disease of men more than of women, and the age of the patients is usually between 25 and 45.

Eosinophilia and albuminuria are often present, and neither is seen in temporal arteritis. Finally, the histology differs, as does the prognosis: the majority of patients with polyarteritis die. Jennings considers that temporal arteritis is part of a generalized arteritis in old people, and experienced histologists to-day recognize widespread arterial disease, affecting arteries of medium size and arterioles, far more frequently than in the past. Many allergic conditions fall in this group, and it would be premature to accept "temporal arteritis" with certainty as a distinct entity, though it has passed the acid tests of being described by a British physician, being forgotten, and being redescribed and annotated in the U.S.A.

HORMONES AND ENZYMES

Underlying the physiological changes brought about by hormones are biochemical changes, and the mode of action of hormones will remain obscure until more is known about how they modify biochemical processes. Some recent experiments have shown that the amount of an enzyme called by Mendel pseudocholinesterase in different tissues is altered by the action of hormones. If this enzyme plays some part in ordinary metabolism the amount present would be expected to be the same in both sexes, but in 1940 Birkhäuser and Zeller¹ showed that the livers of female rats contained three to five times more than the livers of male rats. Pseudocholinesterase differs from the cholinesterase present in the central nervous system, which is known as true cholinesterase and which is almost certainly concerned with the hydrolysis of acetylcholine. Though pseudocholinesterase is able to hydrolyse acetylcholine, this is not likely to be its function, which still remains undiscovered.

Poisoning with carbon tetrachloride reduces the amount of pseudocholinesterase in the livers of rats, and similarly in liver diseases the amount is low. The enzyme is also present in serum or plasma, and there it is associated with the albumin. Administration of oestrogens augments both serum cholinesterase and serum albumin. From these several observations it seems clear that pseudocholinesterase is produced in the liver² and is present in the blood. Sawyer and Everett³ have shown that after castration the plasma pseudocholinesterase in the female rat falls to 40% of its initial value, while in the male it rises to 50% above its initial value. When pellets of oestradiol are implanted in the female the amount of pseudocholinesterase in the plasma is trebled, and when testosterone is injected into male rats the amount is halved. Recently Hawkins, Nishikawara, and Mendel⁴ have shown that after thyroidectomy the amount of pseudocholinesterase in the plasma of rats rises from a normal value of 41 to 97. If thiouracil (which prevents the formation of thyroxine by the thyroid gland) is given to rats the pseudocholinesterase value rises to 117. On the other hand, when healthy rats are given thyroxine the pseudocholinesterase value falls below normal to 28. No similar changes were found in true cholinesterase values in any of these experiments. The biochemical process in which pseudocholinesterase takes part must be one which is greatly augmented or reduced in intensity by the circulating hormones, and the interesting observations already made will stimulate further search for the function of this enzyme. The conception that hormones act at least in part by modifying the production of enzymes in the liver is a new one, and further examples of this action are likely to be heard of soon.

TUBERCULOUS MENINGITIS TREATED WITH STREPTOMYCIN

Experience in Scotland

The interim report of the Streptomycin Subcommittee* of the Scottish Scientific Advisory Committee describes how 81 cases of tuberculous meningitis were treated at the five Scottish streptomycin centres between September, 1947, and May 31, 1948. The results of treatment were assessed after a minimum survival period of four months (122 days) from the date of admission. The diagnosis of tuberculous meningitis was confirmed by isolation of the tubercle bacillus from the cerebrospinal fluid in 77 cases, in 75 of them during life and in two at necropsy. The remaining four cases, not bacteriologically proved, have been included in view of the very strong presumptive evidence of the disease. The series includes a number of patients who developed clinical signs of meningitis while undergoing streptomycin treatment for miliary tuberculosis. Such an occurrence might indicate that a "silent" involvement of the meninges had been part of the original miliary spread.

Results of Treatment after a Minimum of Four Months' Observation and Treatment in those who Survived

Age on Admission	Total Admissions up to May 31, 1948	Condition on Sept. 30, 1948		
		Dead	Stationary Relapsed Deteriorating	Progressing Favourably
Under 4 years ..	21 (100%)	13 (62%)	3 (14%)	5 (24%)
4-17 years ..	36 (100%)	14 (39%)	1 (3%)	21 (58%)
Over 17 years ..	24 (100%)	18 (75%)	1 (4%)	5 (21%)
Total ..	81 (100%)	45 (56%)	5 (6%)	31 (38%)

The following classification was used in assessing the clinical state: *Early*.—Minimal physical signs; no neurological signs; not badly confused. *Intermediate*.—Definite meningeal and neurological signs present; confused but able to be roused. *Late*.—In coma; many neurological signs.

Results According to Clinical Condition on Admission

Clinical Condition on Admission	Total Admissions up to May 31, 1948	Condition on Sept. 30, 1948		
		Dead	Stationary Relapsed Deteriorating	Progressing Favourably
Early ..	21 (100%)	7 (33%)	3 (14%)	11 (53%)
Intermediate ..	44 (100%)	24 (54%)	2 (5%)	18 (41%)
Late ..	16 (100%)	14 (88%)	0	2 (12%)
Total ..	81 (100%)	45 (56%)	5 (6%)	31 (38%)

Treatment

In this series no case of meningitis responded for any length of time to intramuscular streptomycin alone, and in common with other workers it was agreed that all cases require streptomycin by both the intramuscular and the intrathecal routes.

Intramuscular Therapy.—The daily dose of streptomycin used intramuscularly was 1.5 to 2.0 g. for adults and 20 mg. per pound body weight for infants and children. At the beginning of the trial this amount was given in four doses at six-hourly intervals, but later the interval was lengthened to 12 hours. This lengthened interval seemed to be equally effective, since at the end of 12 hours the blood level of streptomycin was generally above 0.5 µg. per 100 ml., which was regarded as adequate. Intramuscular injections were usually continued for a period of three months and sometimes longer.

Intrathecal Therapy.—The scheme of dosage for intrathecal streptomycin varied more than that for intramuscular therapy. The one most frequently used was a daily intrathecal injection of 100 mg. for two or three weeks. This was given continuously or on alternate weeks with a rest period intervening; in other cases injections were given on alternate days. For children under the age of 12 the dose was sometimes reduced to 50 mg. and for those under the age

*Professor D. M. Dunlop was chairman of this committee, and the other members were Professors J. W. S. Blacklock, C. Cameron, S. Graham, and G. L. Montgomery, with Drs. T. Anderson, D. Bell, D. G. McIntosh, and J. D. Ross. Dr. I. M. Macgregor was medical secretary and Mr. G. Robertson secretary.

of 3 years to 25 mg. At the end of the initial intensive therapy streptomycin was injected into the theca whenever the cerebrospinal fluid was removed for examination. This was usually done once a week for several months.

The toxic signs observed, roughly in order of their frequency, were fever, vertigo, rashes, vomiting, deafness, and nephritis. The minimum period of observation was seven months in 52 of these patients; 20 (38%) have survived, and 17 (33%) of them are progressing favourably.

The report concludes by pointing out that the results at present are impressive for a disease which formerly was universally fatal, but final conclusions in regard to the real rate of cure must await an extended period of observation.

MENTAL HEALTH WORKERS IN CONFERENCE

FIRST EXPERIENCES OF NEW LEGISLATION

A conference on mental health was held on March 17 and 18 in London and attended by delegates from local health and education authorities in all parts of the country and by representatives of voluntary agencies. The summoning body was the National Association for Mental Health, whose patron, the Duchess of Kent, formally opened the conference, at which first experiences of the recent social legislation and its implications for mental health were discussed.

Sir WILSON JAMESON, Chief Medical Officer of the Ministries of Health and Education, in an introductory address, spoke of the continuing value of voluntary organizations, able and willing to experiment and to indicate ways in which the official services could profitably develop. He begged mental health workers to address themselves to measures which seemed likely to cut down admissions to hospitals or to shorten stay. He looked forward to a closer liaison and interchange of staff between general and mental hospitals.

Dr. J. R. REES, who was president of the International Congress on Mental Health held last August, said that recommendations formulated by the Congress had been sent to the appropriate United Nations agencies, especially the World Health Organization, whose executive at its recent meeting had adopted a very large number of them and was proposing a considerable budget—about a million dollars—for mental health work next year. These recommendations had to be endorsed by the World Health Assembly to be held in Rome in June. This progress was the more noteworthy because a large proportion of the members of the executive of WHO were public health men, and this was the first occasion on which, in international public health work at any rate, more than lip service had been paid to mental health.

The State and the Individual

The discussion on the effect in particular of the National Health Service Act was opened by Professor D. R. MACCALMAN, Nuffield Professor of Psychiatry in the University of Leeds. The official attitude towards mental health, he said, was still over-anxious about care and control, especially the control of persons of unsound mind. Clinics for the treatment of neurosis were too much burdened with minimizing the nuisance factor to society of the maladjusted, and child guidance was most frequently concerned with behaviour problems, many of which could have been prevented by reasonably good upbringing and imaginative education. As one who had approached the National Health Service Act with caution and even scepticism, he acknowledged that the more he had seen of its working—as a member of a regional hospital board and for a short time as a member of an advisory committee in another region—the more gratitude and admiration he felt for its architects. The danger was that the Act might be so interpreted and administered that emphasis would be placed here again on methods of care and treatment rather than on the investigation of fundamental causes. For research under the National Health Service "money should be poured out like water." It was the one field in which they should never economize. He also stressed the harm which might result from

the State doing too much for the individual. The child whose parents lavished on him anxious and indulgent care grew up unattractive and unbalanced in character, and there was some anger of a too benevolent and over-protective Government vitalizing its citizens.

These remarks brought to the platform Dr. H. B. MORGAN, I.P., who said that in former days too much was done for certain spoiled citizens in privileged positions in order that they might acquire wealth at the expense of the community. He object of the Health Act and the National Assistance and Insurance Acts was to set up a standard below which the ordinary citizen should not be allowed to fall.

Dr. R. SESSIONS HODGE said that the research for which Professor MacCalman had pleaded was not necessarily a question of big battalions; some of the best research work had been done by individuals and small units. He suggested a system of clinical assistantships whereby men in general practice who had the right temperament and personality might do their local areas work in association with those engaged in psychiatry. Dr. J. STEVENSON LOGAN deplored the attitude of some sections of the medical profession towards institutionalism. They did not fully apprehend what the mental hospitals could now offer, and were not disposed to play their part in securing mental hospital treatment for their patients.

Psychiatric Social Workers

Miss MARJORIE BROWN, psychiatric social worker in the department of Psychological Medicine, University of Durham, said that psychiatric social workers now numbered 330. About one-third worked in mental and general hospitals and clinics, one-third in child-guidance services, and one-third in other forms of mental health work. About 50 students were trained each year. She thought that local health authority psychiatric out-patient clinics, which were points of contact between the regional board and the local health authority, should be a decisive force in the mental hygiene of the future. Only a few of these clinics had been established so far, and there were a large number of unfilled posts, most of them in adult work—a number which, owing to the demands of the Act, was increasing. The shortage was partly due to the general lack of social workers, but also to competition with other more attractive forms of social work and training courses.

Dr. WYNDHAM DAVIES mentioned the difficulty in obtaining mental health staff, particularly in counties like Cornwall. They were now reduced to bargaining for candidates and had to compete with the demands for social workers in other fields. Even worse, the National Association for Mental Health had had to close down some of its regional organizations which had been of very great value in recent years. (It was explained that this closing down of the National Association's activities was in no way a voluntary withdrawal, and that the Association had protested and pleaded in vain against such closure.) The result was that those at the periphery were left to their own resources. Voluntary associations, of course, were pioneer bodies and sooner or later must withdraw from the scene, but it is time for their withdrawal was not yet.

Many good points were made by lay speakers in this discussion. One parent referred rather resentfully to the health worker who, after her week-end leave—parents did not get week-end leave—called on Monday morning at the home and talked in a rather superior way to the overburdened mother. His speaker suggested the recruitment of social workers from postgraduate mothers—"mothers whose children were off their hands, and who could get down to 'kitchen-sink level' with the women they visited.

Art of Consultation

The second day of the Conference was devoted to a widely ranging discussion on the need for understanding of the individual as part of the training and function of doctors, nurses, and teachers. Professor J. C. SPENCE, Professor of Child Health, University of Durham, said that the doctor needed to have a basic, expert, and specialized understanding of the individual if he was to work with success.

"The real work of a doctor is only faintly realized by many lay people, and I am more disposed to say this now that we see how

ill designed are some of the plans for its conduct. It is not an affair of health centres or public clinics or operating-theatres or hospital beds. These techniques have their place in medicine, but they are not medicine. The essential unit of medical practice is the occasion when, in the intimacy of the consulting-room or sick-room, a person who is ill, or believes himself to be ill, seeks the advice of a doctor whom he trusts. This is a consultation, and all else in the practice of medicine derives from it. The purpose of a consultation is that the doctor, having gathered his evidence, shall give explanation and advice. . . . The explanation is pursued further with what the Greeks call *pronoia*, which is something more than prognosis. It is knowing all about a person without being told. With this, the doctor uses his understanding of the individual and of his disease to prepare him and his near relatives for the hospital, for the technical treatment in the hospital, and for his life after hospital. It is not difficult to realize something of the intimacy, the courtesy, and the understanding which are required in this work."

Some doctors, Professor Spence continued, did not like this way of medicine. They were more interested in things than in people, and would find their places in the laboratory field or in technical therapeutics. The art of consultation was best practised in out-patient departments. In his own hospital consultations were given by the most experienced members of the staff. Two or three students were allowed to watch and listen with as much self-effacement as possible. The students were told that before explanation and advice could be given to a patient they must make three diagnoses—namely, of the disease, of the concept of the disease in the mind of the patient, and of the patient's capacity to understand the explanation and follow the advice. With this preliminary explanation students were quick to see the significance of consultation, and some of them confessed that through these experiences they realized for the first time what the practice of medicine meant.

Professor BRIAN STANLEY, Director of the Institute of Education, University of Durham, followed on the same lines from the point of view of the teacher, and Miss MAY IRVINE, tutor for psychiatric social work at Manchester University, from that of the social worker. Miss OPIE, of King's College Hospital, remarked that in spite of the shortcomings of the nursing profession they did try hard in their educational system to lay emphasis on the importance of the individual. In two big London hospitals at any rate the nurses were told to give welcome and reassurance. Nurses found that it was easy to be patient with the patient, but less easy with the patient's relatives.

Dr. SAWLE THOMAS, speaking as psychiatrist to a regional board, pleaded for an understanding of the doctor by those who were responsible for hospital administration. Most, if not all, doctors who had achieved positions in administration had graduated through years of clinical work, and might be expected to have sympathy and respect for the clinician; but this was not always evident, because the doctor who went in for administration was perhaps overweighted on the side of tidiness, or, it might be, had surrendered to the temptations attached to a position of authority. In some of the mental hospitals under the old dispensation the staffs were so frustrated that all initiative was killed. Autocratic local authorities, too, had failed to allow for freedom in carrying out new ideas. In working with the National Health Service, however, his experience was that these dangers had been avoided. The regional hospital board had delegated its power to management committees, and they in their turn to house and advisory committees, and in this way all groups had an opportunity of expressing their views and putting forward plans which were assured of sympathetic consideration.

Child Care

Much was heard during the Conference on the subject of child care. Miss P. ARMSTRONG, children's officer of the East Suffolk County Council, spoke of some of the difficulties in obtaining foster-homes, and startled the assembly with her description of some dubious private schools catering for parents (her script said of the wealthy classes, but in reading it she altered it to the middle classes) who desired to conceal and be relieved of their unwanted children. Dr. LESLIE HOUSDEN referred to the increase in juvenile delinquency, and suggested that it was impossible to change the mental attitude of parents on a scale wide enough to affect the sum total of mental

ill-health in the country, and that the only practicable step was to concentrate on the younger generation. Dr. C. O. STALLYBRASS spoke of the need for the nurture and protection of home life. Unhappy marriages brought a heavy penalty to the partners, but a heavier penalty to the children.

Finally, Dr. T. C. GRAVES mentioned the physical factor in mental illness. He described the case of a schoolboy aged 16 whose mental disturbance was at first ascribed to over-study, but afterwards he was diagnosed as a schizophrenic and treated accordingly. Eventually on physical examination he was found to have infective conditions of the nose and throat, with gross impaction of wisdom teeth. Within a month of these conditions being attended to he had recovered, and his recovery had been sustained over a period of fifteen years. Dr. Graves pleaded strongly for an integrated medicine.

The chairmen at the successive sessions were the Rt. Hon. R. A. BUTLER, M.P., Professor A. N. SHIMMIN, of the University of Leeds, and Dr. G. B. JEFFERY, director of the University of London Institute of Education.

SOCIAL MEDICINE

Rockefeller Foundation Director's Address

Dr. John B. Grant, the Director for Europe of the International Health Division, Rockefeller Foundation, addressed the annual meeting of the Institute of Almoners on March 25. The chair was taken by Professor Alan Moncrieff.

Medicine in all western countries, said Dr. Grant, was moving from the individual to the family as the unit. In a sense men like Pasteur and Koch had retarded medical development for half a century by increasing interest in the minutiae of scientific medicine. Only now were we emerging into the broader conception. Social welfare legislation was a comparatively new thing. The first country to introduce family allowances was Belgium in 1930, and in the succeeding 20 years 30 countries had legislated in that direction. Two forces had been responsible for the new pattern of health and social welfare legislation—political forces and advances in scientific knowledge.

Five non-medical measures were necessary for providing adequate health care: (1) legislation for social welfare other than medical care, with particular reference to family allowances, training of the disabled, maternity benefit, and home helps; (2) a housing policy based on population needs rather than rental values; (3) a national food policy; (4) provision for mental, social, and physical recreation through community centres; and (5) educational measures for the development of "health-consciousness." To these must be added three medical measures: (1) removal of economic barriers to health care; (2) provision of sufficient health personnel properly distributed; and (3) a high degree of technical excellence in both personnel and equipment.

The eventual quality of health care in any community, Dr. Grant went on, would be determined at the level of the health community centre—not at the hospital. He did not think it was enough to have a health centre as projected in the British National Health Service. It must be tied up with a community centre. Unfortunately health centres had not reached a satisfactory stage experimentally anywhere in the world. The first country to investigate what a health centre might be was Great Britain—in the report of the late Lord Dawson of Penn, published in 1920. He believed that that report would increasingly be the corner-stone of all health services, whether in England, the United States, or Soviet Russia; yet in 1949 there was not one example of such a health centre in England.

The rapid development of medical technology had brought into existence an army of what he called "para-medical workers." Legislation would not provide adequate medical care until these para-medical workers were available in sufficient numbers and their training and supervision were well organized. He travelled all over the world in 1945-7 and found every country bringing out White Papers, but the only country he went to where anybody had got down to the subject and said, "Maybe we will require such and such a number of workers," was Australia.

Group Practice

Dr. Grant believed that in future the medical practitioner would find it increasingly to his advantage to practise in group at a centre where he would be provided with all necessary tools. At present the general practitioner concentrated on the relief of pain and the re-establishment of organ function. His responsibility in the future would be to establish the functional capacity of the patient in expectation of his return to his community as a socially useful person. The family rather than the individual would be the unit of practice. There would be unification of health care in a continuous programme from cradle to grave. Teams would be captained by the general practitioner and supported where required by specialists and institutional facilities. The team would be responsible not only for diagnosis and treatment but for the provision of measures for the protection of the individual and the family against forces which interfered with maintenance and development of full mental and physical capacity. Social medicine in the sense in which it was known in England was one hundred years old. Virchow and others in Germany nearly a century ago were doing what Professor Ryle was now doing in this country. The pattern of health services was already clear. Economic barriers to medical care would be removed by insurance or taxation. Distribution of care would be increasingly improved through institutions in regional areas based as far as possible on teaching hospitals integrated with non-teaching hospitals and health centres.

In conclusion Dr. Grant said that a satisfactory level of practice of social medicine would depend to a very large degree upon the availability of adequate numbers of well-trained medical and psychiatric social workers. The immediate problem was to define the relationship of the social worker to other workers in the team providing health care from health community centres.

THE KING'S HEALTH

Long Convalescence

The following bulletin was issued on March 30 from Buckingham Palace:

The King continues to make good progress after his recent operation. In order to secure the continuation of the natural process of formation of collateral circulation which has been encouraged by the operation, we have advised His Majesty that a prolonged period of convalescence will be necessary.

MAURICE CASSIDY.	J. R. LEARMONTH.
THOMAS DUNHILL.	J. PATERSON ROSS.
HORACE EVANS.	JOHN WEIR.

It is understood that this will be the last bulletin to be issued for the time being. Others will be issued should occasion arise but not regularly.

A. CANTERBURY COMMEMORATION

On the afternoon of June 25, the first day of the Canterbury Festival, there is to be a service at the cathedral which will take the form of a commemoration of the science and art of healing. The Dean of Canterbury, Dr. Hewlett Johnson, who presided over a meeting in London at which the arrangements for the commemoration were discussed, explained that the occasion was intended to be not diocesan but national, and indeed world-wide, for representatives of medical services in other countries would be invited to attend. One whom he very much desired to see present would be Dr. Albert Schweitzer. So much was owing to the medical services in every land that the Friends of Canterbury Cathedral wanted to make the service as representative as possible of all branches of medicine and nursing and the sciences allied to them. It was hoped that the procession would include representatives of the Royal Colleges, the universities, and all the services and organizations, such as the British Red Cross and Order of St. John, concerned with the art of healing. Miss Margaret Babington, who is the honorary manager of the Festival, said that the late Archbishop

Lang had left a legacy to the Friends of Canterbury Cathedral to be used for music and furnishings, and it was proposed to ask a well-known musician to compose an anthem for the service. It was hoped that an eminent medical man would read the lesson and another deliver the address. After the service there would be a performance in the chapter-house of Miss Dorothy Sayers's play, "The Zeal of Thy House."

TREATMENT OF BREAST CANCER

American Experience

Dr. FRANK ADAIR, of the Memorial Hospital, New York, lectured to the Section of Surgery, Royal Society of Medicine, on March 23 on "Surgery, Radiation, and Hormones in the Treatment of Breast Cancer." He began with an acknowledgment of the value of British work in cancer research.

Experience had shown, said Dr. Adair, that to give a sufficient dose of x rays to kill breast cancer, using x rays only, was not feasible, owing to the great damage caused to the skin and other tissues. In his work, therefore, x rays had come to be used only in inoperable cases. He criticized the employment of radiation to cover inadequate surgery. The value of pre-operative x-ray therapy was still in doubt and the results were not easy to assess; there was less doubt about the value of post-operative irradiation. At the Memorial Hospital patients in whom no involvement of the axillary glands could be detected microscopically were treated by surgery alone; when there was such involvement post-operative x-ray therapy was undertaken.

The proportion of five-year survivals after radical mastectomy, when the cancer was limited to the breast, was 74% during the period 1934-9 at the Memorial Hospital. During the period 1940-4 it was 82% and there was a corresponding increase in "cures"—cases in which there was no trace of cancer after five years. It was difficult to estimate the value of post-operative irradiation, but he thought it might add 3 to 5% to the survival figure. For any such assessment, of course, they had to depend upon comparisons between different clinics, where the techniques might not be identical.

Turning to hormone therapy, Dr. Adair, after a reference to the work of British investigators on the oestrogens, referred to a study arranged in America by a subcommittee of the Therapeutic Trials Committee. Supplies of androgen and oestrogen had been distributed to about twenty groups of workers who reported periodically. In his own practice he had been much impressed by the occasional response to the injection of testosterone, particularly in cases where there were metastases in bone. Cases of breast cancer treated with testosterone ceased to menstruate for from three to six months, and in those women near the menopause this amenorrhoea might be permanent. Of 21 cases with metastases in bone, 15 showed a significant drop in serum calcium during the first three months' treatment with testosterone. Cases in which there were secondaries in the liver, with jaundice, had cleared up temporarily under testosterone therapy. Large doses of testosterone induced male characteristics, and in that way possibly inhibited further mammary growth. The dosage of testosterone was 100 mg. three times a week, given over an indefinite period. Here he noted that the age ranges of patients who came up for treatment for breast cancer showed two peaks, one at about 45 as the menopause was approached, and the other at about 60, when there began to be no hormones present at all.

A "hormone team" had been organized at his hospital, including clinicians, a chemist and a biochemist, a radiologist, a full-time nurse, and a full-time social worker. The most satisfactory oestrogen was found to be stilboestrol. Under the microscope there appeared to be no difference between mammary cancer destroyed by oestrogens and that destroyed by irradiation. In some cases undergoing prolonged oestrogen therapy no indication of cancer remained. Their experience with oestrogen, however, had not been as striking as with testosterone. Oestrogen therapy in some cases required months before improvement took place. He looked

forward to the introduction of new chemical substances having the same beneficial effect as the hormones now in use but without the distressing features which sometimes accompanied them. There were approximately 600 chemical compounds which should be investigated, and the chemists and the endocrinologists must take the lead in this investigation. He believed that the life history of breast cancer had already been profoundly modified and that a further great contribution might be made during the next few years.

There was no discussion following the address, but Sir STANFORD CADE voiced the thanks of the Section.

ABDOMINAL EMERGENCIES

A meeting of the Liverpool Medical Institution was held on Feb. 3, with the president, Professor CHARLES WELLS, in the chair.

Mr. W. M. BEATTIE read a paper on a consecutive series of 598 emergency abdominal operations, performed at Smithdown Road Hospital by five surgeons during a period of two years. The total mortality was 10.7%. In 347 cases of acute appendicitis the mortality was 2.3% (0.3% in unperforated and 7.6% in perforated cases). Diagnostic mistakes were discussed, and it was pointed out how often patients who had pain in the right iliac fossa only had a normal appendix at operation. The mortality of 19% in 67 cases of perforated peptic ulcer was analysed, and the well-known unfavourable factors of advanced age, delay in operation, associated haematemesis, and a deranged mental state were stressed. Other figures showed that strangulated hernia was a hazard of old age, 60% of the 75 cases occurring in patients over the age of 60 and 35% in patients over the age of 70.

The number of cases of cholecystitis was limited because treatment was conservative whenever possible; the mortality in those who required immediate operation was 62.5%, and the average age of the fatal cases was 75. Three cases of pancreatitis and 8 cases of perforated diverticulitis were also described. At the same meeting Mr. A. McKIE REID read a short paper on some recent advances in ophthalmology.

Preparations and Appliances

DIATHERMY PRONG FORCEPS

Mr. A. WILFRID ADAMS, M.S., F.R.C.S., writes: This forceps is for use by the surgeon or assistant to seal vessels in subcutaneous and parietal tissues. In the depths, too, thanks to its length, it replaces ligatures of minor vessels, but is to be used warily near vulnerable viscera. The point of bleeding must be displayed and located exactly and the forceps applied with precision. Being angled, the handle does not block the view of the tip, which is specially small to concentrate and

intensify the coagulating current. The instrument acts vicariously as a tenaculum forceps or aids swabbing in deep recesses.

It is, in the main, a combination of Mollinson's tonsil and Hey's diathermy forceps, and I acknowledge my debt to these inventors as well as to Messrs. Down Bros., who make this new type of haemostat.

Correspondence

Cancer of the Breast

SIR,—Animal experiments show that for carcinoma of the breast to develop in the mouse it is necessary that suckling should have taken place from a mother or foster-mother capable of transmitting a virus-like material known as the milk factor. If mice are not so suckled carcinoma of the breast does not develop.

I am anxious to start a long term—very long term—investigation into this matter in the human subject, and for this purpose I wish to collect the names and addresses of female children or adults of whom it is known that they have never suckled at a human breast. Family doctors and obstetricians may know of such cases where, because of the death of the mother or for other reasons, it can be *absolutely guaranteed* that the child has never consumed milk from a human source. ("Humanized milk" does not, of course, count.) If, with the permission of the appropriate person, doctors would be kind enough to forward the name, age, and address of such a child or adult, together with the name of her surviving parent or guardian in the case of a child, such an investigation could be put into operation. The card or letter should be addressed to the Secretary of the Mastitis Clinic, Guy's Hospital, London, S.E.1. It is hoped by this means to collect the names and addresses of a large series of females who could not have received the human "milk factor," if such exists, and the investigation would proceed as follows.

On receipt of the name, the child's parent or guardian would receive the following letter:

"Dear ———,
"Dr. ——— has, with your permission, sent me the name of ——— who, he assures me, has not been nursed by her mother or by a foster-mother. Doctors believe now that such children, when they grow up, may be less likely to develop serious disease of the breast than other people, and this possibility you might regard as making up for the lack of what is otherwise the best method of nursing a baby. Nevertheless it is vitally important that this theory should be tested out, and I should be most grateful to you for your co-operation, which might in the future save many lives. All that I shall do is to send you once a year a stamped addressed post-card asking you whether there has been a change of address or whether ——— has now left home. When she grows up and leaves home I or my successor will keep in touch with her in this way, and after explaining to her that we believe that she is less likely to suffer from serious breast disease than her friends, ask her whether she will reply year by year on an addressed card as to whether she is still free—as we expect—from any trouble in the breast. It is perhaps only by finding out these things, which as you will appreciate is bound to take many years, that the problem of cancer will eventually be solved.

"If, when ——— grows up, she does not wish to co-operate in this matter she can either ignore the post-card, which, after two years without a reply, will not be sent again, or she can write and tell us not to send her any more, but I hope that she, like you, will feel that by helping in this matter she is really doing her bit, and at such small cost, to alleviate human suffering and advance knowledge.

"Signed ———."

A letter in similar vein, and with appropriate modifications, will be sent to adults.

I, Sir, can see no other way in which this matter, vital to the welfare of the human race, can be settled. That the results of this experiment cannot be seen by anyone reading these lines makes it all the more important that we should start now, and be sure of answering at least one fundamental question about human breast cancer by the year 2030.—I am, etc.,

H. J. B. ATKINS,
London, S.E.1. Director of Surgery, Guy's Hospital.

Diabetic Coma

SIR,—In your issue of April 2 (p. 565) Drs. Lee, Naidoo, and Torrens compare the treatment of diabetic coma with and without the early administration of glucose, and conclude that treatment with glucose significantly increases the mortality. I cannot agree that their data warrant this conclusion. True, the gross mortality in the group of glucose-treated cases is 40% and in the group of saline-treated cases 11%; but the

two groups are not comparable, and when similar cases are abstracted from each group and compared the difference disappears.

It is generally agreed that the prognosis in diabetic coma becomes worse with increasing age of the patient, with increasing depression of the alkali reserve, and with increasing fall of the blood pressure. In the group of glucose-treated patients, 3 of the 10 cases are over 50 years of age; in the group of saline-treated only 2 out of 18. The average age of the fat cases in the glucose group is 51 years; in the saline group 32 years. If we exclude the patients over 50 years of age, is found that the mortality rates in the two groups are the same.

The average value for the alkali reserve on admission of the patients who died in the glucose-treated group is 9.8 vol. CC per 100 ml.; in the saline group 12 vol. per 100 ml. The average value for those who recovered in both groups is 14.8 vol. per 100 ml. In each group there were four patients whose systolic blood pressure on admission was under 100 mm. Hg and of these one died in each group. In my opinion, therefore, the data provided show no difference between the results of the two treatments.

Nevertheless we should all agree that the results of treatment of diabetic coma, particularly in the elderly, provide no grounds for complacency. That derangements of water and electrolyte metabolism and circulatory collapse are at least potent factors in such deaths is generally recognized, and if any method of treatment can be shown to contribute to these it should be carefully examined from this point of view. It is known that in dehydration much potassium and phosphorus is lost from the body, that these are derived from the cells, and that with their loss intracellular dehydration occurs. When sugar is being removed from the blood either under the influence of extra glucose or insulin—and *a fortiori* when the two influences are combined—a rapid fall of the plasma potassium and phosphorus occurs, and this in depleted patients may lead to serious symptoms. The extent and potential seriousness of potassium and phosphorus deficits and associated disturbances in diabetic coma have been the subject of a recent investigation by Butler *et al.* (*Trans. Ass. Amer. Phys.*, 1947, 60, 102). If these views are correct, then the rapid correction of the disordered carbohydrate metabolism in diabetic coma may precipitate acute disturbances in the electrolyte balance of a body already depleted. It is perhaps significant that it is only in respect of severe and advanced cases of dehydration in diabetic coma that any suggestion has been made that glucose may have a deleterious influence. But the remedy for this state of affairs is not to abandon a potent weapon—glucose—for the correction of the disordered carbohydrate metabolism, but, as indicated by Butler, to provide the surprisingly large amounts of potassium, phosphorus, and other electrolytes required to remedy the depletion of these substances.—I am, etc.,

London, W.C.1.

H. P. HIMSWORTH.

Height of Hospital Beds

SIR,—As the hospital population grows older, an increasing proportion of my patients fall out of bed or while getting out of bed, blackening their eyes or even breaking their bones. Hospital beds are too high and too mobile for safety and they are commonly placed on well-polished floors. Beds are made high to spare the nurses' backs, but it should not be beyond the wit of man to devise a cheap bed which could be raised to table level for making and lowered to divan level for sleeping.—I am, etc.,

Oxford.

L. J. WITTS.

Tumour Agents

SIR,—I write to ask the following questions because of the views expressed by Professor W. E. Gye (March 26, p. 511). Why is he so sure that the agent of the Rous fowl tumour (and other similar tumours) is a particular virus? What are the exact implications of his remarks in the concluding paragraph on the meaning to be attached to the word "virus"? How exactly (and in detail) does he imagine that the "agent" brings into being the sarcoma cell? Is it by virtue of its possessing a "carcinogenic potency"? How does he explain the rigid specificity of type in the tumours produced? How, in view of this specificity, does it come about that the implantation of a mouse carcinoma (presumably caused by a "specific

CROOKES

Lacto-Calamine

PACKINGS

Lacto-Calamine Lotion is supplied in 4 oz. bottles. It is also available in the form of Cream (1 oz. pots) and Talcum Powder (Sprinkler tins).

LACTO-CALAMINE presents high-grade colloidal calamine of exceptional covering and protective power, in a specially evolved lotion base. Semi-emollient, it avoids the drying effect of the ordinary calamine, yet, being non-greasy, it clings without cloying to the normal surface of the skin.

FOR ROUTINE USE, invaluable against sunburn and excessive sunshine and cold, dry winds.

IN THE NURSERY against chafing and for teething rashes.

IN SKIN CONDITIONS from acne to urticaria calling for a mildly stimulating yet soothing application.

A very present help for hypersensitive skins.

THE CROOKES LABORATORIES LIMITED · PARK ROYAL · LONDON · N.W.10

Stimulant action in emergency

Anacardone (Injection of Nikethamide B.D.H.) should be at hand in the surgery and in the doctor's bag ready for immediate use.

Nikethamide B.D.H. exerts a rapid stimulatory effect on the respiratory and vasomotor centres thus raising the depth and rate of respiration and improving the blood supply to the heart in acute collapse.

Anacardone is available in ampoules as Injection of Nikethamide B.P. and as a 25 per cent. solution, flavoured, for oral administration.

terms of TONIC VALUE

First and foremost, Minalex is a children's tonic. It takes the short cut to a child's favour with its delightful orange tang . . . ensures 'patent co-operation' right from the start. Yet Minalex is a tonic in the truest sense of the word. It contains the protective vitamins A and D not just in nominal amounts but in therapeutic doses; it provides iron to aid formation of healthy blood; and, in addition, the glycerophosphates of calcium, potassium, sodium and manganese, together with copper sulphate. N.H.S. prescriptions are revealing more and more preference for Minalex . . . and are showing that doctors realise how the same qualities that commend Minalex for the youthful patient are just as valuable to grown-ups!

An anti-histamine of wide application

HISTOSTAB is one of the most satisfactory antidotes for histamine now available.

In the treatment of a wide range of allergic conditions Histostab has few undesirable side-effects. It may be given orally, or by injection when rapid action is required. It will control allergic urticaria and eczema, and will relieve the itching in certain cases of pruritis. It has proved of value in cases of sensitivity to Insulin, Liver and Penicillin, suppressing the unpleasant effects and allowing treatment to be continued.

As Compound Solution of Histostab it is available for nasal and ocular instillation in vasomotor rhinitis and hay fever.

Histostab Tablets. Bottles of 25 x 0.1 G. tablets.

Injection of Histostab. Boxes of 6 ampoules of 2 ml. (0.1 G.).

Solution of Histostab Compound. Bottles of ½ fl. oz.

The Choice of an Antacid

THE serious disadvantages attending the administration of alkalis in the treatment of the dyspepsias are now well recognized. Recent reports, however, have again confirmed that the use of aluminum hydroxide obviates the secondary rise of acidity and the danger of "alkalosis" which are associated with alkali treatment.

"Alcolac" hydroxide, as a routine in the treatment of patients with hyperchlorhydria, and conditions associated with hyperchlorhydria. "Alcolac" neutralizes excess gastric acidity to the most favourable degree without provoking the danger of "alkalosis," thus producing a markedly soothing effect on the gastric mucosa, with the prompt relief of pain and discomfort.

'Alocol' is available in the form of Powder, Tablet and Cream.

Powder—The normal dose is 1 gramme before and after meals.

Tablets—Each tablet contains Alochol, 0.5 gm.; P. Sacch Alb, 0.4 gm.; Cocoa Powder, 0.035 gm.; Excipient, q.s. The normal dose is 2 tablets before and after meals.

Cream—Formula: Alocol 60 parts approx ;
Glycerin 50 parts ; Ol. Menth Pip 0.005 parts ;
Aq. Chlorof. 40 parts ; Aq. Dest. to 1000 parts
The normal dose is 1 to 3 teaspoonsfuls between
meals and at bed-time.

Complete chemical history of 'Alocol' with convincing clinical reports and supply for trial sent free on request.

Ankylosing Spondylitis

SIR,—I was sorry to see the suggestion put forward by Dr. C. B. Heald (March 26, p. 546) that it is possible to arrest spondylitis deformans by x-ray treatment given early in the course of the disease. I do not believe that this is ever possible, but the patient (if he is already in his thirties when first attacked—an age when the evolution of the condition is usually slow) may have to be kept under observation for several years before recrudescence of symptoms and extension of the physical signs become manifest.

At St. Thomas's Hospital all patients found by me to show clinical signs of subacute sacro-iliac arthritis are treated at once by radiotherapy. This has meant that some cases have completed the course of x-ray treatment at a time when no radiological signs of any disorder were yet discernible. Nevertheless, within one to two years the other sacro-iliac joint was attacked and the typical sclerosis had now appeared on the radiograph of the joint first affected.

It is obviously impossible to start treatment earlier than during the clinical and pre-radiological stage of sacro-iliac invasion. Failure to arrest the disease even in such favourable circumstances shows that x-ray therapy, however effective it proves in abolishing pain (at times for several years), is palliative, not curative.—I am, etc.,

London, W.1.

JAMES CYRIAX.

SIR,—Dr. C. B. Heald (March 26, p. 546) raises several most interesting points. He lays stress on the value of early x-ray examination of the sacro-iliac joints and suggests that more frequent early examination of these joints would lead frequently to a much-needed earlier diagnosis in this condition. This is very true. But apart from radiological diagnosis it is amazing how long such patients can suffer, openly and obviously, from ankylosing spondylitis and still escape the notice of the clinician whose eye is only open to diseases of more popular systems.

The most obvious cases are missed frequently in busy out-patient departments even though the complaint that took that patient to hospital may have been directly due to spondylitis. The following history is by no means unusual.

A man, now aged 56 years, suffered his first symptoms while in the trenches in 1916 at the age of 22. He experienced great pain in the buttocks, the right more than the left, which greatly interfered with his walking. Alternating "sciatic" pains and stiffness and pain in the left shoulder further incapacitated him. He received little sympathy and no treatment. The condition worsening, he was finally discharged from the Army as a man of poor moral fibre. From that time on relapse and remission alternated, though the latter never lasted longer than three months at a time. Any change of weather upset him; usually the cold suited him better than the heat. His spine gradually became flexed, his chest sunken, and his abdomen lax and atonic. Feelings "as though bands were pulling tight round the chest" became a major symptom. At no time were peripheral joints affected. He attended hospital several times and was seen in 1947 in a general medical out-patient department of a teaching hospital, where notes read that he was complaining of tight feelings round the chest, that his chest expansion at nipple level was only 1 in. (2.5 cm.), and that he was suffering from bronchitis and emphysema. On Nov. 30, 1948, 32 years after his first symptoms, the correct diagnosis was first made in a case so obvious that it could have been diagnosed across the Horse Guards Parade.

Such a history is not unusual. But no clinician who will not notice the obvious will bother to order a skiagram of the sacro-iliac joints. Ankylosing spondylitis is a condition that is often just not considered in the differential diagnosis of exertional dyspnoea, transient or persistent backache, alternating sciatic pains, sternal pains and tenderness, or even pyrexia of unknown origin. In our ex-Service patients the average time between onset of symptoms and correct diagnosis is 2 years

11 months; in our civilian cases it is nearer three times that figure. Yet few patients give such typical histories or show such obvious physical signs.—I am, etc.,

London, W.1.

F. DUDLEY HART.

SIR,—The enthusiasm of your correspondent, Dr. C. B. Heald (March 26, p. 546), for the early diagnosis and x-ray treatment of ankylosing spondylitis needs tempering. If he consults the literature of the disease, which comprises some hundreds of papers, he will discover that success was usually claimed in the treatment of early cases before x-ray therapy became popular. He will also find that there is no evidence that deep x-ray therapy arrests the disease, though it does appear to relieve the pain, at least temporarily, in most cases.

That the sacro-iliac joints should be studied for early diagnosis has been advocated for at least twenty years.^{1,2} Buckley³ was the first worker in this country to draw attention to the early changes in the sacro-iliac joints. Dr. Heald refers to "this crippling disease" which affects the "most normal healthy physques." These two ideas were popularized in Gilbert Scott's monograph,⁴ which in my opinion contains many other unsubstantiated statements. Only some 10 to 20% of patients seen in general hospital practice can be described as "cripples," and the disease affects people of most diverse physques.

If we had a cure for the disease and money to spare, Dr. Heald suggested mass miniature radiography of the sacro-iliac joints of young adults might be worth while. As it is, we cannot afford to deal with the far graver matter of pulmonary tuberculosis. Dr. Heald speaks of the x-ray changes being "so diagnostically significant." Personally, in studying large films of the sacro-iliac joints of patients' relatives who have suggestive symptoms (such as the pre-spondylitic thigh pains described by Davies-Colley in 1885⁵), using the radiographs of some 40 normal students as controls, I often find it difficult to decide whether the appearances are significant or not.

Finally, Dr. Heald approves of a skin dose of 2,500 r. I doubt whether one is ever justified in irradiating the sacro-iliac joints of a young woman with such a dose unless harmful effects on the ovaries can be avoided with certainty.—I am, etc.,

Bristol.

Obstetrics in Great Britain and Ireland

SIR,—The statement of Dr. Bethel Solomons (March 26, p. 545) "that from an obstetrical point of view we consider that Great Britain and Ireland are one" is so completely at variance with the facts that I cannot let it pass without the strongest protest. As an ex-assistant-master of the National Maternity Hospital, Dublin, I know that the practice of obstetrics in relation to such matters as (1) so-called therapeutic abortion, (2) craniotomy, and (3) sterilization is the direct contrary to that obtaining in many centres in this country. Convinced as I am from the medical point of view—apart altogether from ethics—that such operations are not necessary in the best interests of patients, I feel that the practice of obstetrics in England would be greatly improved by the adoption of the Irish practice in relation to these various matters. However, the point is that these fundamental differences in the practice of obstetrics in England and Ireland do exist, and no one knows this fact better than Dr. Solomons; therefore his statement quoted at the outset of this letter is misleading and gives a wrong impression of obstetrics as practised in Ireland.—I am, etc.,

Sheffield.

TIM BOLAND.

Fulminating Meningococcal Septicaemia

SIR,—I was interested in the article by Drs. P. Turner and R. V. Dent on fulminating meningococcal septicaemia (March 26, p. 524), more especially because I recorded findings in a series of 173 cases of meningococcal infection occurring in a recruiting depot in East Africa.¹

Owing to the fact that we were dealing with African natives we had to rely upon examination of the conjunctivae for the presence of petechiae. Of the whole series, 78 (45%) presented this sign, many of them before meningism supervened. These latter suffered, as Drs. Turner and Dent describe, from collapse associated with rise of temperature and rapid feeble pulse; a number of them also had loose incontinent stools, which was a bad prognostic sign. Penicillin was not yet available, and I was unaware of the value of adrenal cortical extract, but all cases were immediately put on sulphonamide as a routine. There were 25 deaths (14.5%) in all—21 of the patients dying on the day of admission.

The mortality rate threw some light on the value of petechiae as a prognostic sign. The figures for this series were: total number of cases with petechiae 78, deaths 25 (32%); total number where no petechiae were observed (all verified cases by lumbar puncture) 95, deaths *nil*.

It may be of interest to mention that two cases in the series had persistent meningism with turbid C.S.F. for several weeks. Both cases made uneventful recoveries soon after the intravenous injection of T.A.B. (100 million), followed by a 200-million dose two days later.—I am, etc.,

Kirkby-in-Ashfield, Notts.

Fibrositis

SIR,—Surely Dr. J. H. Young (March 19, p. 499) is right. No one need doubt that Stockman and Steinberg demonstrated small areas of polymorphonuclear infiltration in incised fibrous tissue; also no one doubts that Copeman and Ackerman, when dissecting the lumbar muscles of subjects selected at random, really found fatty lobules there. The question is not, Are these findings factual? but, Are they relevant?

It is futile to examine the myofascial tissues for evidence of the cause of the disorder unless previous clinical examination has shown that the fault lies in those tissues. Since clinical examination on accepted lines shows that patients with conditions called "fibrositis" are in fact suffering from articular disorders, examination of the myofascial tissues is pointless. However many little patches of inflammation or fatty lobules may be found, these must not be thought to represent significant deviations from the normal. Still less can they be regarded as in any way causative of the patient's symptoms. Careful clinical examination must point to the structure at fault, which structure should then be examined for the nature of the lesion.—I am, etc.,

Rickmansworth, Herts

M. C. WOODHOUSE.

Whither Tuberculosis?

SIR,—There have been numerous letters in the *Journal* on this subject, but so far the question of its prevention and control does not appear to have been stressed. The real aim of the profession must be the control and prevention of this foul disease.

About 1930 it was definitely shown in the U.S.A. that tuberculosis of bovine origin could be prevented by the eradication of tuberculosis in cattle and the pasteurization of milk. At that time some 2,000 persons, mainly infants, were killed each year by that form of tuberculosis in this country. If the profession had then insisted on the eradication of tuberculous cattle we should not have to-day some 1,500 deaths each year from this form of tuberculosis. Since 1930 only 16% of our herds have been certified free from tuberculosis. To prevent human tuberculosis of bovine origin we must insist on the complete eradication of tuberculous cattle so that there will be no living germs of tuberculosis in the milk; and then, if it is considered necessary, pasteurize the milk to make it doubly safe.

For the control and prevention of tuberculosis we must know who has been infected and who has so far escaped infection. This is most necessary, as at 20 years of age 80-85% of our population is said to have been infected. The only way to learn the truth about infection is by the tuberculin test, which is reliable in over 95% of persons tested.

Some really effective chemotherapeutic agent must be found that will kill the tubercle bacillus in the human body, and if used as soon as infection has been discovered, and before it has developed into a case of clinical tuberculosis, we shall be nearer our aim of controlling this disease.

Those persons who are still found to be free from infection urgently need protection, and B.C.G. should be made available for these cases. These two methods would save the spending of hundreds of millions on our sanatoria.

The public should be given the following information about our sanatoria: (1) How many beds were available in 1948? (2) How many patients were treated in those beds during 1948. (3) How many of these patients were discharged in 1948 with the disease "arrested." Has any record been kept of the fate of these "arrested" cases after their discharge, and, if so, with what result? (4) Were any patients discharged in 1948 with the disease definitely "cured"? If so, how many have been cured? (5) What was the cost of this sanatorium service in 1948?

The publication of the above facts would show the value of this sanatorium service and raise the question. Can we to-day afford it?—I am, etc.,

Itchingfield, Sussex.

SYDNEY GORDON TIPPETT.

Trilene as an Analgesic in Labour

SIR,—With the recent focus both in Parliament and in the Press on analgesia in childbirth, I think that the lay public should have a note of warning sounded in their ears. The hysteria among the members of committees, both male and female, is almost akin to that aroused by the word "vivisection."

Gas-and-air analgesia is extremely safe, is employed in my unit, and its use taught to midwives. On the other hand, the indiscriminate use of inhalation analgesia with the less safe "trilene" is not unattended by risk. In the last six months I have had cognizance of two maternal deaths in which trilene has been used—in one case as an anaesthetic and in the other as an analgesic.

There has been considerable correspondence recently expressing the view that trilene should be used by midwives in the same way as the Minnitt apparatus. I feel that the findings of the committee who made a recent report for the Royal College of Obstetricians and Gynaecologists should be viewed with considerable respect. These are the deliberations of intelligent and senior men, and, while the gas-and-air apparatus is the safest form of inhalation analgesia, I feel that the indiscriminate use of trilene, both as an analgesic and as an anaesthetic in domiciliary midwifery and minor surgery, should be very seriously investigated.

It is not unknown for practitioners to give one of these self-administering apparatuses to a patient and leave her with it, entirely alone—an extremely dangerous practice. Finally, to stress the danger of trilene, I have knowledge of four cases within the last twelve months in which death has been associated with trilene as an anaesthetic.—I am, etc.,

Irvine, Ayrshire.

RICHARD DE SOLDENHOFF.

Pain in Childbirth

SIR,—I was very interested to read the report of the Medical Women's Federation on "Pain in Childbirth" (*Journal*, Feb. 26, p. 333). As a woman doctor with two small children I have had the interesting experience of having had the first in England in 1946 and the second in 1948 in America, where analgesics in childbirth are more extensively used.

Having given a good deal of time and thought to the problem of muscle control and relaxation I approached my first confinement with an open mind. The labour, however, proved to be excessively painful, and little relief was obtained from either pethidine or nitrous oxide, though "trilene" inhalations did give a measure of relief.

In comparison, the second confinement was a pleasure. Four hours after labour started I had a dose of barbiturates sufficient to cause me to doze almost painlessly through the second and third stages. The infant was born healthy and strong, and

was unaffected by the drugs. I was well and got up two days later.

You suggest that the reactions of the medical mothers may have been abnormal. I do not think so. With their knowledge one would expect them to have a more normal approach to labour than women who have not studied its mechanism. A number of non-medical women have said how painful their labours have been and how little relief has been given.

Let it be recognized that for the majority of women labour is painful, if not an agony, and, unless there be contraindications, the benefits of science should be given to those who wish it.—I am, etc.,

Farnham Royal, Bucks.

MARY HERFORD.

Marriage Neurosis

SIR,—It must be in the experience of other psychotherapists as well as myself to discover in the course of analysis that they are treating the wrong member of a married couple. The one who has been sent for treatment proves to be a more stable and worth-while personality than the one who remains aloof. Such a state of things might well be called the marriage neurosis, although the patient readily falls into the category of one or other of the anxiety states.

I think it worth while to call attention to this, since it is easily overlooked if any short cut in therapy is being attempted. The patient, almost always a woman, is extremely likely to make mental reservations when asked to talk of everything which comes into her head, and, since so much material relevant to her anxiety or guilt complex is produced, it may be easy to take at its face value her assertion that all is well with her marriage. A few illustrative cases will make my meaning clear:

A woman was sent for treatment because she had attempted suicide. Her husband refused to come and discuss the situation, and she took all the blame on herself for domestic incompatibility. A few months later he blatantly paraded another woman, and in many ways showed himself to be almost totally devoid of moral responsibility. In another case the woman had an obsessional fear of harming her children. It became apparent that in addition to the usual determinants she had a husband who, although a "decent chap," was decidedly immature and emotionally a drain on her. Another case was a woman who had been driven all her life by an intolerant super-ego, but who had made adequate adjustments and had a successful career until she married. She then broke down with a guilt complex. Her husband proved non-cooperative, but his history and the story of their married life show him to be victim of a possessive mother and quite unable to accept the responsibilities of a married man.

All these women had in common a very high ideal of what a marriage partnership should be, and their breakdown, though determined by the usual childhood experiences, was precipitated or aggravated by an unwillingness to face the fact that their marriage was proving a failure. Once they were brought to overcome the sense of disloyalty they felt in criticizing their husbands they found relief in facing the realities of the situation. My last illustration is somewhat different:

The woman was sent to me because in five years of married life the marriage had never been consummated. The reason given was her fear both of intercourse and of pregnancy, amounting to a phobia. A very few talks succeeded in clearing this up. Her phobia was based on sexual ignorance and childish fantasies. After three or four talks she left me as eager as any young bride. Nothing happened, however. Her husband still remained aloof, and it proved that all he wanted in marriage was the comfort of a home and a wife who was a substitute for a mother; and he was not prepared to face the disruption of his life which the advent of a child would cause.

Other men can no doubt quote parallel cases from their own practices, but my further reason for calling attention to them is that in three of the cases E.C.T. had been recommended as the appropriate treatment, and one of them actually had a course of ten shocks, with devastating effect to her morale and a worsening of her symptoms. The serious thing is that the advocates of E.C.T. made no attempt to understand the cases, and thus were turning their backs on all we have learned about the origins and meaning of neurosis during the last fifty years. I find myself daily appalled by the cases which come under my notice in which shock therapy has been the first, instead

of the last, resort. In properly selected cases it has value, but used as indiscriminately as appears to be becoming more commonly the case it ceases to be a scientific procedure and is equivalent to "Let's shake the nonsense out of her." When it is seriously suggested, in cases like the above, that after a failure of E.C.T. leucotomy is the next step I begin to despair of psychiatry.—I am, etc.,

Birmingham.

R. MACDONALD LADELL.

Aftercare of the Hospital Patient

SIR,—Dr. J. Greenwood Wilson (March 19, p. 502) tends to adopt the attitude so often displayed by those outside the two professions concerned who discuss what they seem to regard as the rival functions of health visitors and almoners. With regard to the Cardiff scheme for the follow-up of diabetic patients Dr. Wilson says he "would take leave to doubt the ability of almoners anywhere to undertake some important aspects of the work"—i.e., the technical instruction. Almoners themselves would be the first to agree with him. They, however, would not agree that their own specialized training, following the social science course, means that they in any way duplicate the visit of a health visitor "just for social casework." The health visitor and the almoner, in visiting a patient in his or her own home, do so for different reasons, each fundamentally bound up with the separate and complementary functions they seek to perform.

Earlier in the letter Dr. Wilson actually goes right to the root of the matter when he says, "There is no conflict between health visitors and hospital almoners in Cardiff." I submit that in principle there never need be conflict nor overlapping of function. In effect, there very seldom is where members of the two professions are allowed to work together for the good of the patient without third-party interference.—I am, etc.,

London, W.C.1.

M. STEEL.
Secretary, The Institute of Almoners.

Treatment of Varicose Veins

SIR,—Dr. H. M. Hanschell (March 19, p. 500) makes a scathing attack on the use of sclerosants in the treatment of varices. He says that varicose veins left alone carry no mortality, whereas injection with or without ligation may be fatal. "Who dares counter with the sop that varicose veins may become so harsh an affliction of man's estate on earth as to warrant the risk of death in seeking relief?" My reply to his question is that I do, and herewith venture to make a few comments.

First, it is not true that varicose veins left alone carry no mortality. Embolism from untreated varices is on record, and the fact that they are a "harsh affliction" has been and still is recognized by those dealing with the condition. Two hundred years ago Sir Everard Home tells us, "No surgical complaint incident to the soldier has deprived His Majesty's Services of so many men as that of ulceration of the leg." Again, Birger in 1941 states that in Sweden leg ulcers are a greater cause of disability than both tuberculosis of bones and joints and of diabetes put together. Again, I have called attention to the fact that 10% of the admissions to the E.M.S. hospitals during the war consisted of varicose veins and their complications. Confirmation of the "harshness" of the affliction may be obtained by a very short visit to any varicose clinic, where stinking sloughing ulcers associated with oedematous and painful limbs speak for themselves.

Although the conservative treatment of varices is commendable, active treatment with all the weapons at our disposal is essential in many cases. Sclerosants are a valuable proven adjunct in the destruction of the varix. The mortality occasioned by their proper use is infinitesimal, and the "risk of death" to which Dr. Hanschell refers may virtually be disregarded. I claim that nothing but harm can be done by Dr. Hanschell's reference to sclerosants being dangerous and useless and by his statement that they are used with incomplete knowledge, lack of controls, and without a proper follow-up. Such accusations cannot be made against any properly run clinic.

It is of interest to note that one of the many makers of a popular sclerosant tells me that he supplies over 1,000 litres

of this substance annually. This fact emphasizes the widespread acceptance of the value of these substances. I personally have used sclerosants for nearly a quarter of a century, and, whilst appreciating their limitations and the care necessary in their use, can but deprecate this attack on such a valuable weapon.

Dr. Hanschell's alternative to sclerosants apparently consists in multiple incisions running the length of the varix together with the evulsion and resection of portions of the vein. This treatment was well described by Celsus in A.D. 53 and practised by Galen some 200 years later. Since that time it has been revived and given up by various operators throughout the centuries. Dr. Hanschell says, "If the whole vein is extirpated there is, of course, no recurrence." An inspection of the anatomical ramifications of the superficial venous system should be adequate to convince any operator of the optimism of this statement.

However, all discussion regarding this fascinating subject of varices is of value, since it serves to bring out its great importance. I submit that sclerosants should be used with care and that their dosage may be further diminished in operative work by a proper prior scarification of the venous intima. Again, a special limitation of dosage should occur in all those cases presenting a previous history of deep-vein thrombophlebitis, since in such cases the intima of the deep vein may be sensitized to the effect of sclerosants. Given these and other precautions, the sclerosant is an essential and safe part of modern everyday varicose therapy.—I am, etc.,

London, W 1

R. ROWDEN FOOTE.

Brachial-plexus Block Analgesia

SIR,—Dr. J. V. Fiddian's article, "Simultaneous Embolism in Both Arms" (March 19, p. 480), raises an interesting question from the anaesthetist's point of view. The author states that he exposed the site of embolism in the right axillary artery (presumably the third part) under brachial-plexus block analgesia.

The incision in the conventional approach to the third part of the axillary artery is made through an area of skin mainly innervated by the intercostobrachial nerve (T2 and T3), and only to a lesser degree by the medial cutaneous nerve of the arm from the medial cord of the brachial plexus. According to anatomical textbooks the latter may be entirely absent.

Dr. Fiddian does not mention any additional anaesthesia or analgesia having been employed, and it would be interesting to know whether he was indeed able to perform the operation under brachial-plexus block alone, which, on purely anatomical grounds, would appear to be doubtful.—I am, etc.,

Hull.

GORDON M. WYANT.

The Mind and the Skin

SIR,—In his excellent article, "The Mind and the Skin" (March 19, p. 472), Dr. I. B. Sneddon states that he does not agree with psychiatrists that irritation of the anus and vulva always has some deep, dark, sexual significance, but acknowledges that trivial infection, tears in the mucosa, etc., may start a pruritus if the individual is at the time facing some conflict.

He then describes two cases by way of illustration, both of which have an obvious sexual basis. In the first, an obsessional, ultra-clean man gave a detailed description of his anus and perineum "which showed that he had been studying the matter closely"; and in the second, an attractive and well-dressed woman aged 36 developed pruritus when she discovered that her husband had been unfaithful to her.

Few experienced psychiatrists insist that irritation of the anus and vulva "always" has some deep sexual significance, but many, however, would agree that a certain number of pruritus cases have that significance, and certainly would not consider the two cases quoted by Dr. Sneddon as evidence to the contrary.

Dr. Sneddon suggests that even with expert psychiatric treatment, such as analysis, success is unusual in cases of pruritus in those who derive some erotic pleasure from scratching, the psychiatric explanation of which, according to Dr. Sneddon, is

a form of masturbation. This is an unscientific and unduly despairing observation, which one would not expect from such an experienced and psychologically minded dermatologist as Dr. Sneddon. Even those of us who are not psycho-analysts will not agree that it is difficult to convert erotic scratching into pruritus-free masturbation.—I am, etc.,

London, W.1.

ELLIS STUNGO.

Yearly Re-examination by Mass Radiography

SIR,—It has now been possible to analyse the results of the 1948 visit to the factory group whose yearly re-examination by mass miniature radiography was reported in the *Journal* of April 10, 1948 (p. 689). This analysis is shown in the following table. While the incidence among new employees (Group OO) remains the same as for the general population that for employees with a normal miniature film at the previous survey (Group EX) continues to be about one-third of this figure. Group EO contains those persons employed but not fluorographed at the previous visit. The volunteer response had risen to 80%.

Group	No. Examined	Observation Cases	Treatment Cases	Total (O + T)	Percentage
EX	1,351	3	2	5	0.4
EO	476	4	1	5	1.05
OO	366	5	0	5	1.4
Total ..	2,193	12	3	15	0.7

All cases were minimal in extent, with the exception of one of the treatment cases in Group EX. This was a girl, aged 2 who had had symptoms for six months. She had moderately advanced disease with a cavity in her left lung. In addition one known case was found to have relapsed.

These figures appear to reaffirm the value of the yearly re-examination of such groups.—I am, etc.,

Denham, Bucks.

W. POINTON DICK.

B.C.G. Vaccination in Finland

SIR,—In a recent publication Professor Severi Savonen¹ has given an account of B.C.G. vaccination in Finland since its introduction there in 1941. In 1942 a total of 2,500 tuberculin negative persons were thus vaccinated, whereas in 1947 as many as 61,200 persons were thus treated. Early in 1948 the Finnish National Association for Combating Tuberculosis (which has been responsible for B.C.G. vaccination in Finland all the time) entered on a campaign of mass vaccination of every tuberculin-negative person between the ages of 15 and 2 years.

This campaign was preceded by the despatch of a personal letter, accompanied by an informative leaflet, to everyone of the above age. The recipients of these letters were requested to present themselves for tuberculin testing and, in the event of their being tuberculin-negative, for B.C.G. vaccination. The association put 21 nurses at the service of this campaign, and it was only nurses who undertook this vaccination. By the end of September, 1948, this campaign had been successfully brought to an end in more than 350 of the some 480 administrative rural districts in Finland. About 30% of the Finns of the above-mentioned age were found to be tuberculin-negative. The association's plan of campaign for 1949 is to vaccinate every tuberculin-negative person in Finland between the ages of 0 and 15 years. It is the ultimate ambition of the association to ensure that everyone in Finland is tuberculin positive.

The tuberculin testing in Finland is being carried out as a modification of the method described in 1929 by the Italian Bruno Trambusti. The B.C.G. vaccine is flown by air mail once a week from Gothenburg to Finland, and the tuberculin is supplied in the form of old tuberculin by the State Serum Institute in Copenhagen.—I am, etc.,

Sunnefjord, Bergen, Norway.

CLAUDE LILLINGSTON.

POINTS FROM LETTERS

Analgesia in Childbirth

Dr. O. CAIGER SMITH (Nottingham) writes: In view of the popular and parliamentary interest in the matter of analgesia in childbirth it is surprising that one simple apparatus, already existing primarily for this purpose, has not received more mention. The Young-Simpson inhaler is scarcely mentioned in the books and is rarely described. Consisting of a Woulfe's bottle, a rubber tube, and a face-mask with a variable outlet valve, it delivers to the patient an amount of analgesic commensurate with the amount of pain. Air is drawn through the long metal tube of the Woulfe's bottle, through the anaesthetic, through the short metal tube via the rubber tube to the face-mask. Expired gases pass without obstruction through the simple valve on the face-mask. The valve is so arranged that gentle breathing prevents it from working and pure air only is drawn in. The effect of all this is that severe pain induces a deep breath and provides the patient with a relatively large amount of analgesic at once, while a lesser breath, induced by a lesser pain, draws over a lesser amount of analgesic. The pain centre makes direct arrangements with the respiratory centre. "Trilene" is the anaesthetic of choice at the moment and suits this apparatus very well, though I have had no trouble with chloroform. The apparatus is light and portable, and has an additional advantage over the N_2O machines in that the reserve supplies of anaesthetic can be easily seen, so that there is no danger of the drug running out in the height of battle. I have had no trouble in teaching the use of this apparatus to midwives in a few minutes, and many have wondered why it is not more universally used. I have employed it myself for twelve years to the great satisfaction of patients and myself. The two important rules to ensure absolute safety and effectiveness are: (1) Do not put more than about one inch of trilene in the Woulfe's bottle, and (2) Make sure that the patient has the mask sufficiently firmly applied so that on inspiration air is heard bubbling through the Woulfe's bottle. A loose application to the face means little or no analgesia.

Child Welfare in Africa

Dr. J. O. SHIRCORE (Fort Johnston, Nyasaland) writes: Mr. Norman Emblin's paper entitled "5,000 Consecutive Deliveries without a Maternal Death due to Pregnancy" (Feb. 12, p. 260) is a splendid example of what can be achieved by thorough organization and administration. It may not, however, be out of place—especially as African affairs are now to the forefront—to refer those interested to the *Tanganyika Territory Annual Medical Report of 1928* (pp. 105-115), in which detailed statistics are given. In this connexion a paragraph from a "Memorandum on the Improvement of Physique of the Native" by the director of medical services of the day (1930) refers to that report as follows: "The death rate for the first ten days of life at the Kahama Clinic, at which 1,129 children were born during 1928, was less than 30 per 1,000." Miss Allardes, nursing sister and health visitor, later matron of the nursing service, was in charge, and she, together with a staff of six African female assistants trained by her, dealt with the whole of that number in the year. The Kahama Clinic was situated at a small district headquarters 80 miles north of Tabora and 35 miles directly west of the Tabora-Mwanza railway, on a road frequently cut off during the rainy season—"out in the blue."

Vitamin A for Iridocyclitis

Dr. DOROTHY MATTHEWS (Johannesburg) writes: During the past four years I have had four attacks of iridocyclitis. These were apparently precipitated by periods of over-work, and no source of infection was found to account for them. The first attack lasted about two months, but the next two were shorter. Sulphonamides and penicillin seemed to have helped a little in these two; during the first only local heat, atropine, and analgesics were used—morphine being necessary for the worst part of the attack. The last bout occurred just over two months ago. I wondered if it might have a dietetic origin, as I dislike fats in general. I took 350,000 units of vitamin A orally immediately, and 60,000 b.d. for the following three days. Within 24 hours of the first dose there was marked improvement. I had inserted no atropine, and the photophobia had gone. There were still physical signs of iridocyclitis, confirmed by an ophthalmologist. Previously I associated vitamin A therapy with corneal conditions only, but in the light of this experience I wonder how many idiopathic cases of iritis may not benefit by similar treatment.

The Ministry of Health states that over 380,000 blood donations were received by the National Blood Transfusion Service last year—90,000 more than in 1947. More blood was used in hospitals in England and Wales last year than in 1944, the peak year of the war. Nearly 100,000 new donors joined the National Blood Transfusion Service in 1948, making a total of 373,778 donors in England and Wales. But to provide for future needs and to reduce calls on existing donors another 200,000 are wanted.

Obituary

PROFESSOR ERNST SCHMIEGELOW

Professor Ernst Schmiegelow, of Denmark, who died on Feb. 28, was a remarkable figure in the world of otolaryngology. Not only was he the first in Denmark to hold a professorship in this field, but he was also the first in his younger days to wrest otolaryngology as a specialty from the general surgeons. He was born on Oct. 13, 1856. When, a few years ago, at the age of 90, he published his autobiography, based on his diary, he succeeded in painting a vivid picture of the world of medicine in a great part of two centuries. An indefatigable traveller and participator in international medical conferences, this urbane Dane came to know and to be known by the leading medical men throughout the world, and his younger fellow-countrymen soon learnt how letters of introduction from him opened countless doors abroad. When in 1883 Schmiegelow opened a polyclinic for patients with diseases of the ear and throat in Denmark the surgeons did their best to put him out of countenance. In 1929 Schmiegelow's standing in his own specialty was officially recognized by his selection as president of the First International Oto-Laryngological Congress in Copenhagen.

Dr. VICTOR DAMIAN PENNEFATHER died in Southampton on March 25 at the age of 53. In 1917 he qualified in Singapore, and after working there and at Dar-es-Salaam he came to England and became a student at the London Hospital. He served as a captain in the R.A.M.C., and in 1922 obtained the Conjoint diploma. He then worked at Lyndhurst, in the New Forest, for a number of years, and finally took over a busy practice in Southampton. The strain of overwork during the recent war was a factor in the development of the illness which forced him to retire two years ago. Dr. Pennefather was conscientious and able, and he was an active member of the B.M.A. and the Southampton Medical Society. He was well liked by his patients and colleagues, and will be missed by many. He showed great fortitude and patience during his prolonged and trying illness, and the sympathy of his colleagues and friends will be extended to his wife, who nursed him during his illness—S. N. L.

Dr. HERBERT EBENEZER EDLIN died at his home in Levenshulme, Manchester, on Feb. 23 at the age of 86. Dr. Edlin was educated at Manchester Grammar School and at Owens College, qualifying in 1884. In that year he succeeded to his father's practice and was also appointed medical officer of health for Levenshulme, an appointment which he resigned only in 1909 after twenty-four years' service. He was interested in the work of the St. John Ambulance Brigade and was for many years a lecturer and examiner in first-aid. During the 1914-18 war he acted as honorary secretary to the local Red Cross hospital, and was also on the staff of the military hospital at Alma Park. In the recent war he took charge of a first-aid post at Stanley Grove, and he only retired from practice in October, 1947, a few months after his 85th birthday. Dr. Edlin had lived in Levenshulme since early childhood, and he saw it grow from a village with a population of about 2,500 to its present size. He was popular with his patients and greatly esteemed by his colleagues. The sympathy of all who knew him will be extended to his widow and his son.

Mr. ARTHUR HERBERT BUCK, who died at Dereham, Norfolk, on March 9 at the age of 79, had a distinguished surgical career in Sussex up to his retirement in 1921. As a boy he had a voice of great beauty and was a chorister of King's College Chapel, Cambridge. He perhaps inherited some of the musical talent of his grandfather, Zachariah Buck, the renowned organist of Norwich Cathedral. After qualifying from St. Bartholomew's Hospital in 1892, the year in which he won the Brackenbury Scholarship, he became senior house-surgeon at the Royal Sussex County Hospital, Brighton, and remained there for three years. He was elected assistant surgeon to the hospital in 1899, two years after he had taken the F.R.C.S.Ed., and full surgeon in 1909. Buck was full of zeal for the then new aseptic technique and was the first to practise it in Brighton. He soon became known as a bold and dexterous surgeon, and for many years he and the late Mr. Reginald Jowers shared between them most of the surgical work of Brighton and mid-Sussex. Buck was also surgeon to the Brighton and Sussex Throat and Ear Hospital from 1901 onwards. Though of all-round ability, his special leaning was towards abdominal

surgery, in which he excelled. He took great pains with his after-treatment, often employing original methods, some of which stood the test of time while others did not. Buck was attached to the 2nd Eastern General Hospital during the 1914-18 war, with the rank of major. After the war ended he retired at a somewhat early age and took himself and his family to Vancouver Island, where they spent twelve happy years. He had always been an enthusiastic yachtsman, sailing on the south coast and the Norfolk Broads, and he was an equally fine fisherman. These two hobbies he was able to enjoy to the full from his home on the Island. When the time came for his son, John, to start his medical studies in Edinburgh, the family returned to England. Some financial losses had been suffered, and with characteristic resolution Buck decided to get into harness again. Surgery held no prospects after twelve years' absence, so he proceeded to do "locums" in Norfolk and elsewhere until his son had qualified. Six years ago Buck was stricken by a fatal illness and underwent several operations. These and their attendant discomforts and anxieties he met with much fortitude, always cared for by his devoted wife. Her sudden death, eighteen months ago, shattered him, and the end came with a kindly hand. His life had held both storm and sunshine, and in all circumstances his outstanding virtue was courage.—H. N. F.

Dr. HENRY COLIN MACLAREN, who died in Carlisle on March 17 at the age of 37, was honorary anaesthetist to the Cumberland Infirmary and the Carlisle group of hospitals. He was born in Carlisle, and was the youngest son of the late Norman Maclaren, F.R.C.S., who was honorary surgeon to the Cumberland Infirmary, Carlisle. He was educated at Oundle, Trinity College, Cambridge, and St. Bartholomew's Hospital. He graduated in 1937 and took the D.A. in 1940. After resident appointments at St. Bartholomew's Hospital and at Winchester he returned to Carlisle and was appointed anaesthetist to the Cumberland Infirmary in 1939. From 1942 he served in the R.A.M.C. as a specialist anaesthetist in North Africa, Italy, and Austria. On demobilization in 1946 he took up practice in Carlisle again. Dr. Maclaren was honorary secretary of the Border Counties Branch of the British Medical Association, and had previously been honorary secretary of the Cumberland Division. With the death of Colin Maclaren, Carlisle has lost a man of great promise. He had a happy personality, and he proved in his last long illness how great was his courage. He is survived by a widow and two young sons, to whom the sympathy of many friends and colleagues will be extended.—F. J. S.

Dr. THOMAS MORRISON CLAYTON, who died on March 21 after a long illness, had a distinguished career as medical officer of health and school medical officer of Gateshead. Dr. Clayton was born at Felling in 1870, graduated at the University of Durham in 1894, and practised in his native town for some years, becoming its medical officer of health in 1896. Six years later he succeeded Dr. R. Greene as the fourth whole-time medical officer for Gateshead, a town which shared the unenviable reputation of industrial Tyneside generally as an unhealthy area. He belonged to the generation for which preventive medicine was mainly directed to improvements in environment and the control of infectious diseases. He became an expert epidemiologist, with considerable experience of outbreaks of smallpox and typhus, being much concerned with the last two local outbreaks of the latter disease in 1907 and 1910. It was also in 1907 that Dr. Clayton initiated school medical inspection in Gateshead, and he organized the maternity and child-welfare clinics there in 1919. Throughout his service he was medical superintendent of Sheriff Hill Isolation Hospital, and he started the extension of the Gateshead municipal hospitals with the opening of Whinney House Sanatorium in 1925. In the sphere of hospital development Dr. Clayton was gravely handicapped by the poverty of the town, which became a "distressed area" in the post-war slump, and he had retired from active work before the grants from the Special Areas Commissioner became available for the building of the new municipal hospitals, which were the logical result of much of his work. His retirement in 1936 brought to an end his thirty-four years' service in Gateshead. Clayton was an authority on infectious diseases and one of the earliest to criticize the theory of the aerial convection of smallpox, ascribing the apparent examples of such spread rather to human contact, a thesis which in 1905 he put before the leading sanitarians of the country. In 1908 he was elected a fellow of the Royal Society of Edinburgh. An excellent raconteur, he had the knack of smoothing out administrative and other difficulties with a well-timed and pointed anecdote. He is survived by two daughters and three sons; one son is a veterinary surgeon and two are medical officers of health. To all his family the sympathy of his colleagues and friends will be extended.—J. G.

Dr. C. Lillingston writes: Dr. J. R. Conner (March 26 p. 549) used to describe himself as a literary hack. To those who knew him well this was an understatement with vengeance. To be sure, he was a master of the technical side of medical journalism, and he took infinite pains in practising and teaching the reporting of medical news in concise English purged of all that was slipshod. Such redundancy a "curiously enough" was anathema to him. Why, he would ask with intense exasperation, do you drag in "enough" when you know quite well that here it means nothing at all, at all? The *Medical Review*, which Conner owned and edited for many years, was devoted exclusively to abstracts of original articles published at home and abroad. Here he revelled in the delicate and responsible task of sifting the wheat from the chaff. At later stage he was the tireless and efficient editor of the *Clinical Journal*. Conner was still less of a literary hack in the part he played as the regular London correspondent of the *Journal of the American Medical Association*. Here he had full scope for his talents as a shrewd observer of, and commentator on, the world of medicine. As a reporter of events he was impartial and objective. He was so, too, as a biographer. But when, as happened occasionally, the subject of a medical biography inspired him, he came out of his shell, a self-confessed hero worshipper. He did so in prose of a quality which recalled the saying that it takes an Irishman to write the best English. Conner was Irish to the marrow, from his ancestry to his brogue. But he was very appreciative of the Anglo-Saxon character, though when he referred to the Anglo-Saxon's love of compromise he did so rather as the detached observer of a natural phenomenon than as a breathless admirer of it. For truth to tell, Conner had no taste for compromise when the rights and wrongs of a case were self-evident. Indeed, his uncompromising rectitude must often have troubled him, as much as it won the admiration of the friends who knew him best.

Medico-Legal

N.H.S. TERMS OF SERVICE

Doctor Censured

The Derbyshire Executive Council at its meeting on Feb. 1 unanimously approved a report from the Medical Service Committee recommending that a doctor should be severely censured and that a sum of £10 should be withheld from his remuneration.

The committee had investigated a complaint made against a medical practitioner by the father of a baby girl, aged 1 months, who died on Nov. 27, 1948. The substance of the complaint was: (1) that although three urgent requests for visit by the doctor were made on Saturday, Nov. 27—namely at 7.55 a.m., 4 p.m., and 5.30 p.m.—no doctor arrived until 6.30 p.m.; (2) that no examination was made until Saturday Nov. 27, 1948, when an assistant doctor examined the child. The complainant attended the hearing and brought with him as witnesses his wife and mother-in-law. The respondent doctor (who is in partnership with another doctor and has two assistants) attended but did not bring any witnesses.

It was accepted in evidence that the name of the doctor was included in the Council's Medical List, and that, having signed Form E.C.16, he had undertaken to accept service and to be bound by the terms of service in operation in the area; also that the deceased child was accepted by the doctor and registered on his list with effect from July 5, 1948.

The father stated that on Tuesday, Nov. 23, his child started to vomit and pass a green motion; that on Wednesday, Nov. 24, 1948, he telephoned to the doctor's surgery; that one of the assistant doctors arrived at the house and prescribed tablets but did not make any examination. On the night of Thursday Nov. 25, the child started to breathe heavily, and on the following morning the father again telephoned to the doctor's surgery. The other assistant came to the house, saying that the child's condition was due to the effect of the tablets and that there was nothing to worry about. The father was emphatic in stating that on the occasion of both visits no examination was made. On Saturday, Nov. 27, on returning from work at 6.30 a.m., the complainant said his wife and mother-in-law told him they had been up all night with the child, and at 7.55 a.m. he went to the house of the doctor, whose wife answered the

door, and told her his daughter was very ill and breathing heavily. The doctor's wife said she would speak to the doctor. The father asked her to inquire of the doctor if it would be all right to give the child a drop of brandy. The doctor's wife came back with the message "not to give any brandy but that the doctor would come along." At 4 p.m., as the child was gasping for breath and no doctor had arrived, the father said he again telephoned the doctor, whose wife answered the telephone and said one of the doctors would call. The father went on to say that at 5.30 p.m. still no doctor had arrived, and he telephoned again and was answered by the doctor's wife, who said, "Hold on whilst I speak to the doctor," and that when the doctor's wife again answered she said it was one of the assistant doctors' "off-duty" day but that the other assistant would call. At 6.30 p.m. the assistant doctor arrived, examined the child, and said it was pneumonia. At about 7.30 p.m. the same night an ambulance arrived and the child was taken to hospital, arriving there about 9 p.m. The child died between 10.30 and 11 p.m. the same evening from bronchial pneumonia. The complainant's statement was corroborated in evidence by his wife and mother-in-law.

The respondent doctor in his statement maintained that there was no neglect and that by prescribing sulphapyridine tablets the necessary precautions had been taken. The doctor further contended that there was no serious condition of the child until the morning of Saturday, Nov. 27, and that following the early-morning call by the complainant he left a note on the assistant's desk so that it would be seen immediately on the assistant's arrival for the morning surgery. He made the admission, however, that he had quite forgotten it was the assistant's "off-duty" day. The doctor stated that directly after returning from visiting patients at 6 p.m. one of the assistants went to see the child.

After a lengthy hearing the committee found as follows: (1) That it was not until approximately 6.30 p.m. on Saturday, Nov. 27, 1948, that the assistant doctor visited the child, although the complainant personally delivered an urgent message at the doctor's house at 7.55 a.m. that day, followed by two further telephonic requests made by the father at approximately 4 p.m. and 5.30 p.m. (2) That up to Saturday, Nov. 27, the committee found no evidence of inattention. (3) That there was a degree of negligence on the part of the principal doctor in not responding more promptly, either personally or by deputy, to the father's request made on the morning of Saturday, Nov. 27, 1948.

The committee recommended: "That the doctor be severely censured and warned to exercise more care in the observance of his terms of service under the National Health Service Act, and that representations be made to the Minister that, owing to the failure of the doctor to comply with the terms of service, a sum of £10 be withheld from his remuneration."

Medical Notes in Parliament

Psychiatric Treatment of Homosexual Offenders

Replying on March 28 to Mr. WILKINS, Mr. EDE stated that no psychiatrists were employed full-time in the prison service. Six were engaged in a part-time capacity. Five prison medical officers possessed special psychiatric qualifications, and many others had mental hospital experience. There were now 412 prisoners serving sentences for homosexual offences. Prisoners convicted of these offences who in the opinion of the medical officer might benefit by psychiatric treatment were transferred to the prisons at which there were psychiatric clinics if their sentences were long enough. During the past six months 40 homosexual offenders received psychiatric treatment at these centres, and, of those at present under sentence, 35 additional cases had received psychiatric examination and guidance at other prisons. Arrangements had also been made to extend the psychiatric service available to prisoners who might benefit from treatment but could not be removed to the special centres. Research, partly therapeutic in character, into the psychological and endocrinological aspects of homosexuality was being conducted at two selected prisons, and homosexuals might also benefit from research now in progress into psychopathic personalities.

Universities and Colleges

UNIVERSITY OF LIVERPOOL

S. Ghouseuddin has been approved for the D.P.H. (Part I).

UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—R. C. Gledhill, J. S. Thorburn.
CH.M.—R. A. Hall, R. E. Shaw.
FINAL M.B., CH.B.—Part III (*Medicine, Surgery, Obstetrics and Gynaecology, Therapeutics*): Nora E. Brown, D. Burrell, Hazel M. Coleridge, R. S. Colwyn, E. L. Copley, Frances M. Cottam, P. H. Daley, W. P. Goodyear, Ida Mather, J. E. Miller, Anne B. Neil, Cynthia M. Periman, K. Platts, Mary C. Robertson, J. Sagar, M. H. Singer, Doreen W. Steinbrecher, D. J. Stephens, Joyce M. Tensdale, Margaret Winton. Part I (*Pathology and Bacteriology, Pharmacology*): Margaret Anderson, Cynthia Barnett, Audrey M. Bolton, Dorothy Broomhall, Jean M. Burnett, E. M. Calverley, J. I. Currie, T. G. Dobie, D. Duncalf, M. Dunsby, W. G. C. Forrester, Mary Hollowell, Marion Hanson, J. G. M. Harrison, Anne E. T. Haw, Marjorie Haw, T. E. Heath, J. M. Hirst, B. R. G. Hutchinson, Margaret Hyde, Mary McMillan, R. J. Mahabir, P. Mellor, E. Morton, K. A. Naylor, A. Nugent, Margaret Penny, Mary G. Pullan, Margaret Rogers, R. E. Rossall, P. B. Rowe, Audrey W. Scothorne, J. A. Sharp, M. W. Sharp, S. Sheffrin, P. D. Sinclair, K. Stewart, K. R. Thornton, F. W. Turner, D. C. Twist, Barbara M. Wadsworth, E. R. Watson.

¹ Distinction in Pharmacology. ² Distinction in Pathology and Bacteriology.

The following Scholarships and Prizes have been awarded: *Medical Scholarship*, R. Beaumont. *McGill Prize in Clinical Surgery*, E. L. Copley. *Waddington Prize in Anatomy*, D. N. Laurence.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Croonian Lectures, on "Malaria, with Special Reference to Recent Experimental, Clinical, and Chemotherapeutic Investigations," will be delivered by Dr. N. Hamilton Fairley, F.R.S., before the College (Pall Mall East, S.W.) on Tuesday and Thursday, May 3 and 5, at 5 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Professor Robert I. Harris, Associate Professor of Surgery in the University of Toronto, has been elected an Honorary Fellow of the Royal College of Surgeons of England. He will be admitted as an Honorary Fellow on April 29, when he will deliver before the College (Lincoln's Inn Fields, London, W.C.) a Hunterian Lecture on "Spondylolisthesis."

SOCIETY OF APOTHECARIES OF LONDON

Professor E. C. Dodds, F.R.S., presided, as Master, at recent meetings of the Court of Assistants. Dr. J. P. Hedley was re-elected to represent the Society on the Central Midwives Board for a further year from April 1. The Society's Gilson Scholarship in Pathology will in future be awarded every third year, beginning in 1952, in the sum of £500. It was resolved to confer the Honorary Freedom of the Society upon Sir Charles Harington, F.R.S., in recognition of his work in the field of biochemistry and chemical pathology. The Gold Medal of the Society for 1949 will be bestowed upon Professor Jacques Tréfoüel, Director of the Institut Pasteur, Paris, in May, in commemoration of his contribution to scientific advancement in the field of therapeutics. The report of the death in a railway accident of Dr. Francis S. Curd, Gold Medallist, was received with regret. A further course of ten lectures on modern therapeutics will be given in the week beginning Dec. 5 next.

The Diploma of Mastery of Midwifery was granted upon examination to G. Bridge.

The following were granted the Diploma in Industrial Health upon examination: N. Graham, T. G. Jones, G. M. MacBain, T. E. M. Wardill.

The Diploma of L.M.S.S.A. was granted upon examination to the following successful candidates: H. H. B. Perkins, C. M. D. Davies, M. A. R. Stilson, H. D. Isaacs, A. Paez, M. J. Beilin, J. A. A. R. Venniker, E. G. Dimopoulos, M. Callier, J. K. Jones, M. G. Kaye, T. Bell, J. R. Deacon, D. L. Stilson, J. D. Whittall, T. Brearley, J. R. Dyson, T. Pimblett, C. Jones, R. W. E. Brain, R. Raynham, N. H. Porter, R. F. Maddox, D. L. Stewart, A. P. Caspers, R. Payne, G. Williams, H. G. Damant, B. E. L. Thompson, N. H. Bamford, E. F. Stafford, M. H. Symes, E. A. Brown.

The High Commissioner for Eire has asked that when it is found desirable to transfer patients to hospitals in Eire the transfer should be arranged through his office and not directly with the hospital in Eire. Hospitals which are arranging to transfer patients should send full particulars, including a medical report and information about the district to which the transfer is desired, to the High Commissioner at 33-37, Regent Street, London, S.W.1. The High Commissioner's Office will then make whatever arrangements are possible for the reception of the patient.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland
 Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland
 A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Smallpox

A passenger aged 69 who became ill about March 21 on board the s.s. *Mooltan* during a voyage from Australia died at sea on April 1. The fatal illness, at first believed to be chickenpox, was later found to be smallpox. The ship arrived in the Port of London on April 2 with 953 passengers and 441 crew. All except two of these persons were either vaccinated or revaccinated before leaving the ship on April 3. Local health authorities are being advised of the names of these persons and of the addresses to which they have gone, also of the names and addresses of a number of persons coming to the United Kingdom who left the ship at Marseilles on March 25 without being vaccinated. The widow of the passenger who died was taken ill on April 3 and has been removed to a smallpox hospital. Passengers and crew on the ship were at risk of being infected by smallpox for about a week before they were vaccinated or revaccinated. The vaccination of contacts after exposure to infection cannot be relied upon to afford complete protection, and there is a likelihood that further secondary cases may appear during the next fortnight. Medical practitioners called to see any passenger or member of the crew from the s.s. *Mooltan* during the next few weeks are asked to consider the possibility of smallpox, and if in doubt to inform the local medical officer of health, who will be prepared if necessary to obtain the advice of a consultant.

Influenza

There were 327 deaths in the great towns in the week ended March 26 as against 360 in the previous week. The numbers increased in the Midlands, but decreased elsewhere. The majority of the deaths occurred in old people. This fall in the weekly total of deaths brings to an end an increase that has continued over the past seven weeks. An exceptional feature of the present outbreak has been the persistence of a rising mortality so late in the year. The latest period for a maximum figure during recent years was the eighth week in 1940. The number of deaths occurring in the first eleven weeks of this year is the largest for the past ten years except for 1941 and 1946.

Provisional Figures for 1948

Provisional figures given in the Registrar-General's return for the quarter ended Dec. 31, 1948, show that the general death rate in 1948 was the lowest ever recorded in this country. It was 10.8 per 1,000 total population, compared with 12.0 in the previous year and the previous lowest figure of 11.4 in 1930 and 1945. The infant mortality rate was 34 per 1,000 related live births. This is the first time the annual rate has fallen below 40 and is an improvement of 7 per 1,000 on the previous lowest in 1947. The improvement in infant mortality in this country in recent years compares favourably with the experience of other countries, although some still have lower rates—for example, the provisional 1947 rate for Sweden was 25. The proportion of stillbirths to total births was 23.1 per 1,000, or 1.0 lower than the best previous figure, which was also in 1947.

There was a fall in the birth rate from 20.6 per 1,000 total population in 1947 to 17.9 in 1948, but the effective reproduction rate (provisional) is still above one. Included in this return are three graphs which give a comparison of the numbers of live births, deaths, and marriages during and after the two world wars.

The total population of England and Wales at June 30, 1948, is given as 43,502,000 (males 21,091,000, and females 22,411,000). Projections of the total population of England and Wales by sex and age to mid-1950 and mid-1960 give the total population at those dates as 43,685,000 and 44,906,000 respectively: these projections are, of course, made upon certain assumptions—for example, that births will be at the rate of 700,000 per annum to mid-1955 and at the rate of 650,000 thereafter. A summary of these projections shows how the proportions of children and of people over 45 years of age in the population are expected to increase at the expense of the younger adult population.

Discussion of Table

In England and Wales an increase was recorded in the notifications of whooping-cough 169, scarlet fever 31, cerebrospinal fever 22, and diphtheria 13. There was a decrease in the incidence of measles 1,030 and dysentery 14.

The largest falls in the notifications of measles were Staffordshire 196, Southampton 164, Cheshire 126, Warwickshire 114, Yorkshire West Riding 113, and Worcestershire 104. The incidence of measles increased in London and the surrounding counties in contrast to the remainder of the country; the largest rises were London 197 and Kent 92.

Oral therapy for urogenital analgesia

'PYRIDIDIUM' administered orally in a dosage of 2 tablets t.i.d., promptly relieves such symptoms as painful, urgent, and frequent micturition, nocturia, and tenesmus. 'Pyridium' acts directly on the mucosa of the urogenital tract; its characteristic

analgesic effect is entirely local, and it is not associated with or due to systemic sedation or narcotic action. Therapeutic doses of 'Pyridium' may be administered with virtually complete safety in most cases of infection or irritation of the urogenital tract.

Samples and literature on request

● Pyridium is the registered trade mark of the Pyridium Corporation of New York to designate its preparation of phenyl-azo-a-a-diamino-pyridine hydrochloride. Each tablet contains 0.1 g.

CONTINUOUS PERFORMANCE

In Gelusil* Tablets the recognizedly prompt and effective antacid virtues of aluminium hydroxide are fortified by magnesium trisilicate to provide sustained neutralization in peptic ulcer and related hyperchlorhydric states.

Gelusil contains a specially processed, partially dehydrated alumina which is virtually incapable of reacting to produce soluble chloride; "alumina constipation" is thus practically eliminated. Gelusil provides prompt, uncomplicated and continuous antacid therapy.

THE INTRAVAGINAL TAMPON IN MENSTRUAL HYGIENE

An important clinical study

*Significant facts
obtained by the close
observation of 25 parous
and nonparous women*

In view of the increasing use of the intravaginal tampon for the absorption of the menstrual flow, the following important study was undertaken to determine whether or not this method of sanitary control is safe and not prejudicial to health.

Twenty-five women—parous and nonparous—were selected and were under daily institutional observation during two successive catamenial periods. Ranging in age from twenty-one to forty-five, some had previously used tampons, others had not.

The following summary indicates clearly the findings of the study.

1. In not a single instance was there any evidence of local irritation brought about by the use of the tampons.

2. No uterine cramps, suggestive of block of the uterine flow or damming back into the tubes were reported in any case of this series.

3. No bladder irritation was reported.

4. The average number of tampons used in a period was ten.

5. In cases in which a cervical erosion was present, neither the amount of bleeding nor the character of the erosion was altered by the use of the tampons.

6. There was no appreciable difference in the bacterial flora of the vagina and after the use of the tampons during the menstrual period.

7. There was no appreciable difference in the pH of the vaginal or cervical secretions before menstruation and after the use of the tampons during the period.

8. Absolute comfort and complete absorption of the flow was obtained by the proper correlation of the size of the tampon with the length and calibre of the vagina.

9. The evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health.

TAMPAX

If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

Watson X-Ray Apparatus WORKS RELIABLY AND WELL

Long experience has taught us how to make X-ray apparatus on which the user may rely implicitly. Electrically and mechanically, it is built for continuous use under all climatic conditions with the minimum of interruption for maintenance.

Radiologists throughout the world specify Watson equipment certain in the knowledge that it embodies the best features of contemporary design.

We will gladly submit proposals for the layout of modern X-ray departments on request.

KINGSWAY, LONDON, W.C.2

The largest local variation in the notifications of scarlet fever was an increase of 24 in Essex. Notifications of diphtheria increased by 9 in Lancashire. The largest rises in the incidence of whooping-cough were Yorkshire West Riding 44 and London 32.

Only 35 cases of dysentery were notified—the lowest weekly total since December. The 57 notifications of cerebrospinal fever provided the largest total for over a year; the cases were scattered throughout the country.

In Scotland increases were reported in the notifications of measles 128 and whooping-cough 41. The 13 notifications of dysentery gave the lowest figure for over a year. Notifications of scarlet fever increased by 16 in the south-eastern area but declined in the other areas.

In Eire there was a fall of 19 in the notifications of measles and a rise of 36 in the incidence of scarlet fever. Only 18 cases of diarrhoea and enteritis were notified, the lowest total during recent months. The chief centres of scarlet fever were Dublin C.B. 72 and Donegal, Stranlar R.D. 31. Of the 118 cases of measles 95 were notified in Dublin C.B.

In Northern Ireland a fall was reported in the notifications of measles 14, and there was a rise in the incidence of scarlet fever 22. The notifications of measles rose by 24 in County Antrim and fell by 42 in County Down. The rise in the incidence of scarlet fever was general throughout the country.

Health of Scotland in 1948

Infant mortality in 1948 reached the record low level of 44.7 per 1,000 compared with 55.8 in 1947 and 59 as the average of the past five years. The general mortality was 11.8 per 1,000. Deaths from respiratory tuberculosis numbered 3,417, which was 28 more than in the preceding year. The increase in the notifications of respiratory tuberculosis continued. The provisional figure for 1948 is 8,010, which may be compared with 4,657 in 1939. The figures for non-respiratory tuberculosis showed an improvement; deaths and notifications were 221 and 250, respectively, fewer than in 1947.

Week Ending March 26

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,357, whooping-cough 2,978, diphtheria 117, measles 15,307, acute pneumonia 1,547, cerebrospinal fever 39, acute poliomyelitis 15, dysentery 34, paratyphoid 7, and typhoid 3.

Medical News.

Proceedings of the Annual Meeting, 1948

The volume of the *Proceedings* of the Association's Annual Meeting at Cambridge last year has been published (Butterworth and Co., London) and is reviewed on p. 620. Between Sir Lionel Whitby's presidential address, with which the book opens, and the lecture on "Accident and Opportunism in Medical Research," by Sir Henry Dale, O.M., F.R.S., with which it ends, leading authorities on the science and practice of medicine, including surgery and obstetrics, discuss the recent advances in their own specialty. The book is attractively produced and contains a subject index.

Dr. Garrett Brownrigg

Dr. Garrett Brownrigg, formerly President of the Newfoundland Medical Association and Physician at Government House, Newfoundland, has been appointed C.B.E. (Civil Division).

Women in the Community

The Liberal Party Assembly recently discussed women's place in the community and in the health services. Mrs. Wendy Wills moved that there should be a common portal of entry into the nursing profession with 18 to 24 months' basic training. Passing an examination at the end of the course would give the right to State registration as an "enrolled nurse." An advanced course would be taken for qualification as a State-registered nurse. Efforts should be made to attract and train as "nursing aides" women who cannot undertake the full basic training but wish to be associated with the care of the sick. She had found that only a small minority felt a call to enter the nursing profession; the choice was often governed by the important factor that the training was largely free. Hospital posts were hard to fill mainly because of hours of work, pay, and personal freedom compared unfavourably with conditions offered in public health and welfare services and in industrial nursing, where applicants outnumbered vacancies. Mrs. Doreen Gorsky emphasized that men and women must be regarded as equal partners in marriage, and moved that more adequate maintenance allowances should be made legally possible, particularly where there are young

children. The wife and children should have greater protection from the man who tries to evade his obligations for maintenance, and the courts should be able to give both parties an equitable share of the contents of their home and savings acquired by their joint effort during marriage.

Blood Transfusion Research Committee

The Medical Research Council has decided to reconstitute its Blood Transfusion Research Committee to advise and assist it in dealing with new problems arising in the course of work on dried blood and dried-blood products. The following have been appointed as members of the new committee in the first instance and have agreed to serve: Dr. A. D. Drury, F.R.S. (chairman); Dr. R. J. Drummond, Regional Blood Transfusion Officer, Cardiff; Mr. R. A. Kekwick, D.Sc., the Lister Institute; Dr. J. F. Loutit, Director of the M.R.C. Radiobiological Research Unit, Harwell; Dr. R. G. Macfarlane, clinical pathologist, Radcliffe Infirmary, Oxford; Dr. M. Maizels, clinical pathologist and University Reader, University College Hospital; Dr. d'A. Maycock, the Lister Institute, adviser on blood transfusion to the Ministry of Health; Dr. P. L. Mollison, Director of the M.R.C. Blood Transfusion Research Unit; and Dr. R. R. Race, Director of the M.R.C. Blood Group Research Unit.

Trained Nurses' Salaries

In view of the dissatisfaction felt by trained nurses throughout the country on delay in arriving at a decision about revision of their salaries the Staff Side of the Nurses and Midwives Whitley Council state that proposals for certain revisions were submitted to the Management Side on Feb. 1. A meeting with the Management Side was arranged and was later postponed at the request of the Management Side. The postponed meeting fixed for a later date was also cancelled by the Management Side. On the Staff Side's approaching the Minister it was learned that the claim, which raises issues of considerable financial importance, is being considered, and it is hoped that the Management Side will shortly be in a position to reply to the Staff Side's proposals.

Care of Whalemeat

The Food and Drugs (Whalemeat) Regulations, 1949, which came into operation on March 20, govern the importation of whalemeat into England and Wales and the conditions for storing and selling it. The regulations require a veterinary certificate for whalemeat and whalemeat products intended for human consumption. The whalemeat must have been inspected and produced in accordance with conditions satisfactory to the Minister of Food. The regulations are to be enforced by port health authorities and local authorities. A memorandum has also been issued setting out the conditions for transporting, packing, and storing whalemeat and the provisions for inspecting it. The memorandum will be reviewed in the light of experience gained during this season's whaling expeditions in the Antarctic.

Wills

Dr. John Bruce, a former provost of Forres, left £37,122. Dr. Frederick John Blackley, of Southampton, left £27,211; and Dr. Edward John Cross, of Eynesbury, Hunts, £7,043. Mr. Albert Edwin Hayward Pinch, formerly director of the Radium Institute, London, left £27,924; after making a number of bequests he left the residue of his estate to his wife for life, with remainder as to half to the Medical College of St. Bartholomew's Hospital, to help necessitous students, and half to the Faculty of Medicine of the University of Bristol, similarly.

COMING EVENTS

Regional Consultants Committee for Oxford

A meeting of the Oxford Region Consultants and Specialists Committee will be held at Radcliffe Infirmary, Oxford, on April 10, at 3 p.m., to discuss the proposed terms and conditions of service of hospital medical and dental staff.

British Orthopaedic Association Meeting

The spring meeting of the British Orthopaedic Association will be held at Nottingham in the Great Hall of the University on April 22-23. The programme includes the following papers. April 22: Mr. D. Trevor on "Spontaneous Rupture of Extensor Pollicis Longus Tendon following Colles' Fracture"; Mr. N. W. Roberts on "Osteochondritis Desiccans of the Elbow Joint"; Mr. T. Rowntree on "Anomalies in the Innervation of the Muscles of the Hand"; Mr. R. G. Pulvertaft on "Tendon Surgery in the Hand" (film). April 23: Mr. P. C. Elmes on "Fractures of the Neck of the Femur"; Mr. R. C. Murray on "Trochanteric Fractures of the Femur"; Mr. J. Rowland Hughes on "Radiological Diagnosis of Recent Lesions of the External Lateral Ligaments of the Ankle"; Professor J. Delchev on "Nerve-root Pain of Vertebral Origin not Dependent on Disk Prolapse"; Mr. E. Mervyn Evans on "Pronation Fractures of the Forearm with Special Reference to the Anterior Monteggia Fracture"; Mr. W. B. Foley on "Ischio-femoral Arthrodesis of the Hip by Posterior Open Approach" (film).

International Congress on Rheumatic Diseases

Among the speakers at the International Congress on Rheumatic Diseases to be held in New York on May 30-June 3 will be Lord Horder on "Rheumatism, a National Problem," and Dr. William Tegner on "Some Aspects of Psychogenic Rheumatism."

International Hospital Congress

The International Hospital Federation will hold its first International Hospital Congress in Holland at Amsterdam and Groningen on May 30-June 4. The design of hospitals and the training and duties of hospital administrators are among the subjects to be discussed. Further particulars may be obtained from Captain J. E. Stone, King Edward's Hospital Fund for London, 10, Old Jewry, London, E.C.2.

SOCIETIES AND LECTURES**Monday**

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W.—April 11, 8.30 p.m., Discussion: "*Acute Cholecystitis*," to be introduced by Dr. E. R. Cullinan and Mr. Guy Blackburn.

Tuesday

MIDDLESEX COUNTY MEDICAL SOCIETY.—At West Middlesex Hospital, Isleworth, April 12, 2.45 p.m., general meeting.

Wednesday

SOCIETY OF CHEMICAL INDUSTRY: FOOD GROUP.—At Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W., April 13, 6.30 p.m., 18th annual general meeting "*Some Thoughts on the Food Group*," by Dr. E. B. Hughes.

APPOINTMENTS

BURN, A. TELFORD, M.B., B.S., D.P.H., Medical Officer of Health for the Borough of Sale and the Urban District of Lymm, and Divisional Medical Officer to the Cheshire County Council

NEWNS, G. H., M.D., M.R.C.P., Dean of the Institute of Child Health, University of London, in succession to Dr. W. G. Wyllie, who has resigned.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Ashwell.—On March 20, 1949, at The Willows Nursing Home, Bramley, Leeds, to Evelyn (née Hogg) wife of Dr. Colin S. Ashwell, Sharlston Common Wakefield twin daughters (premature)—Elizabeth and Susan

Whalley.—On March 21, 1949 to Dr. Annette Whalley (née Brooks), wife of Dr. Hugh Whalley, 21, Burton Crescent, Leeds, a son

MARRIAGE

avelock.—Buck. —On March 19, 1949, at Ealing Methodist Church, Brian J. R. Havelock to Joyce M. Buck, M.B., B.S.

DEATHS

Armstrong.—On March 28, 1949, at Royal Free Hospital, London, W.C., Kathleen Jane Armstrong, M.R.C.S., L.R.C.P.

Brown.—On March 24, 1949, at Pau, B.P., France, Francis Leonard Brown, M.D., aged 84

Brown.—On March 22, 1949, at Ramsgate, John Brown, M.R.C.S., L.R.C.P. formerly of Flixton and North Wales

Budden.—On March 25, 1949, at Staneside, Roman Road, Dorking, Tice Fisher Budden, M.D., aged 82

Cawston.—On March 19, 1949, at 345, Vause Road, Durban, Natal, South Africa, Frederick Gordon Cawston, M.D.

Clayton.—On March 21, 1949, Thomas Morrison Clayton, M.D., D.P.H., of Gateshead

Coates.—On March 23, 1949, at 22, College Gardens, Belfast, Foster Coates, M.D., D.P.H., aged 67

Fagge.—On March 26, 1949, at the War Memorial Hospital, Melton Mowbray, Robert Hilton Fagge, M.R.C.S., L.R.C.P., J.P., aged 77

Fraser.—On March 27, 1949, John Henry Pearson Fraser, D.S.O., M.C., M.B., B.Ch., of Jersey previously of Southampton, aged 76

Green.—On March 26, 1949, at 22, Church Street, Prescott, Lancs, Samuel Morris Green, M.R.C.S., L.R.C.P., D.P.H., aged 72

Hill.—On March 9, 1949, James Lorimer Hill, M.B., B.Ch., D.P.H.

Legge.—On March 26, 1949, as the result of an accident, Sydney Buxton Legge, M.D., J.P.

Pennfather.—On March 25, 1949, at 79, Portwood Road, Southampton, Victor Dam and Pennfather, M.R.C.S., L.R.C.P.

Stoker.—On March 21, 1949, at Guy's Hospital, London, S.E., George Morris Stoker, M.R.C.S., L.R.C.P., of 7, Sireatham Road, Mitcham, Surrey, aged 50

Thambiah.—On Feb. 18, 1949, Rao Bahadur Capt. Saravanamuttu Thambiah, M.C., F.R.C.P.Ed., D.T.M.&H., F.D.S.

Thomas.—On March 22, 1949, at Brampton Kinlet, Canford Cliffs, Bourne-mouth, Frank Griffith Thomas, M.B., B.Ch., late of Maccs-yr-Haf, Swansea, aged 76

Ward.—On March 23, 1949, suddenly, while walking home, George Stafford Ward, M.B., B.S., of 12a, Malford Court, London, E.

West-Watson.—On March 20, 1949, at Victor Lodge, Manningham, Bradford, William Norman West-Watson, M.D.

Wood.—On March 27, 1949, at 684, Lordship Lane, Wood Green, London, N., Frederic Charles Wood, L.M.S.S.A., D.P.H., aged 83

Young.—On March 24, 1949, Harold Godfrey Young, M.B., B.Ch., of North Golding, St. Albans Road, Hatfield, Herts

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pethidine, "Trilene," and Chloroform in Labour

Q.—I have found that pethidine by injection, followed by "trilene" given with a Freedman inhaler, is not sufficient in every labour to overcome the pain during birth of the head. Is it safe to follow pethidine and trilene with a small amount of chloroform?

A.—Pethidine is an antispasmodic and analgesic drug which has proved valuable in relieving pain and aiding relaxation in the early stages of labour. Its great advantage is that there is little if any effect in depressing respiration in the baby. Trilene, or trichloroethylene, is similar in its action to chloroform and the two are not incompatible. There is thus no reason why pethidine and trilene should not be combined with a small amount of chloroform during the birth of the head; this combination should be perfectly safe provided only small amounts of both trilene and chloroform are used.

The Royal College of Obstetricians and Gynaecologists, in its report on trilene as an analgesic for childbirth, was unable to recommend that midwives working alone should give trilene through the Freedman inhaler, which was used in the extensive trials on which the report is based. The chief risk is of overdosage; it is shown in the report that shaking the bottle or a rise in temperature in the room causes a great increase in the amount of trilene received by the mother, and that there is consequently a real danger of overdosage and of the occurrence of surgical anaesthesia. These facts should be borne in mind when using trilene for analgesia in midwifery. It is important not to allow a too prolonged use of the Freedman inhaler and to see that overdosage does not occur. For some comment on the report of the Royal College of Obstetricians and Gynaecologists see *Journal*, March 26, p. 537.

Effect of Flying on Pneumothorax

Q.—A patient who had an artificial pneumothorax induced nine months ago wishes to fly to South Africa. Are there any contraindications, and should any special precautions be taken?

A.—When a patient with an artificial pneumothorax ascends to high altitudes he may become short of breath owing to the increase in volume of the air in the enclosed space of the pleural cavity which occurs as the atmospheric pressure is reduced. It is therefore advisable for such a patient to undertake the journey by air just before a refill is due, and to arrange for another refill as soon as possible after reaching his destination. From the work of Todd and of Lovelace and Hinshaw it may be stated that flying by persons with a pneumothorax should be discouraged until the lesion is reasonably quiescent. Where patients have to make frequent journeys by air, any pleural adhesion that is likely to rupture should be divided and a reasonable time allowed to elapse before the flight is made. It is difficult to state the height to which a patient may fly with safety, but as a general rule it is wise not to exceed 6,000 ft. (1,800 metres), for it should be remembered that 1,000 ml. of air saturated with water vapour at 37° C. at sea level will become 1,500 ml. at an altitude of 10,000 ft. (3,000 metres). Allowance must be made for this change in volume if it is essential for a patient with a pneumothorax to travel by air.

Tender Swellings of the Heel

Q.—What is the treatment for the painful gross thickening of the skin and subcutaneous tissues behind the heel seen in so many young women? What are the faults in the ready-made shoes which cause them?

A.—These tender swellings behind the heel are usually due to inflammatory changes in and around an adventitious bursa behind the tendo Achillis, or in the bursa which is normally present between the tendo Achillis and the os calcis. The inflammatory changes result from friction of the tissues against

the shoe. In some cases there is a circulatory element in the aetiology, for the condition tends to be more troublesome in winter and is often associated with chilblains and allied disorders. In other cases there may be an irregular bony prominence at the posterior aspect of the os calcis which aggravates the trauma arising from friction. The faults attributed to ready-made shoes probably lie in the selection of size and fitting rather than in the design itself. Nevertheless there is sometimes a tendency for the back of the shoe to curve forwards rather too much at the top. This may lead to friction against the tendo Achillis during the flexion-extension movements of the ankle which occur during walking, for with each contraction of the calf muscles the tendon becomes tightened like a bow-string and is pressed backwards against the top of the shoe. Treatment should be conservative in the first instance: the principle is to relieve the friction caused by the shoe. This may be achieved by the use of protective pads of felt applied over the swelling; by raising the affected area of the heel above the shoe by means of a "sorbo" rubber pad beneath the heel; or by the wearing of soft-backed or cut-away shoes. These measures are usually adequate for the acute or subacute type of case; but, if the symptoms are chronic and persistently troublesome, operative treatment may be advisable. This consists in removal of the affected bursa, combined where necessary with trimming of the underlying bony prominence.

Treatment of Superficial Burns

Q.—What is the most satisfactory treatment for superficial body burns in children with or without the formation of blisters? These often give much trouble through infection, although they cannot be considered serious enough for hospital treatment, especially in a widely scattered rural practice.

A.—The difficulty about superficial body burns in children is almost entirely one of effectively and continuously covering them during the ten days or so required for healing. Without plenty of crêpe bandages, supplemented by thin strips of surgical strapping (or, better, a thin shell of plaster-of-Paris over the bandages), it is almost inevitable that such burns will become infected if blisters form—whatever the local application. Assuming that crêpe bandages and strapping are available, the burn should be first cleaned by gentle rubbing with cotton-wool soaked in 1% "cetavlon" solution, or soap and sterile water, then dried, smeared with penicillin cream (200 or 100 units per gramme) or with sulphamylamide cream, and covered with gauze and wool. If these dressings remain intact they should not be touched for ten days. If crêpe bandages are not available, and if the burn is not very large and is truly superficial, it will probably do best if the surface is dried up with tannic acid or silver nitrate; but this treatment should not be used if there is any doubt about the depth of the burning. Whatever treatment is adopted, the doctor or nurse should first put on a face-mask and should carefully wash his or her hands.

Deep X Rays for Oat-cell Carcinoma of Lung

Q.—Would deep x-ray therapy help in an advanced inoperable case of oat-cell carcinoma of the lung in a middle-aged man? If this is inadvisable, is any alternative treatment available?

A.—There is considerable disagreement among radiotherapists about the value of deep x-ray therapy in an advanced case of oat-cell carcinoma of the lung. In the writer's opinion, in all except the most advanced cases palliative x-ray therapy should be attempted, and is often useful, especially to relieve pain. In a case such as this the radiotherapy should be planned as palliative, and it usually seems to be unwise to attempt radical x-ray therapy. Palliative x-ray treatment does not increase the length of survival, but clinically there can be no doubt of its usefulness in a substantial proportion of cases.

With regard to alternative therapy, the use of bis-nitrogen mustard by intravenous injection is sometimes of limited palliative value, especially in the more advanced cases, but it has the disadvantage of toxicity and the beneficial effects are very short-lived. The usual unit dose is 0.1 mg. per kilo of body weight, given in 10 ml. of normal saline intravenously, particular care being taken not to allow any solution to escape outside the vein. The best plan of dosage appears to be three or four unit doses on alternate days. It is desirable to arrange for daily blood counts

during the course of injections, and then less frequently for the following four weeks. It is important to watch the haemoglobin concentration and the absolute lymphocyte count.

Auricular Fibrillation in the Elderly

Q.—What is the best treatment for paroxysmal auricular fibrillation in a man of 64? Radiographs of the heart show no enlargement or disease, and the blood pressure is normal. The attacks are very incapacitating, although between them he is well.

A.—Thyrotoxicosis must be excluded first, and this may not be easy. A specialist's opinion should be obtained. If it is reasonably certain that there is no known organic disease underlying the rhythm change, and if the nature of the rhythm change has been established as auricular fibrillation by electrocardiography, the only drug likely to prevent attacks is quinidine 3 to 5 gr. (0.2 to 0.32 g.) three times a day indefinitely. Auricular fibrillation in elderly subjects without apparent cause generally becomes persistent, and finally resists efforts to restore normal rhythm by means of quinidine. In such cases the condition is often best stabilized when permanent auricular fibrillation is accepted, and treated with a maintenance dose of digitalis if the ventricular rate is rapid, or left untreated if it is below 90.

Duration of Psycho-analysis

Q.—Can you inform me if there is any recognized time limit for psycho-analysis? For example, if a stammer has been cured by this after, say, five years, may not continued treatment tend to foment introspection and a too great reliance on the psycho-analyst?

A.—There is no specific time limit for psycho-analysis, and the extent of treatment depends on what is aimed at. The mere abolition of the symptom is often a simple process, and in some cases this is enough to break a vicious circle—for instance, in the case of a paralysed "shell-shocked" man whose paralysis is an unconscious desire to get out of the fighting but persists long after the war because it has produced a morbid autosuggestion that he cannot walk. If, therefore, he is made to walk by whatever means (persuasion, suggestion, or analysis), this may be sufficient to break the vicious circle, to abolish the morbid autosuggestion, and to fit the patient for ordinary civilian life. But it has to be remembered that the symptom is only an indication that there is something wrong with the personality and the patient's attitude towards life; in many cases, unless this is rectified, the patient is still ill adjusted and may relapse. That is why, even after the symptom is abolished, the analyst as a rule strives to produce a radical change in the individual's personality, so that he not only has no symptoms but is mentally healthy and capable of meeting all his responsibilities happily. In other words, the aim of treatment is not merely to abolish the symptom but to cure the morbid attitude in the personality which caused it and restore the patient to complete health. At the same time common sense must be brought to bear on the whole business. From one point of view the patient could be submitted to analysis all his life, as there are always residues of ill adjustment that might be corrected; not only so, but there are rare cases in which the individual prefers to wallow in his emotional state, and it is for the analyst to determine whether this is the case. The patient is of course not well so long as he is doing this, but merely to allow him to continue is not helping towards cure. The questioner would be well advised to seek for information from the psycho-analyst about the precise situation in the case he has in mind.

I.D.E. Test for Syphilis

Q.—May I have details of the I.D.E. test used by the Nigerian Medical Services for the diagnosis of syphilis?

A.—The I.D.E. test as originally described (*J. Lab. clin. Med.*, 1936, 21, 1190) is carried out as follows:

To prepare the antigen, beef heart freed from fat, fibrous tissue, and blood vessels is finely minced, and 20 g. of this are mixed with 100 ml. of 95% alcohol and kept in a corked container in a water-bath at 60° C. for seven weeks; the mixture is shaken twice a day and finally cooled, filtered, and kept in a dark place. Fluid I is prepared by adding 0.2 g. of cholesterol to 10 ml. of this stock solution and warming for 10 minutes at 56° C.; Fluid II consists of

5% gum benzoin dissolved in the stock solution; Fluid III is a 1% alcoholic solution of crystal violet; and Fluid IV is a 1% alcoholic solution of azure II. For use in the test 100 ml. of Fluid I are added to 5 ml. of Fluid II and mixed; 1 ml. of Fluid III and 1 ml. of Fluid IV are mixed and 1 ml. of the resultant solution is added to the mixture of Fluids I and II. This constitutes the antigen. To carry out the test, place one drop (approximately 0.03 ml.) of the patient's blood in the concavity of a hollow slide, add one drop (0.05 ml.) of 3.5% saline and stir well, spreading it all over the surface of the depression. Prepare diluted antigen by adding 0.6 ml. of 2.5% saline to 0.2 ml. of the antigen, mix thoroughly by shaking, and add one drop (0.03 ml.) to the blood-saline mixture on the slide; place the slide on a flat surface and rotate vigorously for 3 to 4 minutes. The reaction is read by means of a microscope with a magnification of about 50, the examination being directed towards the periphery of the hollow in the slide: a positive reaction is indicated by purplish-blue-coloured clumps, the size of which is roughly proportional to the strength of the reaction. The slide should be covered with a slip and the reading carried out within 15 minutes.

Various workers have from time to time introduced modifications of the test. Thus, Rein and Hazay (*J. Lab. clin. Med.*, 1938, 23, 954) found that the test was more sensitive if sera were heated; they used paraffin-ringed slides in preference to those with hollow depressions, and stated that 8 minutes was the optimum time for rotation. Timms (*E. Afr. med. J.*, 1945, 22, 27) points out that, owing to evaporation in a hot climate, it is necessary to cover the preparation before shaking, and advises fixing the cover-slip with petroleum jelly or a rubber band. Presumably this precaution would be necessary in Nigeria.

Disseminated Sclerosis and Vaccination

Q.—A patient with disseminated sclerosis was recently successfully vaccinated. This has been followed by a severe flare-up of her condition, so that she is unable to use a cup or even walk unaided. Is there any connexion between the two, and is there any drug which will alleviate her symptoms?

A.—Exacerbations of disseminated sclerosis are likely to follow any acute systemic disorder, and they are known to be precipitated by injections of foreign proteins, particularly if these give rise to generalized disturbance. There is, however, no known connexion between the virus of vaccinia and disseminated sclerosis. The best way to help a relapse of this sort is to secure absolute rest in bed until recovery starts and then to institute re-education exercises.

Allergy to Fluorescent Light?

Q.—Is there any evidence that allergy to fluorescent lighting exists? I have a patient who for the past 18 months has developed an urticarial rash after exposure to fluorescent lighting; she is free from it when she has not been so exposed.

A.—The writer knows of no reference to urticaria from fluorescent lighting. Allergic urticarial reactions may follow exposure to ordinary daylight; it is, of course, localized to exposed parts. The light from fluorescent lamps shows a similar spectrum with some emphasis of the mercury lines (the source being mercury vapour) and some near ultra-violet radiation. A patient sensitive to such light in a physical sense should be sensitive to normal daylight.

Ectopic Gestation and Future Pregnancy

Q.—A patient aged 30, with one child of 3½ years, had an operation for ectopic pregnancy three years ago. She now wants another child. (a) What are the best instructions to give her? (b) Are vitamin E or the hormones useful, and if so in what dosage? (c) What are the chances of conception? The other tube and ovary were normal when examined after the operation.

A.—It is not clear from the question whether the recent relative sterility has been voluntary or involuntary. If the former, no special advice other than to practise coitus during the fertile period seems necessary. If, however, the patient has tried and failed to conceive, there is nothing in the history to indicate treatment with either vitamin E or hormones. Full investigation should be carried out; hysterosalpingography is especially important, for the tubal factor is likely to be concerned in the lowered fertility. The previous occurrence of tubal pregnancy (it is assumed that it was tubal in site and

that salpingectomy was carried out) is itself evidence of disturbed tubal function, and the remaining tube may well be abnormal. Even if it is not, the removal of one tube lowers the chances of pregnancy by approximately one-half. When an ovum is produced by the ovary on the side of the previous operation (and this is likely to occur, on the average, during half the cycles), it can be fertilized and implanted only if it undergoes external migration. If, however, the ovary as well as the tube was removed at the previous operation the chances of pregnancy should be somewhat higher, because ovulation must then always take place in the ovary whose oviduct remains intact. For one reason or another only about 35% of women conceive again after once having an ectopic pregnancy. In the event of another pregnancy taking place the risk of its again being ectopic has been estimated at 1 in 10.

Psoriasis and Stilboestrol

Q.—I have read an article on the treatment of psoriasis by stilboestrol. Is this a good method?

A.—This is not a good treatment and has no rational basis, and should therefore not be employed. Endocrine factors sometimes enter into the aetiology of a particular case of psoriasis or a particular phase or type of eruption, as in menopausal cases. The indications for treatment and dosage then follow general lines.

NOTES AND COMMENTS

Deafness and Tinnitus.—Mr. W. H. B. MAGAURAN (London, W.1) writes: The answer to the question on deafness and tinnitus (Feb. 26, p. 378) gives the impression that labyrinthine fenestration is of little value in the relief of tinnitus in otosclerosis. This is not my experience, as I find that, if highly neurotic patients are excluded from operation, the prospect of the relief of tinnitus is good in otherwise suitable cases. Indeed, I have had cases of otosclerosis with fairly marked nerve deafness where troublesome tinnitus has been relieved by operation. The relief of a distracting tinnitus will, of course, in itself help the hearing. I have found that the relief of tinnitus, when it takes place, usually occurs soon after operation, but in rare cases it may be delayed for months.

As regards the relief of deafness, the answer given is that in many cases the restored hearing is lost from closure of the new fenestra or from serous labyrinthitis. I have found, however, that many cases retain the restored hearing; but in the event of the fenestra closing it can be readily re-established, at another operation, with restoration of the improved hearing. For example, one of my patients, in whose case the fenestra closed within a few months, has now excellent hearing a year after the re-establishment of the fenestra. Healing after such a reopening takes place in much less time than after the original operation, and I have noted that there is less vertigo.

The serous labyrinthitis mentioned is in my opinion caused by traumatic labyrinthitis, due to instrumentation or pressure of the dressing. This is not frequent in my experience, and its incidence should lessen in frequency as the skill and experience of the surgeon improve. The fact that the operation, in skilled hands must be one of the safest in major surgery is also worthy of mention.

Calculi in a Paraplegic.—Mr. NORMAN GIBBON (Liverpool) writes: In your answer to the question on calculi in a paraplegic ("Any Questions?" Feb. 26, p. 377) you recommend the regular use of ammonium chloride to acidify the urine. I think it worth while to point out that this substance increases the urinary calcium output so that the solubility of the calcium salts may not be increased. On the other hand it has recently been shown by Cordonnier and Talbot (*J. Urol.*, 1948, 60, 316) that the oral administration of acid sodium phosphate (5.8 g. a day) to such cases reduces the urinary output of calcium by about 50%, in addition to lowering the pH. It would seem that this is the drug of choice in these cases.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 9 1949

THE SECRETARY REPORTS

COMPLAINTS

There is an elaborate disciplinary code under the new Service for dealing with complaints by patients against their doctors. But there is no reciprocal procedure such as that which obtained under the N.H.I. to enable a doctor to raise questions as to the conduct of a patient while under treatment. The Service Committees and Tribunal Regulations, 1948, require that any complaint by a person against a medical practitioner in respect of an alleged failure to comply with the terms of service shall be investigated by the Medical Service Committee. The Regulations, however, contain no such provision as appeared in the Medical Benefit Regulations under the National Health Insurance Act, 1936, requiring any question arising between an insurance practitioner and a person . . . in respect of the conduct of the person while receiving treatment . . . to be investigated by the Medical Services Subcommittee. Indeed, the matter goes somewhat deeper. In National Health Insurance laws there were rules for the conduct of insured persons printed on the medical card. One rule was that the patient "shall not make unreasonable demands upon the professional services of the practitioner attending him." Another was that the patient "shall not summon the practitioner to visit him between the hours of 8 p.m. and 8 a.m., except in cases of serious emergency." Another was to the effect that, where the circumstances of the case permit, the practitioner should be informed before 10 a.m. on the day on which the visit is required. There are no such rules on the modern medical card. In their place advice is given under the heading of general information: "Please do not ask the doctor to call unless the patient is too ill to attend his surgery"; "Please do not call in the doctor between the hours of 8 p.m. and 8 a.m. unless you really need him." Presumably the absence of penalties follows from the substitution of gentle advice for explicit rules. In this modern age when so much stress is laid on equality of treatment it would appear reasonable that as the doctor, under risk of penalties, has to observe rules, so the patient, also under risk of penalties, should be similarly required to observe rules to govern his conduct in relation to his doctor.

Removal from the Medical List

Another curious omission in the Act is the lack of any provision for removing from the list of a local executive council the name of a doctor who is no longer working in the area. Enormous trouble has been taken to regulate entry to the medical list. The new entrant must apply for permission to enter his chosen area and he must obtain consent from various official bodies. But those who framed the Act seem to have overlooked the question of a doctor's removal from the list. It is true that a doctor may remove himself. He may also be struck off if the disciplinary tribunal feels that his continued inclusion would be prejudicial to the efficiency of the Service. But there is no provision by which the name of a doctor who, say, has moved without notifying his move can be removed from a list. This point also has been submitted to the Minister for inclusion in the amending legislation.

Medical Staffs of Transferred Hospitals

One is frequently hearing of anxiety among specialists on the staff of hospitals involved in "change-of-user" proposals. Within the past few weeks this office has been approached by the staffs of four hospitals, each of which is in association with a teaching hospital, and in each case the teaching hospital desires not to take over the staff of the smaller hospital in its entirety. There is involved here a principle of substantial importance. It is worth repeating what the Minister expressly undertook, in relation to the staffs of hospitals taken over on the appointed day—that the boards "will offer new appointments to their staffs either in their existing or other hospitals, which they will be free to accept or refuse as they will." The straightforward interpretation of this undertaking, which formed part of the Minister's replies to the B.M.A. in April, 1948, is that the onus lies with the boards to offer other appointments. We should be glad to be informed of any similar difficulties arising in different parts of the country.

The Armed Forces and the Colonial Medical Service

The repercussions of the Spens Reports are only just beginning. The first-fruits, which may perhaps be regarded as not quite ripe, have been seen in the professorial field. An effort to bring forth fruit is being made by the Association in the public health field. Others are now beginning in the no less important field of the armed Forces and the Colonial Medical Service. The Annual Report of the Council, published in last week's *Journal*, includes detailed recommendations which have now been made to the Services and to the Colonial Office to secure the appropriate application of the Spens standards to medical officers in the Services and the Colonial Medical Service. There are other groups remaining to be considered, including the medical officers in the Civil Service and the administrative medical officers of regional hospital boards. It may be a long job, but it is the Association's clear duty and intention to press for the revision of rates of remuneration in all organized medical services so as to bring them into line with the Spens Reports.

Dental Anaesthetics

The recent decision of the Minister to impose a 50% cut in the gross remuneration of dental practitioners whose earnings exceed £4,800 a year has not been without its repercussions. The Association has learnt that here and there dental practitioners are dispensing with the services of the general practitioners who formerly gave dental anaesthetics for them and are administering the anaesthetic themselves or undertaking extractions under local analgesia. The reason is that the fees for these services are included in the dentists' gross remuneration, now subject to a ceiling.

The General Medical Services Committee, believing that it is detrimental to the dental services of medical practitioners should be able for the giving of dental anaesthetics, the Department that in computing the gross fees paid to practitioners for anaesthetics in dental cases should not be

National Health Service

GENERAL PRACTITIONERS AND HOSPITAL WORK

The Council has set up a joint committee, composed of representatives of the Central Consultants and Specialists, General Medical Services, Health Centre, Private Practice, and Public Health Committees, to consider the question of the association of general practitioners with hospital work, for a new position has arisen under the National Health Service Act. At its first meeting on March 22 the committee considered the problems generally and agreed that there is a danger of a division between the hospital consultant and the general practitioner which is bad for the profession as a whole and would operate to the disadvantage of the patient.

The Joint Committee recognizes the difficulties in formulating policy on this matter, which will affect the future relation of general practitioners with the teaching of medicine and hospital work generally. It attaches great importance to the representation of the views of consultants and specialists on the subject and has invited the Central Consultants and Specialists Committee to appoint to the Joint Committee such members as will adequately cover the whole field of consultant and specialist practice. The Central Consultants and Specialists Committee has accordingly increased its representation on the Joint Committee from three members to six.

Membership of the Committee is as follows: Mr. A. Staveley Gough (Watford), part-time consultant (chairman); Mr. A. Lawrence Abel (London), senior surgeon, Princess Beatrice Hospital, surgeon, Royal Cancer Hospital; Dr. A. Beauchamp (Birmingham), general practitioner; Dr. James Fenton (London), medical officer of health; Dr. E. W. Goodwin (Leicester), general practitioner; Dr. T. Rowland Hill (London), consulting neurologist; Dr. D. F. Hutchinson (London), general practitioner; Dr. R. H. H. Jolly (Wolverhampton), medical officer of health; Dr. C. F. R. Killick (Williton, Somerset), general practitioner; Mr. G. Lowe (Tiverton), general practitioner; Mr. O. E. J. McOustra (Cheltenham), honorary surgeon and surgeon, Genito-Urinary Department, Cheltenham General Hospital; Mr. R. L. Newell (Manchester), honorary consulting surgeon, Manchester and Salford Hospital for Diseases of the Skin; Dr. Wyndham Parker (Worcester), medical officer of health; Dr. A. Talbot Rogers (Bromley), general practitioner; Mr. N. Ross Smith (Bournemouth), orthopaedic surgeon, Royal Victoria and W. Hants Hospital; Dr. H. H. D. Sutherland (London), general practitioner; Dr. S. Wand (Birmingham), general practitioner; Dr. E. C. Warner (London), physician, Charing Cross Hospital.

WAGES OF MANUAL WORKERS

The average weekly earnings of manual wage-earners employed in manufacturing industries generally and in a number of the principal non-manufacturing industries were in October, 1948, about double what they were in October, 1938. This is shown by investigations carried out by the Ministry of Labour, the results of which were published in the *Ministry of Labour Gazette* for March, 1949. The following Table shows a comparison between the average weekly earnings of various groups of manual workers for the two months cited, and the percentage increase for each group.

Average Weekly Earnings

	1938	1948	% Increase
Men 21 and over ..	69s. 0d.	137s. 11d.	100
Youths and boys ..	26s. 1d.	58s. 9d.	125
Women 18 and over ..	32s. 6d.	74s. 6d.	129
Girls ..	18s. 6d.	49s. 5d.	167
All workers ..	53s. 3d.	117s. 4d.	120

The wages shown are gross earnings before deductions are made for income tax or contributions to the national insurance schemes. The hourly earnings are rather higher because fewer hours a week were worked in 1948 than in 1938. The percentage increase of average hourly earnings was as follows: men, 104; youths and boys, 136; women, 140; girls, 182; all workers, 126.

Figures for the increased earnings of professional men and women are not available for 1948, though rough figures for 1946 for some professions were given in the *Supplement* of Nov. 27, 1948 (p. 192). The betterment factor at present being used by the Government in the remuneration of general practitioners in the Service gives an increase of 34% over pre-war gross remuneration.

JOINT TUBERCULOSIS COUNCIL

At the last meeting of the Joint Tuberculosis Council the position of tuberculosis medical staffs in the National Health Service was again discussed, and the council decided to seek an interview with the Ministry of Health in the hope of obtaining some clarification of the Ministry's proposals on the future status of tuberculosis officers and sanatorium superintendents. The council also decided to press strongly upon the Ministry of Health the need for appointing or co-opting on to the Standing Tuberculosis Advisory Committee a representative of the tuberculosis services engaged in field work.

The council also considered the draft of a Memorandum on the Notification of Tuberculosis which had been prepared with a view to its issue to the medical profession by the Ministry of Health. The council felt that the memorandum as drafted would not bring about the desired improvements in notification, and asked the new Standing Advisory Committee on Tuberculosis to consider the whole question, including the council's previously published report advocating two separate stages—i.e., intimation and notification.

Dr. Peter W. Edwards was elected chairman of the council in succession to Dr. D. P. Sutherland.

FACULTY OF OPHTHALMOLOGISTS

The Honorary Secretary reports that at the Council meeting on Feb. 18 the reduction of the fee from £1 11s. 6d. to £1 5s. as from April 1 (*Supplement*, Feb. 26, p. 92) was discussed. It was decided that the Negotiating Committee should be urged to protest against the reduction, and that each individual member of the Faculty should receive a copy of the Minister's letter with a letter explaining the position.

It was decided to send a circular letter to the senior administrative medical officers of regional hospital boards urging them to set up ophthalmic advisory committees if they had not already done so, and giving an outline of the constitution of such a committee. It was further arranged that representatives of the Faculty should call upon the senior administrative medical officers of regional hospital boards and explain any points if necessary.

There were many points in the memorandum from the Joint Emergency Committee (Optical Profession) on the Ministry of Health directive, H.M.C.(48)63, B.G.(48)66, to which the Council took exception, notably those arising out of the assumption that the report of the joint subcommittee of the Faculty and the Joint Emergency Committee represented the views of the Faculty, when in fact the Council had repudiated the report. The Honorary Secretary was instructed to write to this effect to the senior administrative medical officers of the regional hospital boards and to the secretary of the Joint Emergency Committee (Optical Profession), and to inform the Ministry that he had done so.

The Council felt that no action could be taken in the matter of priority prescriptions for glasses in view of the fact that the machines in the country were already working to capacity.

Mr. Law reported that the Ministry was interested in the question of corneal-graft donors and would be glad to meet representative members to discuss the situation. The following were appointed: Mr. R. C. Davenport, Mr. J. H. Doggart, and Mr. A. Lister.

British Medical Association

SPECIAL REPRESENTATIVE MEETING

Wednesday, March 30, 1949

FORMATION OF BRITISH MEDICAL GUILD APPROVED

Special Representative Meeting of the Association was held March 30 at B.M.A. House, London, to consider the constitutional position of the Association. This was a separate meeting from the one which had taken place on the previous day on the question of remuneration, the proceedings of which were reported in the *Supplement* of April 2 (p. 209). Dr. E. A. Gg again presided.

Before the main business came forward Dr. John Etheridge (Morpeth) asked that it be made plain by resolution of the meeting "that the fear of an injunction against the B.M.A. should be ignored." This was seconded by Dr. J. Ewart Purves (Milebury), and supported by Dr. E. C. Warner (Marylebone). Dr. A. V. Russell (Wolverhampton). The last-named said the profession was in a stronger position than it was a year ago, and he very much doubted whether any Government would go to the length of applying for an injunction against the Association; even if it did he could not conceive anything so likely to unite the profession or to gain the support of the public.

Dr. Frank Gray (London) said that the Representative Body had always shown a sense of responsibility. Here was a motion which asked, before the business for which the meeting was called had been taken, before any arguments had been considered, that the question of an injunction should be put on one side. It was the most reckless and irresponsible proceeding.

He was amazed that a succession of speakers should have come to the platform and have said, "Don't worry about an injunction. Say you are not afraid of it, and it does not matter." Apart from any actual risk of injunction, it had a serious effect to have this threat hanging over them all time. He hoped that this proposal would be turned down. Dr. J. A. Gorsky (Westminster and Holborn) asked the meeting to turn this down without further discussion. To be a list was not to lack courage. There was grave risk of an injunction if they went on as they had done. The Chairman of Council said that fear had nothing to do with the proceedings to-day. They were there to take sensible precautions on certain points.

Dr. Etheridge, the mover, replied that the motion had been brought forward in the most responsible manner. That this had existed in the past could not be denied. The resolution was overwhelmingly defeated.

Need for a New Organization

Dr. H. Guy Dain, Chairman of Council, then presented a report of the Council on the constitutional position (*Supplement*, Feb. 26, p. 95), and moved the following recommendation:

That for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, a new organization be established in the form of an independent board of trustees with power to organize and finance collective action by the profession and to provide financial compensation to practitioners suffering financial hardship through participation in such collective action;

That the new organization be entitled the British Medical Guild; That the new organization be constituted in accordance with the deed as drafted by the Association's solicitors."

Dr. Dain said that the present meeting was a consequence of the proceedings of the last Annual Representative Meeting, at which a number of resolutions were on the agenda designed to strengthen the Association's hands in undertaking collective bargaining. The Council appointed a Constitution Committee which had gone into the possibilities with great care. There were two features of the present constitution which were source of danger to effective action. These arose from uses 3 and 4 of the Memorandum of Association, which were

compulsorily inserted by the Board of Trade. The Association had not the protection afforded to a trade union and could not use its funds to support members who suffered for their adherence to its policy. It was found to be impossible to change the present constitution of the Association into a trade union without winding it up, distributing the assets among the members, and starting afresh. That would be a very unwise step to take. Was it possible, then, to establish another trade union by the side of the Association? On considering the powers of a trade union as such it was found that great legal doubt existed as to the possibility of a trade union of doctors proving effective in a time of struggle.

There were two trade unions of doctors already registered, but the test of their efficiency in collective bargaining had never been made. A trade union must consist of workmen or masters combined for trade protection purposes, and there was a difference of opinion among lawyers whether doctors could be considered either masters or workmen. They had been advised that a doctors' trade union would not get the protection of the Trade Disputes Act, because they would not be defined legally as workmen. The Medical Practitioners' Union was advised by counsel that it had that protection. On hearing this the Council took further counsel's opinion, which confirmed the original opinion given to the Association. Following this a meeting was arranged between the Association's counsel and the counsel of the Medical Practitioners' Union, but each counsel reaffirmed his original opinion, so this was a matter of the opinion of one or more eminent counsel against eminent counsel on the other side. On looking at the problem of trade unionism the Council decided first of all that the Association would not be turned into such a union, and that even if it could it was doubtful whether it would afford the protection which a workmen's trade union possessed under the Trade Disputes Act.

In the early days when the Insurance Acts Committee was established a National Defence Fund was formed, and with that example in front of them the Council looked to see whether any better method could be devised. The Council was now offering a set of proposals for a Guild on the lines of the National Insurance Defence Trust. They had looked into the question of creating by the side of the B.M.A. a parallel organization with membership, but such a body would have power only to protect its own members, and what was wanted was an organization which could protect all the doctors engaged in the Service, whether members of any particular body or not. There were, of course, a great many members of the Association who would be completely opposed to the establishment of a trade union and, for good reasons in their own cases, would refuse to join. It was proposed that the British Medical Guild should not have a membership but should proceed by means of trustees centrally appointed who would hold the funds of the Guild and carry out its policy. He understood that if proper care were taken in the election of the trustees of the Guild, if they were separately appointed and the organization was separately run by its own officers, paying its own expenses, even if the trustees might be members of the Council or of executives of the Divisions, the capacity of the Guild for action would not be invalidated.

The general practitioners working the National Insurance Act had had a Defence Fund established for many years, and it was now for other branches of the profession in the National Health Service to make similar arrangements to enable funds to be created to cover all those engaged. There would be no question of a practitioner subscribing twice, once to the existing Defence Fund and once to the Guild; practitioners who had been subscribing to the Defence Fund would continue to do so and the trustees of that fund would make the money available to the Guild when need arose. For the rest it would be necessary to set up machinery for collecting money, and that problem had been referred to the appropriate committees of the Association for their consideration.

Supposing a trade union of doctors were properly constituted and found to be effective under the Trade Disputes Act, what, after all, would the trade union be able to do that the Guild could not do? A trade union was protected against action against itself or its members for anything done in the course of a dispute which might be considered in restraint of trade. They

in the profession, however, were not interested in the "closed shop"; their policy had been against the "closed shop" principle, and he hoped it always would be.

Dr. D. L. S. Johnston asked whether it was possible legally to pass over the National Defence Fund to another fund which might be established.

Dr. Dain said that the trustees of the Defence Fund were not inhibited by the same difficulties as the Council or its committees. The money would remain in the hands of the trustees of the Fund, with the same freedom to act as they had always possessed, and they would, as he assumed, act in concert with any body formed for the protection of general practitioners in any conflict that might arise.

Rejection Moved

Several motions were on the agenda expressing the view that the British Medical Association as at present constituted is competent to undertake any necessary negotiations, and calling for the abandonment of the Council's proposal. Others asked that owing to the conflict of legal opinion the matter should be taken back for further consideration.

Dr. G. W. Ireland (Lothians) moved:

"That this meeting is satisfied that the British Medical Association, as at present constituted, is competent to undertake any necessary negotiations on behalf of the profession, and that the proposal to establish a British Medical Guild be abandoned."

He said that no one could read the carefully prepared memorandum put forward by the Council without appreciating that much detailed work and thought had been put into it. But there was a certain unsoundness in its arguments, and one was left with the impression that the Council were not very sure of themselves and had an instinctive dislike of the whole business. The trustees of the Guild would be the Council. It was a somewhat nebulous conception. The Council had seized upon the one road which seemed to be open, and without knowing where it would lead they were asking the rest of them to march along it. The reasons that had been given for the new organization were extremely poor and the thing itself was poorer still. In contrast they had the B.M.A., which had stood the test of time and had gone from strength to strength. It stood as one of the greatest democratic institutions in this country. It existed for the honour and interests of the medical profession, honour having precedence.

There were two things the Association could not do: it could not coerce and it could not finance its members when in difficulty. But he believed that the absence of those powers made the Association richer and stronger. The Council could continue to carry out all the necessary negotiations. He asked the meeting to maintain the prestige of the Council and in doing so to uphold the honour and dignity of the profession.

Dr. D. S. Robertson (Edinburgh) said that the Council's proposals had been rejected by his Division by a substantial majority. To a few of them the objection was that the Guild was not a trade union, but to the great majority the overriding cause for opposition was the belief that the proposed Guild savoured too much of a trade union, that it was as near an approach to a trade union as the Council could devise without incurring legal difficulties, and the concept of a medical trade union was still anathema to a great number of doctors. He would be greatly surprised if some sharp mind on the other side was not able to pick holes in this thin veneer of legality which was spread over the Guild.

Dr. Swainston (South Shields) was in complete agreement with the Lothians in its dislike of this proposed organization, but it did not approve the words "as at present constituted" in the Lothians amendment.

Dr. J. A. Pridham (Council) said that what they were doing was to extend over the whole of the profession the umbrella under which general practitioners had sheltered for twenty or thirty years. He hoped that the question of withholding service would never arise, but they all know that when they went into negotiations it was a great advantage to feel that there was weight behind them.

Mr. Eric Steeler (Marylebone) said it was a time for plain speaking. Up to January, 1948, the B.M.A. had been in the unique position of having a moral leadership unquestioned in the profession, as was shown by the last-but-one plebiscite.

Now the Council were so unsure of their moral influence that they themselves suggested a parallel body to do their fighting for them. The rot set in when the Chairman of Council made his *volte-face* between a certain Saturday evening and the following Wednesday mid-day. How could the individual member be sure of the Council when the Council was obviously unsure of itself? This feeling of lack of confidence was shown in the results of the last plebiscite and also in the setting up of two autonomous organizations—the General Medical Services Committee and the Central Consultants and Specialists Committee—and now by the proposal to set up a kind of Siamese twin with the B.M.A. itself. In so far as this proposed Guild had any meaning it was merely a legal subterfuge designed hopefully to cover illegal action. The essential step was to restore moral leadership, and the Representative Body should consider what was necessary to have that leadership concentrated in the Council. The Council was the servant of the Representative Body. This proposed Guild was built on the fantasy of wish-fulfilment and it was to be the Council's alibi.

Dr. J. G. Thwaites (Council) said that the essence of the Lothians amendment was that the Association was competent to carry out negotiations. But the Council had found that there were definitely weaknesses in its constitution. The intention of the Guild as proposed was to provide that strength to the Association which the Association lacked at the moment in its constitution. It was not a separate body, it was another arm of the Association.

Lord Horder's Criticisms

Lord Horder (Marylebone) said they in Marylebone had put forward a similar amendment, but would not press it if the mover of the Lothians amendment was willing to substitute the words "[the Association] should be competent" for "as at present constituted is competent." The Marylebone amendment was positive, and not negative like the Lothians amendment. In January of last year the Association was given a mandate by the whole profession to advise against service under the Act. That mandate enabled the Association to exercise very considerable moral force, such force as would have compelled the Minister to yield some of the excessive power which he had concentrated in himself.

If it was necessary to effect some reconstruction of the Association so as to prevent a repetition of the "sacrifice," then let such reconstruction be effected. But the setting up of a parallel organization did not do this. It added no extra power of a recognizable kind to the power which the Association already held. It left the construction of the Association unchanged. He found it difficult to understand what this new organization could do or indeed what it was. It seemed to have no local habitation, though it had a name. Like Melchizedek, it had no father and no mother. It was to have a board of trustees and to be able to collect money. But so had and did the ill-fated Independence Fund. They were asked to give the Guild a status with legal sanction such as the Association itself might not enjoy. But who operated the self-starter of this organization? Who determined its policy? The answer was the Council of the Association, and so they were back to the point from which they had started. He could not see that the "big stick" was any more than a pole carrying a turnip with the light inside. Who carried the pole? The Chairman of Council. When the pole was dropped and the light failed and the holder of the pole was exposed, was the charge, if there should be a charge, to be made against the turnip? The whole thing was as silly as the ostrich with its head in the sand. Was the Representative Body giving its dictates to the Council, and was the Council performing its function of implementing the dictates of the Representative Body? He saw a danger here. On the previous day the Representative Body had had no option but to approve a Report of the General Medical Services Committee, because that Report had already been approved by the Conference of Local Medical Committees and had been sent to the Minister, so that all the Representative Meeting could do was to rubber-stamp what had been already decided. He admired the very unusual capacity displayed by Dr. Wand in his office as chairman of an autonomous committee, but if they lost sight of the function of the Representative Body, which was to control policy, and of the function of the Council, which was to carry

out the dictates of the Representative Body, then they were diffusing and weakening the power of the Association. The setting up of this Guild was an evasion of their responsibility. Let the Association speak clearly, with its natural and not with a ventriloquial voice.

Dr. A. J. Macleod (Outer Islands) supported the Lothians amendment. He also asked that they should drop this whole idea of fighting. They were not fighting, but negotiating.

Dr. J. C. Arthur (Gateshead) said that in negotiations with any Government, unless there was some backing of force, they got nowhere. Were they to abandon the only methods which had been effective in the past? He urged that the Lothians amendment be turned down.

Dr. J. Riddell (Edinburgh) said this proposal was to be deprecated. It had been agreed that there should be set up Whitley Council machinery for the profession, which involved, in the event of dispute between employer and employee, a recourse to independent arbitration. If they had a Medical Guild it would mean that they had a bludgeon should the arbitration go against them, and such a thing could do nothing but lower their prestige throughout the country.

The Chairman of Council's Reply

Dr. Dain said that a number of excellent speeches had been made, but many of them had not been directed to the amendment at all. If the Representative Body was prepared to say that the B.M.A. as at present constituted was competent to undertake any necessary negotiations it was directly contrary to the opinion which the same body had expressed at Cambridge. The Council had acted here, as on all occasions, as the servant of the Representative Meeting. The Representative Body gave instructions that this problem should be dealt with and the Council had brought before them its considered conclusions. If it were true that the Whitley Council covered all possibility of disagreement with the Government there would be no need for this new body. But the Whitley Council would cover only certain aspects of their contract and there would be a field outside Whitley Council procedure which must be covered by themselves.

Lord Horder had made an engaging speech, but he had not offered any practical proposals for dealing with the problem that the Representatives themselves had set the Council. He reminded them that they had to deal with two defects in the constitution—namely, that the Association could not act as if it was a trade union, and that it could not use its funds to support its members who suffered in consequence of its policy. They were advised that the Guild would not be liable to an injunction, although it would be liable to an action for damages if it did anything which was damaging to an individual, whereas a trade union in furtherance of a trade dispute would not be so liable.

Dr. Barbara Woodhouse (Harrow) said that a year ago they had not felt that the B.M.A. was competent to deal with the problem before them. She asked that the amendment be rejected, having in mind that there were on the agenda further motions which would enable this matter to go back to the Council for yet more consideration.

Dr. H. H. D. Sutherland (Council) supported the Lothians amendment in opposition to the view taken by many members of Council. What they had here was another organization in embryo which was really part and parcel of the B.M.A. It was not, as it stood at present, really independent, and it could be shot at legally. This would not give them the protection that they needed. Dr. Thwaites had pleaded for a strong right arm for the B.M.A., but a subsidiary company, which in effect this was, could be shot at legally just as much as the parent company.

Dr. O. C. Carter (Council) asked whether the Representative Body knew its own mind? If it was satisfied with the medico-political state of the profession then the Lothians amendment should be carried. Representatives had to make up their minds whether they wanted the Association to be efficient to fight a battle if it occurred. If they were satisfied that there was no battle ahead, then let them carry the amendment.

Dr. E. C. Warner (Marylebone) supported the amendment, saying that the formation of the Guild did not give any effective bargaining force for use against the Minister.

Mr. A. Staveley Gough opposed the amendment.

Dr. W. E. Dornan (Sheffield) said that the Guild was purely the establishment of a "pocket" into which the Association could put its hand. He agreed that the mere establishment of the Guild would not be sufficient and that the response of the profession with subscriptions over a long period would be a necessary corollary. But he thought the recommendation of Council should be supported.

Dr. R. W. Cockshut (Hendon) had been convinced by the debate that to move in the direction of this Medical Guild would be a mistake. Mr. Steeler and Lord Horder had convinced him. The tone of the Marylebone speeches suggested the right road for them to follow, not the easiest road, but the one which in the future they would be proud to have taken.

Dr. G. W. Ireland, in reply, said that Dr. Dain seemed to indicate that the Council had been given a mandate to produce something. But the Cambridge resolution was "to explore the possibility." On the one side, in the Association itself, they had something that was proved and positive; on the other side, in the proposed Guild, something that was nebulous and negative.

In reply to a question he said he was quite prepared to drop the words "as at present constituted" from his amendment. They were not significant from the point of view of his Division. On a show of hands the meeting gave permission for this, 169 to 132.

The Lothians amendment was therefore put to the meeting in the following form:

"That this meeting is satisfied that the British Medical Association is competent to take any necessary negotiations on behalf of the profession, and that the proposal to establish a British Medical Guild be abandoned."

On a show of hands the amendment was lost by 107 to 217.

Reference Back Proposed

Dr. J. A. Gorsky (Westminster and Holborn) moved:

"That this meeting, while agreeing that a parallel body is necessary for the protection of doctors, considers that until the whole legal position is clarified, the question of the constitution of the Association should be referred back to the Council for further consideration."

There was a genuine difference of legal opinion on this subject and therefore he felt the matter should be referred back to Council. There were grave doubts as to the validity of this Guild, which was not an independent body. He was of opinion that another parallel body should be constituted in order to carry out what the Association could not possibly do.

Dr. R. P. Liston (Tunbridge Wells) supported the reference back. He agreed that a new body should be established for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, but in view of the fundamental conflict of legal opinion on the constitutional position further consideration should be given to the matter.

Dr. S. F. L. Dahne (Reading) said the Council's motion was a shadow of what they really wanted. If more detailed consideration were given to the national, legal, and medico-political aspects it might be possible to build up the unity which they all needed to carry on the battle for the freedom of medicine. He asked that the matter be referred back for further consideration.

Dr. Frank Gray (Council) asked why they were present at that meeting to-day instead of waiting until Harrogate. It was because they felt at Cambridge last year that this question was vital and urgent. No doubt the members of this body slept well last night with roseate dreams of £16,000,000, but they had not got it yet. Supposing the Ministry did not agree to hand over that sum, what preparations had they for meeting the situation? They were faced with a dispute a year ago, and they had to sit down when they should have been doing something more important and hurriedly develop a fighting organization. When they should have been ready for battle they had to go back and build up their armaments. The Council's proposal was really a modest one to set up a piece of machinery which would do things which the Association could not do and be ready to function now in any dispute which might arise.

Dr. D. E. Yarrow (Tunbridge Wells) said that moral force could only be obtained by attracting substantial support from

the whole of the profession. This support would not be forthcoming for a British Medical Guild. This matter should be referred back to Council.

Dr. K. Watson (Rugby) said the matter should be referred back. It was said that the decision was urgent. But no one had yet suggested that the Guild would have any more power within a measurable distance of time than the B.M.A. already enjoyed. The only money on which their hands could readily be laid was the money in the National Insurance Defence Fund.

Dr. I. D. Grant (Glasgow) said that opinion in West Scotland was different from what it was in East Scotland. In Glasgow they were in full sympathy with the view that some such body should be formed—that some such organization should be grafted on to the B.M.A. At the same time they should not be in too great a hurry. It was necessary that this new body should have the full confidence of the profession, and for this purpose more education must go on at the periphery. If this was to be an umbrella for the whole profession, obviously the whole profession must be taught to shelter under it.

Mr. G. D. Falconer (Wallasey) and Dr. J. C. Robertson (Norwich) supported the motion to refer back.

The Chairman of Council said that in three months' time they would be in no better position to settle the legal argument than they were to-day. The machinery which had been in operation for the National Insurance Defence Trust had met the similar problem which had to be solved in the days of national health insurance. When such a Guild had been established and set going it could no doubt, on any alteration of the law, without much difficulty be converted into a trade union if and when the Representative Body thought that was a proper thing to do. But they would be no better off by postponement, and the sooner they started the better.

Dr. Gorsky, replying, said that all the limitations which were imposed upon the constitution of the Association would be reimposed upon the trustees if this proposal as it stood were put in practice. There was great doubt about the legality of the trust deed, and on that point alone he asked for the reference back.

The Solicitor (Mr. Taylor, of Messrs. Hempsons), in reply to a question, said that when the trust deed appended to the present report was prepared it was approved by counsel, and the trust deed of the Independence Fund, which was very similar, was approved by another counsel, and in the opinion of them both, as well as in his own opinion, actions by the trustees would not involve the Association, and the funds of the trustees were quite different from the funds of the Association.

Asked whether it would be possible for the B.M.A. to give away some of its money to the Fund, the Solicitor replied, No, it would not be lawful. Asked further what money would be available to defend the trustees in court should action be brought against them, the Solicitor said that the money in the hands of the trustees could be used.

The motion to refer the matter back was lost.

Support for a Trade Union

Mr. H. B. Bullen (Hastings) moved :

"That in view of the desirability of medical practitioners' having the full protection given by a trade union under the Trade Disputes Act, 1906, the formation of the Guild suggested in the Council's recommendation is quite inadequate to meet the situation, and the Council should make every endeavour to make a trade union available to the profession if this is legally possible."

He considered that the Guild would not be sufficiently strong to wage a fight against a determined Minister.

Dr. Pearson (Birkenhead) considered that if a trade union were started allied to the B.M.A. the profession would be given a far greater sense of security. To suggest that members of the medical profession were not "workmen" was a quibble. If his contract with the local executive council did not make him an employee he did not know what did.

The Chairman of Council agreed that the Guild might not be as effective as a full trade union would be if a trade union were possible and legal, but at the moment the Guild was the most effective method that could be offered to the profession. He was astonished at the last remark of the last

speaker. They had carefully arranged a service for general practitioners in such a form that the practitioner was employed by his patients; his contract was for each individual patient; and yet the speaker had assumed that he was the paid servant of the local executive council.

The Hastings amendment was defeated by a heavy majority.

Other Methods of Organization

Dr. A. Brown (Cambridge and Huntingdon) was of opinion that existing bodies should be used as the parallel organization, the General Medical Services Committee acting for general practitioners, and analogous councils or committees for other groups, with a central committee to act as the co-ordinating body. He moved an amendment to that effect.

Dr. Ff. Roberts (Cambridge) supported the amendment from the standpoint of consultants and specialists. Concerted action was difficult enough for the general practitioner, but almost impossible for the specialist. The organization proposed by Cambridge did seem to offer some advantage. Dr. K. S. Maurice-Smith (Isle of Ely) thought that what Cambridge was suggesting was a little bit better framed and more "visible" than a nebulous Guild.

Dr. H. H. D. Sutherland (Council) considered this amendment to be one of the star points of the meeting. In these days amalgamations of various kinds in the higher spheres of politics seemed to be important means of getting things done, and on their own level in what was now proposed they had, as it seemed to him, a grand opportunity for an affiliation arrangement with the Medical Practitioners Union and for an act of fraternization with the Fellowship for Freedom in Medicine. These bodies might have a part in the central committee.

Dr. C. W. Walker (Cambridge) said that their whole idea was one step at a time. Was it really suggested that, if there was a "row" over the 16½ million, the money in the National Insurance Defence Fund could not be used in the service of practitioners? What did they subscribe it for? The set-up of a Guild was not going to help at all.

The Chairman of Council said that Cambridge and Huntingdon had lost sight of the important fact that the committees of the Association could not be used for the purposes of the Guild. There was no intention to forgo the use of the National Insurance Defence Fund, but that could deal only with one part of the profession.

The Cambridge and Huntingdon amendment was lost.

Membership of the Guild

Dr. J. C. Arthur (Gateshead) moved that eligibility for membership of the British Medical Guild should be open to any member of the medical profession who agreed to the appropriate terms and conditions. It was objected that if they had a Guild of members the members would tend to outrun the Association, and thus a separate body, not merely in title and organization but in spirit and aim, would be created. But it was specified in his amendment that members must agree to the appropriate terms and conditions, and they would have their solid Council membership at the top of the organization. A Guild with membership would be a much more effective machine.

Dr. Frank Gray (Council) said this question of membership of the Guild was founded on a misapprehension. The proposal was to set up a parallel organization, with trustees who would be the same persons as the members of the Council. It might therefore be said that there were adequate means of ensuring that the trustees would be acquainted with the Council's views. It was true that the constitution of the Association could not be changed, but by setting up this Guild they would get perhaps as near to doing it as they might desire. The important thing was to have a machine which would work, and the question of membership was therefore completely irrelevant.

Dr. H. H. D. Sutherland (Council) said that surely this new body must have membership—hands to work, and feet to carry it—at the periphery.

The Chairman of Council said that the plan put forward maintained the Representative Meeting as the policy-making body, and it furnished a method for implementing the policy without having to use the machinery of the Association.

Dr. Arthur had said that people would not take an interest in the Guild if they were not members. The experience of the N.I.D.T. did not support that. Members of the profession subscribed to it, although they were not members.

The Gateshead amendment was heavily lost.

Dr. J. C. McMaster (West Somerset) moved that any agreement to the formation of the Guild should be conditional upon the money paid through the former insurance committees to the National Insurance Defence Fund being transferred to the Guild and the allocation to it of any future contributions to the Defence Fund.

Dr. S. Wand (chairman of the General Medical Services Committee) said that it would be improper to pass this amendment. It was not the business of that meeting to tell the trustees of the Defence Fund what they should do with the money which had been subscribed. He could assure them that the trustees would see always that the moneys subscribed for helping doctors were used in that way.

The amendment was withdrawn.

Dr. H. W. Pooler (Chesterfield) said that the idea of a trade union was anathema to many members in his Division, and a body by any other name would smell no sweeter. But in the end the Division had authorized him to vote for the Guild if its formation was agreed to by a two-thirds majority on a ballot of the profession.

The Chairman of Council said that it was much better that a decision on this point should be made by the Representative Body, which had been fully informed on the subject.

The proposal for a ballot of the profession was lost.

On a proposal by Winchester that the new organization should be entitled "The Guild of the Medical Profession" the meeting passed to the next business.

This exhausted the amendments, and the original proposal of the Chairman of Council, that a new organization be established for the better protection of the interests of the medical profession in disputes with public authorities and other bodies in the form of an independent board of trustees with power to organize and finance collective action, and that its name be the British Medical Guild, was then put to the meeting and carried by more than the necessary two-thirds majority.

Other Motions

Dr. R. H. D. Lavery (Coventry) moved to ask the Council to approach the appropriate bodies representing the dental and pharmaceutical professions with the suggestion that they be associated with the Guild.

The Chairman of Council said that the Council might look at this, but at first sight it did not look as if it would succeed. The motion was lost.

Dr. J. C. Arthur urged the great importance of mobilizing immediately available funds for the starting of the Guild and establishing a skeleton organization at the periphery.

The Chairman of Council said that Dr. Arthur as a member of the Council would be able to take his part in furthering this. Matters were in hand, and they had only awaited the approval of that meeting to get along with things as rapidly as possible.

Several motions at this point were referred to Council. These included proposals for the financial target for the first year, the establishment of a minimum subscription, the deduction of contributions at source, and a suggestion by Burnley that in the event of an emergency not arising within ten years the accumulated funds should be applied to some form of endowment insurance for the benefit of subscribers. Worcester and Bromsgrove moved that provision should be made for extending the deed beyond the period stated (the lifetime of the longest liver of the issue now living of Edward VII and twenty-one years thereafter), but after the solicitor had explained the legal form for documents of this kind the motion was withdrawn.

Dr. J. A. Gorsky (Westminster and Holborn) moved "That this meeting calls upon the Minister of Health to include in the amending Bill a clause which shall state that registered medical practitioners are 'workmen' for the purposes of the Trade Disputes Act." The word "workman" must not be regarded in a derogatory sense. It was a legal word used in the Act in order to give workmen protection. This was a means by which in effect members of the medical profession could at a future date enjoy the privileges and protection of

the Act. A committee was now sitting on the amending Bill, and if the meeting wished the motion could be referred to that committee for further consideration.

Mr. C. F. Mayne (Plymouth) said that in this connexion there seemed to be a difference in status between different branches of the profession. Did a consultant or specialist who was paid by the hospital board, and who had part of his contributions to the National Insurance Fund deducted, not become a "workman" according to this definition, as opposed to the general practitioner who was self-employed?

The Chairman of Council said it would be unwise for that body, representing as it did the enormous majority of the profession, to ask the Minister to make them into "workmen" in order that they might fight him more successfully in time to come. It would be an impolitic move.

Dr. Gorsky urged that this should not be rejected out of hand. He could not see any reason why the Minister, who was favourable to trade unionism, should reject a request by the doctors to accept protection under the Trade Disputes Act. It would be an act of faith on his part, and he could introduce it into the amending Bill. It should be considered by the Amending Bill Committee. It would solve all those legal difficulties which they had had before them that day.

It was agreed to refer the motion to the Council.

The business of the meeting concluded with a vote of thanks to the chairman.

HEARD AT HEADQUARTERS

Association War Memorial

The memorial at B.M.A. House to members of the Association who fell in the recent war will probably take the form of a fountain to be erected in the Court of Honour. That is the suggestion of the committee which has been considering the subject under the chairmanship of the Chairman of Council. It is proposed that there should be a limited competition among three sculptors to be chosen by assessors for the design of the memorial. The fountain will bear a dedicatory inscription prepared by the Association, and the names of those it commemorates, like the names of those who fell in the earlier war, will be inscribed in a Book of Honour. The entrance gates to the court are a memorial to the 574 members of the Association who fell in the first world war. They were designed by Sir Edwin Lutyens and made by the Birmingham Guild. They are surmounted by a bronze shield with the words on one side "Memory and Praise" and on the other "Faithful Hath Been Thy Warfare." The new memorial is expected to cost £10,000, and an appeal will be made to members to bear the cost.

Gaiety Revived

The bygone gaiety of Tavistock Square will be revived on Thursday, May 26, when the Metropolitan Counties Branch is arranging a ball at B.M.A. House in aid of medical charities. For many years now little has been heard at Headquarters but the sound of typewriters and the murmur of conferences and committee meetings. Some may remember a festive occasion nearly twenty-five years ago when, on the evening of the day after the royal opening of the new house, the Metropolitan Counties Branch organized a similar occasion. The Great Hall is unique among the halls of London, with its high vault supported by rows of Corinthian columns of brilliant peacock blue, and makes a wonderful setting for revelry by night. In the Court of Honour outside, the proposed memorial fountain will not be in place, but the Minister of Fuel and Power has lifted his ban on display lighting in time to permit flood-lighting or other illumination. Perhaps some famous ghosts will be present. Just ninety-two years ago on this very spot Charles Dickens was the leading actor in a series of theatrical performances, when the four hundred guests included some of the highest in the land.

A Permit to be Ill

A long foolscap form came our way recently which had been elaborated by a group of Civil Servants. It looked like the

report of an examination for life assurance. It was headed "Application for a Permit to be Ill," and it began in the orthodox way: "I hereby make application for a permit to be ill." Then follows a long series of questions, as, for example: "I have broken my (a) arm, (b) leg, (c) neck, (d) engagement." Again: "During the last 12 hours I have been sick times. I expect to be sick again in hours." "I am afraid I shall (a) die, (b) live, (c) not die, (d) not live (strike out inappropriate words)." "The name of my (a) doctor, (b) veterinary surgeon is....." It is good to find Civil Servants with a sense of humour.

Transcontinental

Divisional meetings in this country seem brief and slight affairs compared with the way they arrange them in the Canadian Medical Association. A schedule we have received shows that the divisional meetings for Manitoba, at Winnipeg, for Alberta, at Edmonton, and for British Columbia, at Victoria, will each last four days, all in the latter part of September, and the divisional meetings for Nova Scotia and for New Brunswick, held a little earlier in the month, will each last three days. The entire programme, covering seven provinces from the Atlantic to the Pacific, involves twenty-one days of meetings. A warm invitation has been extended to the President of the B.M.A., Sir Lionel Whitby, to pay a visit.

Questions Answered

Unnecessary Calls

Q.—Recently at 2.15 a.m. I was sent for by a registered patient for heart trouble. On arrival I found her very vocal, but examination showed no sign of cardiac distress. Neighbours were in, and tea and biscuits were much in evidence. I take it we are compelled to attend these calls, but in a case like this have we any remedy or any protection?

A.—A practitioner is required to render to his patients all proper and necessary treatment and is required to visit and treat a patient whose condition so requires at any place where under the terms of his application for inclusion in the medical list he is under an obligation to visit such patient. Where a patient continues to call the doctor to the house unnecessarily it is open to the practitioner to ask to have the patient's name removed from his public list. In isolated areas, however, this step may prove difficult, and an amendment to the Act is being sought so that a practitioner may lodge a formal complaint against the patient under similar arrangements as existed under the National Health Insurance.

Compensation

Q.—I and my two partners have been practising since before July 5 as anaesthetists. We are all three part-time employees under the State, but I am told no compensation is payable for the loss of the saleable value of the practice unless we join the scheme as G.P.s. Is this the case, and, if so, are any negotiations dealing with specialist partnerships in train at present?

A.—General practitioners entering the National Health Service are deprived by the Act from selling the goodwill of their practices subsequently, and it is for the loss of this right that compensation is payable. No such restriction on buying and selling applies in the case of specialist practices, and the Ministry has stated it cannot accept liability for any loss in the saleable value of a specialist's practice arising from the introduction of the public service.

A practitioner engaged partly in general practice and partly in a specialty who entered the Service on the appointed day as a general practitioner would be unable subsequently to sell any part of his practice and would base his claim for compensation on the value of the practice as a whole. Normally a general practitioner entering the Service after the appointed day is not entitled to compensation, but it is proposed in the amending Bill to make provision for compensation for partners entering the Service after the appointed day but before a date yet to be specified.

Correspondence

Relations with the Local Press

SIR.—It may interest other Divisions to read of a meeting which this Division's officers arranged last week with representatives of the local Press, and it was so successful that news of it may stimulate others to arrange similar meetings in their Divisions.

It may be stated that the relations in our locality between the doctors and the Press have always been happy; nevertheless, it has been our opinion for some time past that only good results could follow a closer liaison and lead to a better understanding of the problems confronting both professions. As this was our first official approach, though the meeting was to be quite informal, we felt that our object would be appreciably facilitated by the presence of Mr. John Pringle, the Association's P.R.O., and it was. He emphasized in his talk the supreme importance of developing mutual confidence between the professions, for without it no closer contact would be possible; it would prevent "stunting" and discountenance lurid reports.

It quickly became obvious that the Division's suggestions to help the Press, through our secretary, to obtain up-to-date and factual knowledge on medical matters, whether of scientific or medico-political interest, were warmly welcomed. It was recognized by the Press that this represented a genuine desire of the Division to be co-operative. It was surprising to discover how deeply concerned were the local Press at their exclusion from the Group Hospital Committee, and they were anxious to know how far the influence of the B.M.A. might be brought to bear to remedy a state of affairs which they considered to be potentially dangerous. There were many other matters of mutual interest which were discussed but which do not require to be mentioned in this letter.

It is logical to suggest that the efforts which the P.R.O. is making at Headquarters to improve relations with the national Press should be backed up locally by Divisions with their own Press.—I am, etc.,

R. P. LISTON,
Tunbridge Wells Division

Fair Annual Income

SIR.—It is probable that the capitation fee will be increased in the very early future. Financial strain and the burden of increased work under the Health Service will strongly tempt most of us to accept the new figure provided the majority of the profession consider it reasonable. Before falling again easy prey to the cunning machinations of our overseers, let us not forget that, having once accepted the new figure, it is certain, with the rising tide of newly qualified doctors, that the present N.H.S. lists will be severely pruned to possibly 2,000 or 2,500 units. Concurrently, our annual income will be cut back in proportion and obviously will not then be anything like adequate.

The profession must then once again demand from the Ministry a further increase of capitation fee to compensate for loss of patients. The Minister will reply that he has already agreed, and the profession has accepted, one increase, and that to consider a second would not be practicable in the public interest. In short, we shall have "had it."

Assuming we accept an agreed increase of the present capitation fee, and that at some date subsequently and not too far distant Mr. Bevan demands this inevitable cut in lists, what will our *minimum* annual income be then? Will such income be fair in comparison with other professions not on 24-hour call throughout the year; and will the Ministry turn a deaf ear to a demand for an increase on a second occasion?

Before agreeing and accepting an increased capitation fee retrospective to July 5, 1948, let us imagine that on Mr. Bevan's instructions our list has already been cut to 2,000 or 2,500 units, and on *this* figure—and not on our present number—let us assess with the guidance of experts the annual value of our responsibilities to the public. With a list of possibly 2,000 units only, what is a fair annual income for a doctor?—I am, etc.,

Birmingham

G. A. POWELL-TUCK.

Dispensing Practices

SIR,—May I through your correspondence columns relate my own experiences in connexion with dispensing for N.H.S. patients, in the belief that most rural practitioners will find it a considerable financial advantage to adopt a similar system?

During the first quarter of the N.H.S. I accepted the drug capitation fee for patients on my dispensing list, and found that the sum I received barely paid for the drugs I had purchased during the quarter. The increment left over after the accounts were paid would certainly not have paid a dispenser. I decided to try payment by the alternative method of submitting prescription forms for every item dispensed and having these priced at the Pricing Bureau in much the same way as the pharmacist does. To my surprise and gratification I found the sum I was paid was rather more than double the amount I would have had from the capitation fee.

The way I have chosen does involve extra work, as I have to write out prescription forms when the day's work is done, copying from a rough dispensing book, but doctors whose practice is large enough to employ a dispenser should have no real extra work if they write out the prescriptions when they see the patient and send them to the dispenser for recording and to make up the medicine required.

My own experience and that of the pharmacists to whom I have spoken shows that the average value of a prescribed item is roughly 2s. The capitation fee is 6s. 2d. per annum. I assume that the Minister takes it that each person will require three items of medicine per annum on an average. My own figures suggest that the average will be eight or nine items per patient per annum, which is presumably the reason why I appeared underpaid on the capitation-fee method.

I consider that the capitation fee for dispensing is essentially immoral, anyway, as it encourages doctors to prescribe the cheapest remedy likely to keep the patient contented rather than that which will do him most good. Further, it penalizes the rural patient, because the town doctor can prescribe anything in reason, while the rural doctor has to watch his drug bills. Even if the Minister conceded a drug capitation fee double the amount at present paid I should hesitate to change from the present system; it would certainly require to be doubled before it would tempt me.—I am, etc.,

Allstree, Derby.

J. A. WARD.

Position of Registrars

SIR,—May I beg the courtesy of your columns to ask publicly exactly what the B.M.A. are doing on behalf of the chief assistant and registrar class in their negotiations concerning appointments and remuneration under the N.H.S. Act? Much appears to be written and said concerning the G.P. and consultant but little about this class, composed as it is mainly of ex-Servicemen. Grateful as we are for the war service grants which have enabled many of us to specialize who might not otherwise have done so, it is now nine months since the Act came into force, and despite the acquisition of higher diplomas and promises of new appointments we are still "supernumeraries." Further, because of superannuation contributions and deductions for N.H.I., our "grants" are getting less and the prospect of permanent and adequately paid posts more remote unless urgent action is taken to rectify matters. May I therefore urge upon the B.M.A. the following line of action:

- (1) To settle with the Government the question of remuneration and posts for registrars before those of consultants, few of whom are suffering hardship consequent upon the delay in implementing the Act.
- (2) To stop any further grants to intending specialists until those at present receiving them have been absorbed into permanent appointments, thus preventing the supply exceeding the demand when new establishments are finally decided upon.
- (3) To ensure that all posts advertised of a newly established nature and requiring a higher qualification are offered first to those who obtained their diplomas prior to July 5, 1948, thus ensuring that no registrar is penalized, through no fault of his own, for the lack of proper implementation of the Act on the appointed day.
- (4) To insist upon retrospective remuneration to July 5, 1948, according to experience and qualifications on that day (when we were led to expect the Service would embrace us).
- (5) To ensure that war service in the armed Services counts in some measure towards seniority in the new appointments (since it would appear obvious that it was easier to obtain higher diplomas at an earlier date after qualification outside the Forces than when in them).

Although some of my colleagues may not agree in entirety with all the points enumerated above, I feel nevertheless that they will agree whole-heartedly in urging the B.M.A. to "get on with it" and do something for the registrar class as well as for the G.P.s and consultants.—I am, etc.,

Manchester.

I. LANGDALE GREGORY.

* The Secretary of the B.M.A. states: Representations have been made to the Ministry of Health on two occasions that for registrars and those of similar status the new rates of remuneration should be brought into operation forthwith with retrospective application to July 5, 1948. So far the Ministry has taken no action. It has been pressed to take action in England and Wales without further delay.

Abolition of Partnerships

SIR,—May I reply to "Assistant" (*Supplement*, March 12, p. 140)? I can see both sides of the issue, because I entered practice when I left the Navy in 1945, became a partner in 1946, and have had an assistant since 1947. I agree that most assistants are far more competent than their principals. "Assistant" need not rub that in.

I am sure that the B.M.A. has adopted the right approach to the problem of too many assistants trying to enter non-existent possible partnerships. We, the principals, mostly desire a partner in place of an assistant (anyway, I do) because the patients prefer continuity instead of change of doctors. I have had four assistants in over two years, counting locums. The principal at present just cannot afford to take on a partner at £1,200 to £2,000 until the capitation rate is raised. The increased capitation rate will allow of the entry of new partners to overworked practices.

I should like to say a few kind words to "Assistant" about abolition of partnerships. It is somewhat easier for the incoming, unbefriended, possibly inexperienced, and wholly without-patients young doctor if he is working with the man who is overburdened and eager to introduce him to the nucleus of what will become his own individual practice. Personally I want to limit my own list to 2,500 or 3,000 and pass on a large block of excess patients to my new partner. I believe 3,000 is the maximum list that one can look after properly. I am sure "Assistant" does not realize what a long time it takes to work up a practice simply by putting up a plate, even if there is a local redundancy of patients sculling around.—I am, etc.,

ONE PRINCIPAL

The Cost of the N.H.S.

SIR,—It is well that Dr. Ffrangcon Roberts's provocative essay on the cost of the N.H.S. (*Journal*, Feb. 19, p. 293) has not gone unchallenged. Recognizing that the achievements of sociologists and of social medicine are a danger to his concept of civilization, Dr. Roberts easily disposes of them at the outset: "I can only reaffirm categorically that with the possible exception of tuberculosis none of the major diseases and few of the minor ailments are in any degree attributable to this cause [poverty]." One is reminded of Canute.

Upon this frail but bold assumption Dr. Roberts proceeds to construct his austerity budget for the N.H.S. In passing, it is remarkable that he does not appear to have realized the full magnitude of his opportunities once the bogey of poverty is laid. For by dispensing with all those costly social services provided at the expense of the taxpayer (mistakenly, it seems) to keep the people alive and in good working health, what an enormous contribution could be made to "national prosperity."

The "remedies" Dr. Roberts proposes, the most unpleasant of which he does not divulge, referring to them darkly as "measures which, to put it mildly, will be anything but pleasant," seem to be as follows. Since all psychological disorders (or "imagined ill-health") are, he is convinced, due entirely to faults in the individual, having nothing to do with his environment, "determinist" folkies and extravagances in attempting to ameliorate the material and social conditions of the psychologically ill should cease forthwith. Presumably,

if such people seek their doctor's advice they should be told to pull themselves together. Or should we threaten them with Dr. Roberts's "anything but pleasant" measures?

Next, we should cease wasting money on all those who cannot be restored as productive workers. This sentence would be passed in the first place on those suffering from diseases which are permanently incapacitating, but would doubtless be extended to other categories of "undesirables." For Dr. Roberts civilization has gone far enough already, if not indeed too far; it now threatens "national prosperity" because of its profligate coddling of these uneconomic people. Have we so soon forgotten Hitler's extermination camps for the unfit?

Finally, Dr. Roberts has decided that "we are certainly moving towards a point" at which "national prosperity is threatened" by the further advance of medicine, which now only increasingly "promotes the survival of the unfit." We should therefore abandon our dangerous attempts to advance medical progress. Not content with abandoning the cause of medicine ourselves, we should teach our students that its advance constitutes the gravest threat to national prosperity, and that the people's desire for good health is in conflict with their country's well-being.

Such "solutions" as these would undoubtedly add to the list of "nations which have been decimated by disease." Such nations have often recovered, Dr. Roberts tells us, but changed in social structure. It hardly seems likely that this was the aim he had in mind.—I am, etc.,

Newbury, Berks.

J. ATKINS.

Health Centres

SIR,—Judging from your report of the Royal Society of Medicine discussion on "Health Centres" (March 19, p. 494) I did not make myself clear in my contribution. May I try to do so now? Referring to the West Ham scheme (for provision of a trial health centre in an adapted building), it is not "hoped to start in three months from now." I wish it was. If local hope, enthusiasm, and initiative counted for anything West Ham's centre would have been in operation before now.

My reference to "three months" was to the time that would be required to complete the centre after work had started. When, if ever, will this be? Ministerial policy was originally in favour of the early provision of some experimental health centres by adaptation of existing buildings. It would now appear to have dithered to the other extreme of "Woodberry Down," and to regard the one as excluding the other. But, Sir, are they mutually exclusive? Even if we are, for political reasons, to be fobbed off with *one* castle in the bracing air of Woodberry Down in two or three years' time, would not the development of this prototype be greatly assisted by the development of West Ham and other proto-prototypes, ready in much less time and at a fraction of the cost? In these could be learnt the art of cementing persons into a team—much more important even than that of bonding bricks and mortar into a building.—I am, etc.,

London, E.16.

HARRY BOYDE.

Graduated Capitation Fee

SIR,—Dr. J. W. O. Holmes's letter (*Supplement*, March 26, p. 164) is very much to the point, and a tapering fee is grossly unfair. I have some recollection of a doctor writing to the *B.M.J.* stating that he combined medical practice with sheep farming in Wales, and that the capitation fee from sheep was greater than that from his patients. He also stated the sheep were less trouble.

I personally live in the best English county. I have a considerable number of appointments outside the National Health Service, and during the summer am able to go trout fishing three afternoons a week. Is it just that the practitioners who devote the whole of their time to the National Health Service in places like Manchester and Glasgow should subsidize me and my sheep-farming colleague? If such a system is brought into force there will be a tendency for doctors to move from the industrial areas, and the price of farms and the cost of trout fishing will rise.—I am, etc.,

Fareham, Hants.

Branch and Division Meetings to be Held

BOLTON DIVISION.—At Town Hall, Bolton, Wednesday, April 7.30 p.m. Combined meeting with Bolton Medical Society. B.M. Lecture by Mr. R. L. Newell: "Carcinoma of the Colon."

NORTH MIDDLESEX DIVISION.—At Prince of Wales's Hosp Tottenham, N., Tuesday, April 12, 9 p.m. Address by Dr. H. Ramsay: "Some Aspects of Miniature Mass Radiography," follo by films. Comments by Dr. Vernon Davies.

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hosp Wednesday, April 13, 8.15 p.m. Dr. W. S. C. Copeman: "Moc Views and Therapy of Rheumatic Diseases."

Meetings of Branches and Divisions

LINCOLN DIVISION

A general meeting of the Division, which all practitioners in are were invited to attend, was held on March 17, with Dr. A. Maiden in the chair. Twenty members were present.

The chairman opened a discussion on the Report of Council on constitution of the B.M.A. Dr. McClure put forward a resolut that "This Division views with alarm and strongly deprecates proposal to set up a board of trustees or similar body which have any powers of sanction or punishment over members of medical profession." Dr. Friskney seconded, saying that, though minority should fall in with the views of the majority, in a pro sional association there should be no coercion. Dr. Robertson supported the resolution; he thought that anything in the nature of trade union was undesirable. Dr. Buchanan felt that the ma should be deferred till after the Representative Meeting. Dr. Lillic opposed the resolution; he thought that the hand of the B.M. needed strengthening; its weakness was shown by the poor at dance at the meeting. The chairman was also against the motion; thought that the B.M.A. as at present constituted was too tied to take effective action. To clarify the matter he proposed: "This Division is in favour of a guild or similar body, but is in favour of restrictive practices being applied to any membe This proposal was seconded by Dr. Robertson and was carried 18 votes to 2.

The meeting next considered remuneration. Dr. Robertson thou that it was wrong for the B.M.A. to remain tied to Spens. thought that Spens could be implemented only in a salaried serv He was in favour of a fixed capitation rate which gave a be relationship to the amount of work done. Dr. O'Brien thought t to increase the capitation rate for the first 1,000 only was a mista Among other things, it would encourage everyone to take a parti Dr. Semple asked: "Do we want lists of 4,000 and an ea attack of coronary thrombosis, or lists of 2,000 and a high stand of medicine? Surely this latter was preferable." On the propo of Dr. Sharrard, seconded by Dr. Buchanan, it was agreed with dissent that this Division support the resolution of the Confere of Local Medical Committees.

Annual Report of Council: Correction

Under the heading "Organization" and the subheading "Plan Grouping for Direct Election of 37 Members of Council" in Annual Report of Council at p. 193 in the *Supplement* of April 2 error occurred in listing the Southern Branch. It should read follows:

Group	Area in terms of B.M.A. Branches or Divisions	Proposed	
		No. of seats	Member- ship
O	Southern Branch Dorset and West Hants Branch	1	1,394

BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 16 1949

IN PRAISE OF IDLENESS*

BY

Sir HENEAGE OGILVIE, K.B.E., M.Ch., F.R.C.S.

Surgeon to Guy's Hospital

The distinction of delivering the Beyer Memorial Lecture in Johannesburg is the culminating-point of a train of events that started when I went from Oxford to Guy's in 1910. Here I found myself among South African students, and later I numbered many South Africans among my colleagues, my pupils, and my friends. It was therefore only natural thirty years later, when the world decided to evict Mussolini from his Ethiopian empire and entrusted the task of throwing him out to a small force whose medical and specialist services were largely South African, that I should be appointed Consulting Surgeon. In that East Africa Force, whose advance from the Juba to Addis Ababa has never been approached in brilliance by any other campaign before or since in military history, I met for the first time many South Africans, soldiers and doctors, who are my firm friends to-day. After the fall of Addis Ababa I eagerly seized the occasion to visit the wounded in the base hospitals and specialist centres of the Union.

South Africans come to Guy's to learn medicine and to play Rugby football. They are not merely excellent players, they are also able to tell each other in Afrikaans where the ball is coming, and whether they intend to pass or run on. This ruse failed, however, when we met our great rivals St. Bartholomew's Hospital in 1910, for playing back in the Bart's fifteen was a young South African, Christian Beyers, the man we are honouring to-day.

The students of other hospitals sometimes accuse those of St. Bartholomew's of giving themselves airs. They say, "You can always tell a Bart's man, but you cannot tell him much." Yet they all respect the oldest hospital in England, the medical school that trained Pott and Abernethy, Paget, Butlin, and Bowlby. No one could accuse young Beyers of superiority; he was the most sincere and the most modest of men. No one could call him a bookworm, yet he absorbed into his being the great traditions of his hospital. In Johannesburg he became a pillar of South African surgery. A nation asks of its surgeons that they shall be wise, honest, and skilful; Beyers was all of these, and he was also human and kind. When he died before his prime he left a company of colleagues who loved him as a man and a multitude of patients who owed their restored health to his skill as a surgeon.

Beyers has left behind him a great record and a great example. South African surgery stands very high in the world to-day, and you have in this city of Johannesburg men whose reputation is international, men who spend their days in constructive work and their leisure in writing. A sermon in praise of idleness by one who comes to you from the more leisured atmosphere of an older country may therefore be opportune.

Proper Use of the Mind

We pride ourselves that we live in the age of science. The scientific method, based upon observation and experiment, was the intellectual habit of the Greeks. It vanished in the Dark Ages, swept away with beauty and culture by the barbarian tidal wave that swamped Europe. It reappeared with the Renaissance and has progressed ever since.

The scientific method has led to the unparalleled advance of medicine since the time of Harvey; it has, however, the limitation that it is worked by the human mind, a machine subject as all machines are to individual tricks and idiosyncrasies. Yet whereas the mind can make due allowance for faults when they are found in machines other than itself, towards its own faults it is apt to be blind, particularly when it is driven, as no machine should be driven, without rest periods for inspection, adjustments, and renewals.

Man insists on the alternation between work and idleness in the creatures of his own hands and brain. He plans to lay aside his cars at stated intervals to adjust the effects and to replace the ravages of wear. He applies the same principles to his fellow men. The Mosaic Law enjoined one day's rest in seven. Modern conditions, however, tend to interfere with this alternation between work and rest, particularly between mental work and mental rest; for, while the body cannot be driven beyond a certain point without rebelling and ceasing to function, the mind works with no measurable metabolism or consumption of energy, and can go on working without rest, further work often providing the stimulus to greater effort, till the bearings of the machine melt.

What we have come to call civilization has upset the proper use of the mind. In olden days men were individuals. Each man learned from his parents, his fellows, and his elders, but his thoughts were his own thoughts, worked out by him from his gleanings, from his observations of the sky, the sea, the trees, and the animals, into a personal store of knowledge and opinion. Each man worked for a master, but he received his task in the rough to work out according to his own ideas. The journeyman builder was given, not a blue-print to follow slavishly, but a piece of stone to shape into a pillar that should fit one corner of the church that was rising in the meadow, and if he was instructed to decorate the capital he was free to work out a design that included his favourite dog or a caricature of his foreman. Throughout the day his mind was engaged on varied and interesting tasks, and at the day's end it needed and valued rest.

Nowadays men are not asked or encouraged—indeed, are seldom allowed—to think. Their growing minds are

*The Beyer Memorial Lecture delivered at Johannesburg on Nov. 24, 1948.

moulded at school on Government-sponsored primers, and thereafter they receive their opinions from books or newspapers. Their work is no longer personal or intelligent, but some small portion of a whole of which they have no conception, repeated without the use of any mental process several times a minute for fifty-five minutes in the hour, eight hours in the day, five days in the week, and eleven months in the year.

Such a mind is permanently idle, and to it idleness does not mean rest. It has not been weaving patterns from rough materials, but has remained passive while ready-made and standardized patterns, mass-produced on the cheap to fit cortices of every grade and every race, were scribbled over it. When not so used it has no means of self-employment, no stores to lay down in the basement; and the primitive instincts of the herd—love, fear, hate, and greed—stir dimly in those caves of instinct and produce mass sentiments masquerading as thought, clichés and catchwords that form the conversation and the wit of the moron.

The active mind, on the other hand, may be working all the time and come to no harm if the work is congenial, interesting, and within its trained capacity. The artist can paint for hours without being aware of the clock; the surgeon can perform a four-hour operation of the greatest intricacy, at every stage of which he has to make decisions of prime importance, yet he feels no fatigue. But let the artist trudge round a picture gallery, or the surgeon try to watch a colleague for four hours, and both of them will be calling for a Guinness. The mind can work thus continually without tiring, and do so day after day, but it is not doing its best work. It is making decisions without storing them, collecting pictures without hanging them in the galleries, laying up a hoard of valuables which become treasures only when they are sorted out in relation to each other and properly displayed.

Constant use of the mind does not lead to exhaustion any more than constant idleness leads to refreshment. What exhausts is effort rather than use, the performance of tasks that are distasteful or that are beyond easy fulfilment, the fear of failure because the training is inadequate, the intelligence insufficient, the experience too small and too recent. Even so, an internal-combustion engine suffers little harm when it is run for long hours within its capacity or for short bursts at full speed, but when it is constantly set to do the work of a larger engine by operating at full load for hours on end it very soon gives out.

The Cerebral Cortex—the Last Refinement

But a simile that likens the human mind to a machine is over-simplified. The part of the brain that is machine-like is that part whose pattern was designed in the dim evolutionary past, the part that functions automatically while life lasts, whether the owner is directing those functions or not, whether he is asleep, drugged, or engaged in other business. We know that cats or dogs deprived of their cerebral cortex are still cats and dogs with many of their qualities intact. The dog has lost his affection and the cat his aloof cynicism, but both can run about the room in a manner that differs little from normal. Both can show fear and rage. The age-old machinery of the ductless glands, acting by a mechanism of chemical conduction that is but a refined version of the way in which the amoeba finds its food, the autonomic nervous system that recalls the central nervous system of the earthworm, the central ganglia standing at the head of the spinal cord like the cerebral ganglion of cyclostomes, will do all or nearly all that we need to do without conscious attention from us. They will breathe for us, keep our hearts going at the

required speed, adjust our circulation, look after our digestion; they will, with barely conscious guidance, conduct the intricate balancing movements required to ride a bicycle or the complicated calculations that tell us which foot will reach a bar fifty feet ahead when we are running for a long jump. The cerebral cortex, that gives a consciousness to the sorrows, hopes, and fears arising at these lower levels, is the last refinement, the part in whose development we pride ourselves as possessing something that distinguishes us from the lower orders of creation, the part whose highest advancement is the distinguishing mark of the man who stands above his fellows.

The old machine supplies the power, the cerebral cortex determines the direction and length of the journey and its speed, but the two functions of the mind—control and power—vested in different parts of the same machine, can never be entirely distinct as are a driver and his automobile. The driver may step out and go indoors, and while he is away the machine is at rest. The cerebral cortex relaxes its control during sleep, but the subcortical brain is ticking over in the garage, and at any time it may spring to life and race away. And when some part of the operating mechanism takes charge—fear, hunger, or, most dominant of all, sex—the machine is off at top speed and the owner must jump into the seat, seize the wheel, and do his best: he is in for a ride over which his control is not much more than illusory, a ride that may thrill him or lead him to disaster.

What We Lack To-day

When we sigh for the good old days we are immediately reproved by the social reformer, the politician, the statistician, and the leader writer. We are told that there were no good old days; that these distant periods are gilded for us by the mists of time and by the tendency of onlookers to mistake picturesqueness for happiness; that the fortunate few lived in luxury while the workers were poorly clothed and poorly housed, having none of the pleasures that the working-class enjoy to-day, uncomplaining because they knew no better. On the other hand we make a great mistake if we think that happiness consists in having a forty-hour week, a smart car, a television set, and a chromium-plated bathroom. Happiness consists in a job that provides a succession of varied and interesting tasks that demand skill and call for individual enterprise, that is useful to the community in which we live, that offers security if we do it conscientiously and advancement if we do it well, and, if not a belief in a future life, at any rate a confident belief in the future that this life holds for us. All these things the craftsmen and peasants of the Middle Ages had. All or nearly all of them we lack to-day.

The world is no longer full of opportunity. The adolescent must study the openings in a number of trades and finally choose one, knowing that he is on a path that he must follow for the rest of his days. He must work hard and wait long for advancement, which is the reward of uncomplaining waiting rather than of merit. And he is prevented by class and family pride, by the wish to start where his father left off, from making a home and starting a family till long after the age when such occupations are instinctive and physiologically desirable. Later we see him still more unhappy, frustrated because the chance for which he has been working has still not materialized, unable even to confess his fears or share his disappointment because both he and his wife have lived their own lives and put their own interests first for so long before they married that they have been unable to establish that mutual confidence and self-sacrificing comradeship that is the basis of happy marriage. Such men are, in the words of the old song, "all dressed up and no place to go." They have been

ining so long after achievement that strain has become and nature. They are so constantly keyed up to fight world that is trying to tread them down that they are a state of continual and futile preparedness. Their basal ganglia are tuned for combat in the day and rehearsing combat during sleep. Their autonomic system is driving its digestive mechanism beyond the needs of appetite and driving their metabolism at a level they do not really require. The mechanisms that are being called into play are all normal ones; the only abnormality is that they are being led on constantly. It is unlikely that any organ or system the body ever works anywhere near to capacity. The number of nephrons in the renal system is reckoned to be five times that required for normal excretion; it is probable that they work in turn and rest in turn. The brain, all organs in the body, shows perhaps the greatest surplus functional matter over requirements of function. Body and mind seem to have been designed with a tremendous reserve of essential machinery, so that in their normal work—labour and rest may alternate. In modern life they are forced to work abnormally.

Stress Diseases

These are the conditions under which a great proportion of the inhabitants of the older and more civilized communities live, and these are the conditions that are causing them to break down and are producing a group of diseases that we may call the stress diseases. In the less stoutly built it is the mind itself that gives way. In the more stable mind remains coherent and calm and the mechanism working beneath it cracks under the strain. The primitive basal emotions that reside in the basal ganglia take charge. The autonomic and endocrine arsenals pour out their emissions to excess.

Three diseases stand out as striking and universally acknowledged examples of stress casualties: thyrotoxicosis, peptic ulcer, and non-renal hypertension. These diseases, however, become a group that have a similar origin, have certain features in common. They were relatively rare till the beginning of the present century, but since that date their incidence has increased progressively. They are found in civilized countries, in the urban and industrial areas of those countries, and among the more intelligent, ambitious, and hard-working members of the communities. They are seldom encountered in the placid and the lazy, and are practically unknown among native races living under natural conditions. They are thus diathetic or psychosomatic diseases, disturbances of the normal relation of mind and body under overpowering circumstances, and for that reason calling for some general remedy. Yet at present all, except in their earliest stages, appear to be best treated by surgery of a somewhat crude nature. The rational aim of surgery would be to intercept one of the torch-bearers between the hypothalamus and the final recipient in the body tissues. This, unfortunately, is rarely possible, and we must endeavour to correct the defect in the final recipient tissue itself (see p. 648). Our treatment is thus local and destructive. It involves some part only of an activity that is essentially widespread, and tackles a manifestation rather than a cause of the disease; but nevertheless it leads to an improvement that is more satisfactory and more lasting than that produced, in the present state of our knowledge, by any other means.

Of all people we surgeons are most prone to these diseases. I can hardly claim that we are more intelligent, more ambitious, and hard-working than any other section of the community, but we certainly shoulder as great a responsibility and must undergo as great an anxiety as any, and so long and so steep is the ladder to advancement, so many

the hands that clutch at its rungs, that we suffer frustration as an occupational risk. Acute hyperthyroidism is distressingly common, and apparently on the increase, among young medical men, usually those holding junior staff appointments and trying to stretch a slowly growing income to cover the needs of a rapidly growing family. Duodenal ulcer is the disease of the surgical registrar and junior surgeon, and an unannounced visit to the surgeons' room at any hospital will usually surprise one of the staff swallowing his glass of citrated milk and his alkaline tablet between operations. Hypertension affects surgeons in their fifties, and makes them one of the worst occupational risks from the point of view of insurance companies.

Rest Periods

To what extent are these risks avoidable? The young man who has carried all before him in his medical school, who has good brains, clever hands, and a stout heart, would be a traitor to himself if he did not plunge unafraid into the battle, prepared to give and to take hard knocks till he has won through. But when he has so won, when the clash of steel sounds fainter behind him and he stands bloody and unbowed with a few comrades equally tough on the upper slopes, he is apt to keep the same combative outlook from mere force of habit, to go on fighting for fighting's sake and working because he has never done anything else. It is this prolonged and no longer needed exertion that is harmful. It is unfair to all those cultural sides of his nature that have had to be laid aside for a time. It is unfair to his wife and his family. It is bad for his thyroid, his adrenals, and his cardiovascular system. Above all it is bad for his surgery.

It is to an audience of medical men, above all to an audience of surgeons, that a sermon in praise of idleness is necessary. We have seen that idleness is a part of function. The heart gives one gigantic heave that sends a dose of blood racing along the aorta; but systole lasts only one-third of a second, and for twice as long the heart takes a rest. A meal is followed by a period during which the stomach and proximal small intestine take the food down to its elemental components, pancreatic, and intestinal juices and the proximal colon absorb.

very much the same way. Impressions are constantly being received by the eyes, the ears, the nose, and the hands. Some of these produce momentary reactions and are gone. Some, repeated or received with special strength, are laid down in the association centres as memories. But for the best use of these impressions it is important that there should be periods when the mind has nothing to do but look over its stores and sort them out.

We can recognize among our students two types. At one extreme we have the overpowering enthusiast who attends all lectures and takes down every word from first to last. After a hurried meal he goes to the library and pores over a textbook till the time comes for a ward round, when he listens eagerly to every comment and again enters it in his book. At the other extreme is the footballer who strolls into the lecture a little late and does not really get into his stride as a listener till he has filled and lit his pipe and gets it drawing to his satisfaction. His notes are sparse, and at rounds he is attentive but not verbose. Yet when it comes to a practical task the second one approaches it with a common-sense outlook; when he is asked a question whose answer is not in the textbook he is able to see through the problem to its essentials and give an answer that may not be the right one but that embodies his personal experience; at examinations he beats his more studious fellow student, in the practicals at any rate, and when he goes into the world he makes a better doctor.

Most of us have passed through both of these phases, through spells of hard conscientious work and through spells of idleness. In the first we have acquired knowledge; in the second we have built up wisdom. In the first we have been worthy workers. In the second we have made, or started the train that has brought us to, those personal contributions by which we hope to be remembered when we are dead. For the human mind which has been driven hard does its best work when the tension is outspanned and it is allowed to find the natural paths that shape themselves in idle periods.

For many of us the war has provided such a sabbatical break. We have worked hard even in uniform, but for long times we have remained idle. Then it is that we have discovered to our joy that the disconnected visions of our student days are all fitting into a pattern. Figuratively, we have sprung like Archimedes from the bath in which we have been dozing and have shouted "Eureka."

I have enjoyed such periods of idleness more than most members of my profession. Since I became a surgeon I have twice been docked for six months for repairs—once after an illness, once after a motor accident. In addition I have spent more time in the forward surgery of war than any man. And war is the ideal alternative between feverish activity and leisure, between times when ideas crowd upon us and times when they can be worked out. It provides the tremendous stimulus of corporate loyalty, it brings the fundamental problems of injury and infection once again before us, and it gives us abundant opportunity to study them. Throughout my life I shall remember the entry into Addis Ababa in April, 1941, when I sat next to Dan Pienaar drinking the Duke of Aosta's wines in the *Piccolo Gebbi*, and the spell of idleness that followed in that grand and barbarous country. I shall think of weeks in the Western Desert when the clear air brought every faculty to life, when the distance at sunset took on every colour of brown, purple, and blue, and at night millions of stars shone with a brightness that seems to be seen only in the Egyptian sky.

Those happy days are past, but now, after three years of hard work in civil surgery, I have once again enjoyed the pleasures of idleness, the armchair existence of a five-days flight in a Plymouth flying-boat. And as it is the most

recent arrivals in the aerodromes of the brain that are still circling the association centres looking for a suitable strip on which to land and night-stop, so it is that the problem of these stress diseases have been turning over in the recesses of my subconscious mind seeking their own clarification while I have been consciously looking down on that wonderful panorama of alternating arid waste and prodigal fertility that is Africa.

Thyrotoxicosis a Stress Disease

That thyrotoxicosis is in most cases a stress disease few will deny. As the thyroid is particularly linked up with the female sexual and reproductive cycle, thyrotoxicosis is above all a stress disease of women, and seems to have its origin most frequently in some emotional disaster connected with a love affair. It is, however, by no means unknown in men, and I have met it several times in the war in young officers summoned to take high rank and responsible posts and asked to bear a load of authority beyond their years. It differs from the other two stress diseases I have mentioned in that, once started, it is self continuing, and no amount of idleness, no change of occupation or psychological adjustment, has any power to stop it. Though the thyroid gland is probably fourth in the chain of guilt, the basal ganglia, the hypothalamus, and the pituitary taking prior blame, it is responsible for most of the clinical manifestations of the disease, and in the reduction of its activity lies the only prospect of relief or cure.

The overactive thyroid may be damaged by x rays, poisoned with thiouracil, tricked into its own destruction by radioactive iodine, or pruned with a knife as required.

The results claimed for thiouracil show few grounds for satisfaction or even complacency. The mortality under treatment is at any rate 2%. Ten per cent. of patients are intolerant of the drug; of the remainder only 3% are cured—that is, remain symptom-free for a year or more after treatment has been stopped. The majority must remain for years under observation, with occasional return to a maintenance dose. Two per cent. develop agranulocytosis. In nearly all of them the goitre increases in size it may become cystic and cause pressure symptoms, it may atrophy and lead to myxoedema, it may become malignant. Broders and Parkhill state that "thiouracil goitre is more of a cellular hyperplasia with mitoses very much in evidence, and so therefore more comparable to carcinoma."

The majority of patients treated with thiouracil eventually need operation because their thyrotoxicosis is not cured because they dislike the disfigurement of a large goitre, because cysts or haemorrhages are pressing on the trachea or oesophagus. They present the surgeon with a task considerably enhanced difficulty, for the thiouracil goitre is rigid, friable, haemorrhagic, and adherent, and remains so to some extent even after a long rest from the drug and a course of iodine. On the other hand, the mortality of operation in the hands of a practised surgeon working with a physician who shuns thiouracil is not more than 1%, and the proportion of patients cured—that is, able to return within a few weeks to a full and active life—is over 90%.

I have always felt that an operation secures the desired result more quickly, more certainly, and more safely than any other means, and, having within the last two years like Omar Khayyám, heard great argument about it and about, I still come out by the same door to register my vote in the same lobby: indeed, after a week's reflection in the relative anoxia of 12,000 feet and under the soporific drone of four engines, I am prepared to be almost dogmatic. I hold that thiouracil has had a fair trial and has failed miserably, that it has no useful place in reputable therapy, and that its use should be prohibited except

those cases of thyrotoxicosis where operation has been definitely abandoned or where it must be postponed till after the performance of another and more urgent operation, such as one for cancer.

Of the operation I will touch only on a few points that interest me. We all use the collar incision, but none of us, I hope, use the Kocher incision. The collar incision follows a natural crease and the scar is invisible in six weeks: the Kocher incision is strongly curved, with the ends turned up like the moustache of a bomber pilot, and it leaves the horrible scars that may be seen any day in the streets of many Continental cities. Some of us cut across the infrahyoid muscles, some split them in the midline and retract them; I do the latter for no more than sentimental reasons. I have never seen any ill follow muscle cutting, but I do not believe access to the poles is helped appreciably thereby, for the first step in subtotal thyroidectomy is free mobilization of the gland by division of the subcricoid connective tissue fan that binds the upper border of the isthmus and the inner border of the two upper poles. I do not expose the recurrent laryngeal nerve, because I believe that to bare so fine a structure is to invite late involvement by scar, and because if I tie the inferior thyroid artery half an inch away from the gland and then cut in front of its branches in the sagittal plane I know the nerve is safe. I have not drained a thyroid for ten years. Drainage for bleeding is unnecessary, for no thyroid wound should be closed till haemostasis is beyond doubt. Oozing of serum may occur, for Nature abhors a vacuum and she abhors catgut even more, but when it occurs it occurs too late for a drain to help, and it can be removed by aspiration without disturbing the scar.

Duodenal Ulcer

Duodenal ulcer, again, is a stress disease. It is predominantly a disease of men, but it is getting commoner in women as they adopt men's clothes and habits and take their jobs; and whereas twenty years ago females formed no more than a tenth of any series, they now contribute a fourth. Unlike hyperthyroidism, duodenalism can be alleviated and occasionally cured if the stress is relieved and its source removed before scar tissue has converted the lesion into one incapable of satisfactory repair; but since to relieve stress in any particular case it may be necessary to change the man's business, to double his income, to stop his cigarettes, or to shoot his partner or his wife, cure by medical means is not always possible. Surgery is thus called on increasingly for the treatment of duodenal ulcer; but it can never provide a cure for the underlying stress, and must be looked on as no more than a treatment of complications. It is a good working rule that no duodenal ulcer patient should be sent to the surgeon until he is 45, or until perforation, stenosis, recurrent major haemorrhage, or constant pain in spite of treatment makes operation inevitable.

Whereas in gastric ulcer any operation that removes the ulcer and the scar around it is usually satisfactory, in duodenal ulcer no operation that does not permanently reduce the level of acid secretion to one of 20% N/10 NaOH or under is likely to give more than temporary relief or provide any safeguard against recurrent ulceration.

I hope I may, without further discussion, dismiss gastrojejunostomy and all forms of pyloroplasty as unsuitable for anything but a very old stenosis in a man old enough to die of natural causes before he gets a jejunal ulcer. I will dismiss vasoligation as summarily, for it is only necessary to visit the two places where it has been practised longest—Manchester and India—to learn how worthless it is. Two operations remain to be discussed—vagotomy and gastrectomy.

Vagotomy

Vagotomy comes to us with all the glamour of the laboratory and the personal recommendation of 57 professors. As I sat in the plane turning over the journals that the steward brought me I was constantly confronted by the advertisement of a face cream that was the final product of years of research and was now acclaimed by Hollywood stars and Mayfair beauties as the source of their loveliness. I seemed to recognize an old friend in Africa: "Vagotomy, I presume."

That vagotomy will reduce the volume and acid level of the gastric secretion in dogs, that it will stop the pain in all peptic ulcers in human beings and heal the majority, for a time at any rate, has been demonstrated beyond question. That it is a sound procedure, to be regarded as the first line of attack on the peptic ulcer problem, is as yet unproved.

A fundamental question that remains to be answered is how important the vagal mechanism of gastric secretion is in human digestion, and what part it plays in the aetiology of ulcer. Dogs have characters and habits very much like those of man—according to the French proverb, better; but they eat with a speed and an enjoyment that we can never hope to emulate. For them vagal secretion is all-important, for it provides an acid bath into which the eagerly awaited and hastily bolted meal drops. Men by custom turn their minds at meal-times to business or to love—in fact, to anything but food; they eat slowly, and the food remains in their stomachs for two hours or more. They need a vagal secretion for the first course, but they depend largely upon a hormonally activated secretion for the further digestion of their meal. Peptic ulcer patients differ from the normal not so much in the high level of their acid secretion as in its constant flow, which has no reference to the calls of meals. The fault with them is not that their acid is too high, but that it is poured into a stomach unbuffered by food.

Vagotomy cuts out completely the psychic flow of gastric juice, but it does nothing to abolish the chemically induced flow that comes later. If there is an ulcer it does not remedy the complications of that ulcer—the stenosis, the deformity, the fixation to surrounding structures; on the contrary, by diminishing gastric tone and delaying gastric emptying it precipitates the stasis which may still be latent, so that in most cases a short-circuit must be performed in addition to the vagotomy to prevent it. Once a fresh opening has been made the stomach is liable to be empty while the second uncontrolled wave of acid secretion is mounting, so that the new stoma is subjected to the dangers of unbuffered acid. In addition to these serious defects vagotomy brings in its train certain minor disabilities, belching and diarrhoea being the most constant, and now that results are coming to light it is clear that it is followed by recurrent ulceration more commonly than a well-performed gastrectomy. Vagotomy is certainly a simpler and, in the hands of those who should not be allowed to do major surgery at all, a safer operation than gastrectomy, but among competent surgeons it will probably come to be reserved for three groups of cases: for patients who have a return of pain or of ulceration after a radical gastrectomy well performed, for cases of gastro-jejunal ulceration to stop pain and bleeding and allow the patient to be made fit for a permanent reconstruction, and for old men with duodenal pain quite out of proportion to the very moderate ulcer that seems to be causing it.

Gastrectomy

Gastrectomy, on the other hand, is a big operation, and, when performed for duodenal ulceration, a difficult one. Yet it gives results that for excellence and permanence are

as yet unrivalled by any other method of treatment. To ensure such results five criteria must be satisfied:

1. The whole pyloric mucous membrane in which the secretory hormone is produced must be removed.
2. The acid-secreting mucous membrane must be ablated in those regions in which it is thick and rugose—that is, in the body of the stomach.
3. The lesser omentum must be divided right up to the cardia, in order to divide the left gastric artery at its origin and allow the lesser curve to swing free, and to interrupt the majority of the vagal fibres.
4. The stoma between the remaining stomach and the intestine must be no larger than the bowel into which it empties—that is, about $1\frac{1}{2}$ in. (3.75 cm.) in diameter.
5. The passage of food after leaving the stomach must be in an onward direction only.

None of the last three requirements is satisfied by the conventional Polya gastrectomy; all are fulfilled either by the modern Billroth I gastrectomy or by the valvular Billroth II gastrectomy.

Hypertension

Hypertension is not a new disease. It has killed many of the great men of history. Non-renal hypertension, or hyperpiesia, on the other hand, is a new disease and a stress disease. It is the price the millionaire pays for his directorships and the clerk for his failure. Its aetiology is unknown. A similar condition can be produced in dogs by clamping the renal pedicle; but, though in some instances human hypertension is associated with one damaged kidney and cured by its removal, such cases are curiosities; in most the renal function is normal, and the kidneys become involved only late in the disease.

The surgery of hypertension provides to-day one of the most interesting subjects for study and one of the most fascinating topics for discussion. Study is stimulated whenever a new problem appears or when a new discovery throws fresh light on an old one. Discussion is most enthralling when theories abound but proved facts are few.

Operations for the relief of the more distressing symptoms of hypertension are being performed in every country. You have done many here. Papers have appeared from the pens of many leading surgeons. You in Johannesburg have contributed some of the most interesting of them. I have done some operations myself, and was one of the first to do them in Britain, but I have spent far more time watching the work of others, reading their papers, listening to their discussions. And I speak to-day as one off duty, voicing those questions that disturb my idleness because I do not know the answers.

What is the cause of essential hypertension? I do not know, and if anyone does he has not told me. What justification is there for attempting to cure by a major operation a disease about which we are so ignorant? The justification of results: surgical treatment is admittedly empirical, but it does cure or improve patients who would otherwise get worse or die. In what way do we believe that blood pressure may be lowered by operation? Once more we do not know, and each surgeon has a different answer and modifies his operation according to the aim he has in view. There are at least five ways in which it may be suggested that the blood pressure can be lowered by operation on the sympathetic system: (1) by dilating the vessels of the lower limbs; (2) by dilating the vessels in the splanchnic bed; (3) by denervating the kidney; (4) by denervating the adrenals; (5) by dividing the sympathetic fibres to the heart.

Merits of Operation for Hypertension

What are the results of operation? Relief of the more distressing symptoms in nearly all cases; prolongation of

life in any series in comparison with a similar series untreated or treated medically; temporary lowering of blood pressure in many, permanent restoration of blood pressure to normal in a few. Can we select those most suitable for operation, or judge beforehand by tests the extent to which any patient is likely to benefit? No. Tests are so fallacious that many have abandoned them. Can we judge from the figures published by surgeons which of them is getting the best results? No; because surgeons differ fantastically in their selection of cases for operation and in their assessment of post-operative results. At one extreme we have Professor X., who will operate only on patients under 40 who have normal renal function, no eye changes, and show a good response to sedation; he has no operative mortality and a high cure rate, but many of his patients might have got well anyway. At the other end is Professor Y., whose chief indications for operation are progressive headaches and failing vision, and who is undeterred by poor renal function and doubtful cerebral and coronary circulation; he has a number of operative and still more post-operative deaths, and most of those who survive are dead five years later, but he saves untold misery and adds some months of productive life to many useful citizens.

The two most popular operations to-day are the Smithwick, in which the three splanchnic nerves and the sympathetic chain from the eighth dorsal to the first of second lumbar ganglion are removed through a trans-diaphragmatic extrapleural approach; and the transpleural, in which the thoracic chain from the fourth dorsal to the first lumbar ganglion, and the three splanchnic nerves in their thoracic portion, are removed through a wide thoracotomy opening. The anatomical reason for this lengthy ablation is that sympathetic fibres have been shown to leave the upper thoracic chain and travel down to the coeliac plexus on the aorta without traversing the splanchnic nerves.

Now I am going to take courage, from the fact that Edinburgh and Manchester are five thousand miles away and that Boston and Ann Arbor are seven thousand miles away, to voice a few beliefs and disbeliefs.

I believe that an operation for hypertension is effective chiefly in so far as it denervates the kidneys and adrenals, and that the vasodilatation it produces is variable in amount and secondary in importance. I do not believe that there is any significant difference in the relief of symptoms and the lowering of blood pressure obtained between a thorough subdiaphragmatic denervation and a Smithwick operation, or between either of these and the extensive transpleural operation now fashionable in England. I do not attach much importance to filament-chasing, nor do I believe that nerves ever regenerate across gaps; at any rate they are never known to do so when we want them to.

Holding these views, I cannot muster any enthusiasm for the Smithwick operation. It is a Peet-Adson hybrid. It often damages the diaphragm and holes the pleura, and it does so to no purpose if it gives results not differing appreciably from the subdiaphragmatic operation. Still less can I grow lyrical over the transpleural operation, which is less thorough than the Smithwick at the lumbar end (I believe the more important end) of the sympathetic chain and is more thorough chiefly in dilating the intercostal vessels. I doubt whether the aortic filament is more than an anatomist's bauble and whether a knowledge of its occasional existence should persuade us to adopt an operation that is not demonstrably superior to others and that is followed by severe pain in the incision in quite a large number of patients. Though I am fully aware that I risk censure by the high priests of hypertension, I will state my own views, which, I reiterate, are those of an idle man, of

one who leans over the railings watching others digging a hole in the road and sees where they are doing it wrong.

Personal Views

First I should accept my cases only from a medical colleague. There are many things other than surgery that may cure hypertension. I well remember George Heuer, of Cornell University, relating two such cases at the meeting of the American College of Surgeons in New York in 1938. Both patients had hypertension that had proved refractory to every form of treatment and had been selected for surgery. One had a serious motor accident on the way to hospital; the other collapsed under the anaesthetic after the laminae had been removed but before any nerve roots had been divided. Both were cured. Rather than choose my cases myself, therefore, or rely on any form of test, I would take only those that had been under the care of a wise physician and accept his judgment that no change of occupation and no drug treatment could help them.

Secondly, I should refuse none except those with myocardial changes. The man who needs a high pressure to push blood through his coronary arteries will die the minute it is lowered. The others—those with poor kidneys, with a rising blood urea, who are unable to work because of their headaches, who are going blind—are also poor operative risks. They are no good to the surgeon whose eye is on statistics. On the other hand, they need our help more than any, and we can promise to help them. Their world is falling in ruins round them. We may send them prematurely to the next, but if we do not we give them a joy they had ceased to hope for. And the improvement seems to be largely unrelated to the fall in blood pressure. An operation that, judged by the sphygmomanometer, is a failure may yet relieve the patient of all his distressing symptoms.

Thirdly, I should, as my main line of attack, perform a bilateral subdiaphragmatic operation through an incision resecting the twelfth rib. I should resect the sympathetic chain from the third lumbar to the twelfth or eleventh dorsal ganglion, following the chain up by splitting the crus. I should pick up the splanchnics where they leave the diaphragm, divide them where they enter the semilunar ganglia, and follow them as high as I could through the diaphragm before cutting them again. I should do this operation on one side, and if the anaesthetist reassured me I should then do it on the other; if the drop in blood pressure was considerable I should do the second side three weeks later.

Fourthly, I should send the patient home after he had recovered from the double operation and reassess him after three months. If it seemed advisable to lower his blood pressure still further I should attack the cardiac sympathetic fibres by removing the second, third, and fourth dorsal ganglia, first on the left side, later, if necessary and after an interval, on the right. I should not divide the diaphragm nor should I open the pleura.

Well, gentlemen, I have talked so long of idleness that I have exhausted you. I have strained your patience so much that your pressures must be near to apoplexy and your duodenal ulcers to perforating. My thesis is the very simple one that the man who works hard and conscientiously does his most important work when he outspans his mind and allows it to wander at its own pace round the paths over which it has been rushing, and that science is advanced further in a shorter time by the informal chatter of a few like-minded friends over cocktails than by the formal exchange of papers or by any number of congresses.

The figure was planned by my former House Surgeon, Mr. Alan Parks.

THE DISCOMFORTS OF CHILDBIRTH*

BY

GRANTLY DICK READ, M.A., M.D.

When I was a student "on the district" I attended a girl whose reaction to childbirth greatly impressed me. When the head started to crown and the effort syndrome became obvious, with the evidence of suffering, I offered her such anaesthetic as I was allowed to give, and she would not take it, but between the contractions she smiled happily. After her baby was born I inquired why she would not take any anaesthetic freely offered her, and her reply has always remained in my mind. She did not take her anaesthetic because she did not want it. "It didn't hurt, doctor," she said; "it wasn't meant to hurt, was it?"

From the teaching of Crile and Head it became obvious to me that the discomforts of childbirth depended largely on the emotional and not solely on the mechanical factors which one had been taught were the cause of the pain. The fact that in childbirth there is usually a woman present is not always remembered even to-day. The performance of the mechanism of parturition is undertaken with a magnificent apparatus, but the fact that the woman has a brain, a mind, an extremely sensitive nervous system from which the impulses act and react upon the mechanism, is not so freely understood.

I asked myself how a woman could be expected to be successful in the task of bearing a child if she was not equipped with adequate knowledge. Would it be expected that the secretary of a business man would be successful if she had never handled pencil and typewriter? Yet women are allowed to enter upon the most important task of their lives untutored, untaught, and unassisted. I began, therefore, to educate my patients much earlier in pregnancy. From the time the women came to report that they were pregnant they were tactfully, gradually, and carefully initiated into the job they were about to perform. Their preparation included not only the normal clinical care of the antenatal clinic but they were taught relaxation and respiratory exercises, and during their short periods of rest while they were under instruction they had the art of childbirth explained to them. They were told that they had a uterus in which the baby was growing, that the uterus was made of muscle and grew with the child, and at each visit they were told the relative size of the child. They were told that the child would move and how to expect to "feel" their baby at about 17 or 19 weeks, as the case might be; they were told the position and were even shown a diagram of it. They were also told that they were already feeding the child and that it was necessary that they themselves should take some care of their own diet. They were told what they should eat and what they should not eat.

My patients were delivered on their backs, propped up in a position equivalent to squatting, but leaning, because the average European is not accustomed to squat. They held their child's hands before the baby was fully born and took it in their arms as soon as the cord was severed. Their happiness and complete freedom from pain were remarkable. Their refusal of anaesthesia was noted, and not infrequently they scorned and rejected the idea that they should be unconscious at such a great moment.

Nerve Supply of the Uterus

The neurological explanation of the phenomena I was witnessing was important. Some years previously Beckwith Whitehouse, in Birmingham, had worked very seriously on

*The substance of a lecture delivered before St. Mary's Hospital Medical Society on Oct. 28, 1948, with Dr. G. W. B. James presiding.

the nerve supply of the uterus. He came to the conclusion that the different muscle fibres of the uterus lying in different directions were supplied one by the autonomic nerves and the other by the sympathetic nervous system, and that these groups worked in harmony in much the same way as opposing muscle groups work in harmony—that is to say, when one group contracts the other relaxes. That is the mechanism whereby the expulsive muscles of the bladder and rectum and the corresponding sphincters work. With the release of the sphincters the expulsive muscles come into play. With the nerve supply of the uterus it was the same story. The circular inhibitory fibres should be relaxed, loose, and acting in harmony with the expulsive longitudinal fibres whose enormous power at full term is sufficient to dilate the cervix for the child to pass through, when the dilating force is augmented by the great effort of expulsion to drive the child through the birth canal.

Thus again the story of Head's thalamic pain loomed very largely into the picture. If in the presence of fear, as Crile and others had pointed out, the sympathetic nervous system throughout the body created a state of tension—a great protective activity to fight or fly from that of which it was afraid—the fear of labour would bring about rigidity by sympathetic nerve-fibre stimulation and the muscles and organs supplied by that nervous system would also be in a state of tension. The outlet of the uterus would be relatively rigid and the cervix resistant to dilatation. Thus there would be tension not only in the person herself but also in the apparatus of reproduction. The presence of fear is therefore a direct cause of somatic manifestation giving rise to the real pains of labour. Sir Charles Sherrington found that the uterus had only two pain-recording nerve endings—those which recorded laceration and those which recorded excess of tension above the normal mean.

Put those simple observations together and see what we have. In the presence of fear the outlet of the uterus is in a state of chronic contraction. The longitudinal fibres of the uterus struggle to release or burst through that resistance of the circular fibres of the uterus, increasing enormously the tension within the organ itself and thereby stimulating the receptors of pain. It is very simple and far more important therefore to remove the fear and the tension, for thus the amount of suffering in labour becomes negligible in comparison with that endured by the woman who is afraid. It is not enough for the woman to say, "I am not afraid." There are subconscious fears, fears formed and based on past associations or ideas. If these can all be removed then the labour of the human female becomes as easy and as enjoyable, in spite of the work and effort involved and the call upon her higher qualities, as it is in the lower animals.

Emotional Phases

But that again is not enough, and in order to understand exactly what emotional changes occur in labour we must study a labour which is normal—that is to say, a labour in an unanaesthetized woman, where the natural function is carried out without interference. It became possible to study these labours in large numbers when this series of events was implemented, when the fear was removed, and when the woman herself was in a natural state of relaxation and had no desire for anaesthetics or sedatives, for which, indeed, there was no necessity. Thus the study of the normal emotional phases of labour became possible, and, perhaps more interesting than anything else, in this idea was the discovery that labour is not a purely mechanical affair at all, but is closely associated with varying emotional phases. The chemists will shortly, I hope, be able to prove

and demonstrate to us that many of the chemical constituents of the body vary with the emotions during labour. Particularly is that true of the blood sugar, as well as other biochemical factors.

But it is necessary to show how these emotional phase can be recognized, because one cannot conduct a labour to the full satisfaction of oneself and of the mother (and I am beginning to believe, of the newborn child) unless one understands more than the purely mechanical function of parturition. It is not enough to wait until the head is showing and then put on a mask and gown and get a friend to give some "dope" and stand at the other end of the bed. That is not obstetrics, but it still goes on. Obstetrics is the understanding of the mind as well as the body of a woman in order that she may produce her child in the most natural way with the least injury to both mind and body—certainly the minimum of injury to the mind.

First Stage of Labour

The first stage of labour is the stage of initiation and expectancy. The antenatal anticipation of labour is a very boring time. There is no more trying period in a woman's life than the last two weeks during which she is waiting for the baby to be born. She not only wants her baby but she wants to get rid of the pelvic burden and to be again a freely mobile person. Women will go into labour in a condition of considerable exhilaration and animation, and until the cervix is dilated to between one-fifth and two-fifths (I am speaking of the primiparous woman) they will retain that state if there has been an intelligent and proper approach to labour.

When the cervix dilates further there occurs a very marked change. At two-fifths dilatation the large majority of patients will offer two manifestations. They will become quieter, although cheerful between contractions, and they will develop a pronounced malar flush. I would look for the malar flush appearing on the woman's face at two-fifths dilatation, because one knows then that the labour is truly progressive. The woman then begins to realize that she is completely helpless in relation to her uterine contractions. She is in the power of forces over which she has no control. Mere man would be alarmed under those circumstances, but woman fortunately has a better mentality.

When the uterus gets to three-fifths dilatation the woman has become serious in her demeanour—I do not mean distressed—but many of them are uneasy in their minds. What they desire is company. It is not physical pain which gives rise to the distress at three-fifths dilatation. It is the first emotional menace of labour. That can be diagnosed clinically perfectly well, and it is at that time that the woman should be left alone. There is no greater obstetric crime than to leave a woman in a room by herself at three-fifths dilatation and tell her, "You are not going to have your baby for perhaps ten or twelve hours. We have no time to look after you. Do not make a lot of noise, and we will come and see you from time to time." That is the way to ruin a woman's labour—indeed, a way to ruin her whole life, for pain and terror beyond control will give psychological foundation to future experience that even time will not rectify.

If that phase is well cared for she will carry on with assistance and regain considerable confidence before the cervix is four-fifths dilated. This is the time when a sedative should be given, if it has to be.

Second Stage

Then we come to the transition from the first to the second stage. The transition is the great testing period

labour, for then the cervix is dilated to its fullest. Many women definitely have pain at this stage even in the most normal labours, because of the tension brought about at the ultimate dilatation of the cervix. This is the second emotional menace of labour. Here is a true test of the woman's faith and fortitude. It is a period fraught with anxiety and perhaps pain. This is the time in normal labour when there is backache in about 50% of all cases. It should be recognized as the *pain period of labour*, and the average normal labour in which there is any pain will exhibit it at this stage.

As that emotional storm abates the woman will pass into the second stage of labour with the establishment of firm contractions, and she will be astonished at the disappearance of the backache and the sense of tremendous relief at being able to help herself. She will also greatly rejoice in the ability to push her baby through the birth canal, but I do not want to allude to mechanical factors now.

The third emotional phase occurs when the head reaches the pelvic floor. Many women will be inclined to give up their labour at this point. They will complain of all sorts of things; they will show a desire to escape. They will use all their female arts and wiles to persuade their attendants to do something for them. I have seen women full of fear and "suffering the tortures of the damned," although their pulse actually remained at 70, they were not perspiring, and they were breathing freely. The same women have explained to me afterwards that it was not a question of physical discomfort but a terror of anticipation from which they suffered. These women are quite honest with you and tell you exactly what they have felt at this time. One woman obstetrician whom I attended told me after her baby was born that I had not emphasized sufficiently the alarm then felt.

The fourth emotional menace is a real one because it varies with the conformity of the woman. In many women the ultimate outlet of the vulva is elastic, particularly up to the age of 26 or 27. At the crowning of the head, if a woman is in full control of herself, including respiratory control, it is not painful. At ages of from 26 to 34 the indifferent elasticity of the vulva may bring about some difficulty and at about half-crowning there is the onset of a sensation which most women describe "as if they are about to burst." It is not a feeling of actual tension or tearing, but of burning. If you ask them to describe the pain they will say "they are burning or stinging down below."

That sensation has a neurological basis. It is very largely due to the fact that certain nerve receptors go out of action before others (epicritic before protopathic), leaving nociceptors to record certain sensations of vulval sensibility. But this disappears quickly in the large majority of women and there is almost complete anaesthesia of the perineum within one-half to three-quarters of an inch of the vulval margin. There is no sensibility whatever to the tear. There is no pain. The woman feels only a sudden release, and afterwards what appears to be a massive laceration, which if it occurred in any other part of the body would cause considerable pain, has been sustained almost without her knowledge, and she is disappointed when she is asked to submit to the insertion of stitches.

Therefore there are not only the physical factors but four emotional factors which intensify the stimulus. The mind, however, can usually be trusted to take charge of the situation without the necessity for anaesthetics or even sedatives. The more experienced one becomes in these matters the more easily can these emotional factors be controlled. But they are quite definite phases and similar in all primiparae, and can be recognized as discrete entities. In multi-

parae it is a slightly different story, because the whole of a relaxed labour in a multiparous woman is so short that these phenomena run rather on the top of one another. Many women undertake parturition in the spirit which thinks of nothing except having the baby as soon as possible and with the greatest amount of happiness. Labours of two hours are no exception. There is no fear, and therefore only a desire for the child.

Third Stage

The third stage of labour is the only one which presents any anxiety to the normal obstetrician. It is the most difficult to carry out successfully. In a truly physiological labour the mother will be holding the hands of the child before the body is born. The head emerges and with the next contraction the shoulders are freed. The child is then rotated and lies upwards facing the mother. That rotation gives relief and takes the tension from the points where it has been at its greatest on the perineum. It is then we see an astonishing transfiguration of a hard-working woman employing the effort syndrome, which made her appear distressed, to a mother who suddenly becomes happy and smiling and sits up and waits for the baby to be fully born. Women in these circumstances will complain because the doctor is not yet able to tell them whether it is a boy or a girl. They will ask him to hurry, and I have to say to them, "I will hurry when you give me a contraction to hurry with." The sight of the infant brings on various emotional changes which are by some standards exaggerated. They speak of the child with fascinated wonder and enchantment. The most dull woman can burst out in exaggerated terms of delight at the sight of her child.

These children are all handed to the mother immediately the cord is cut. Every woman takes her child in her arms and holds it to her breast, not necessarily to suckle it. This stimulates a reflex contraction of the uterus which is definitely of physiological value. I think women were meant to take their babies when born. They will say what a funny-looking thing it is. "Is that the right colour, doctor?" "It really is like my husband."

Expulsion of the Placenta

Meanwhile the uterus contracts down to a firm solid ball. It is my custom to put a Spencer Wells forceps on to the cord close to the vulva, having a little tension on it, and hand the child to the mother. A basin is left underneath to receive the placenta. Not infrequently, as the mother plays with the child you will see the Spencer Wells drop into the receptacle and the cord lengthen five or six inches. It is not always sound practice to judge the position of the placenta by the height of the uterus. The placenta may be extruded and the height of the uterus not alter very much. But if the cord is seen to lengthen five or six inches, with possibly an ounce of haemorrhage, one may be sure that most of the placenta is in the vagina.

The mother is given a hot drink and the baby put in the crib at her side. Twenty minutes is the minimum time to expel the placenta. During that time while the urge to expel the afterbirth is occurring the happy woman is subjected to another wave of anxiety as the uterus contracts, although she cannot feel anything. One might imagine the expression of anticipation on her face to be an expression of pain. But the passage of the placenta is a source of very great satisfaction. It conveys a sensation which the woman will explain as the end of a glorious episode. The contractions of the uterus are needed for the completion of the function of childbirth, and there is nothing which takes place in childbirth without reason or cause.

Conclusion

Childbirth is being conducted in this manner in many parts of the world. There is no evidence yet that any school which has applied the psychosomatic approach to labour has withdrawn. No man who has understood the emotional has returned to the purely physical conduct of childbirth. There is more in this than the production of the child. At present there is a great wave of fear in the United States of America that the psychological state of married women is so altering that a factor is creeping into society which in a few generations may have a deleterious effect upon the whole nation. Two years ago—when I was in America—I found that the “mind of woman” received little or no care either before or during labour. Now, however, the importance to the mother and baby of this approach to childbirth has been accepted and demonstrated by Professor Herbert Thoms, of Yale University; Dr. Blackwell Sawyer, of New Jersey; Drs. Volmer and Marsh, of San Francisco; the Maternity Center Association, of New York; and others who have adopted these procedures. Their recent publications bear out with remarkable accuracy the conclusions drawn from the work in this country. Complete anaesthesia or unconsciousness in normal childbirth is an offence against Nature. Children who have been born according to the laws of Nature will be evidence of its psychological value as they grow to maturity. It will be easy to recognize those who were born with instinctive maternal guidance in the first few moments of their lives. These factors cannot be overlooked.

In a series of cases recently reported by the first great American university to adopt the procedure here outlined it was stated that 80% of all women—including abnormal labours—were fully conscious of all the sensations of the birth of their babies. I have found that in over 90% of uncomplicated births the women refuse analgesic or anaesthetic. The normal healthy woman of to-day, with a normal healthy labour, will tell you that the birth of her child was “a joy she would not have missed for anything.” She sympathizes with those whom circumstances forced into insensitiveness or oblivion at that moment.

NON-SPECIFIC EFFECTS OF IMPURE PENICILLIN

BY

J. UNGAR, M.D.

(From the Research Division, Glaxo Laboratories, Ltd., Greenford, Middlesex)

It has occasionally been reported during the last three years that impure penicillin is a more effective chemotherapeutic agent than the purified crystalline material. This view was based on the laboratory study of various penicillin samples, using either the protection of animals (Hobby *et al.*, 1946, 1947; Welch *et al.*, 1947; Miller *et al.*, 1948) infected with streptococci, *Bact. typhosum*, or salmonella or the action on the motility of *Treponema pallidum* (Dunham and Rake, 1945). These observations seemed to indicate the presence in crude preparations of penicillin of a factor that increases its antibacterial action; this factor appeared to have so marked an effect on the action of penicillin that the term “enhancement factor” was thought justifiable. This reason probably also explains the suggestion, made in a recent annotation (*B.M.J.*, 1948), to take the retrograde step of reverting to the earlier production methods and the use of impure penicillin.

It should be noted, however, that the data available explain neither the nature of the “enhancement factor”

nor its action (Welch, 1947; Hobby *et al.*, 1947; Fischbach *et al.*, 1947; Pratt *et al.*, 1948). The individual observations are scanty and occasionally conflicting, but this much is certain, that the “enhancement factor” in the impurities is heat-stable, dialysable, and active in small amounts if added to purified penicillin G, K, or dihydro F (Welch, 1947; Hobby *et al.*, 1947). The issue is of importance to the whole problem of presentation, for penicillin may be distributed either as a pure product with specific pharmacodynamic properties or as a crude one in which largely unknown impurities are left. An investigation was therefore undertaken to determine (1) what part the impurities play in the activity of crude penicillin, and (2) the mechanism of any such activity.

With these objects in mind the main work of Welch *et al.* (1947) was first repeated, but using, on a units-per-weight basis, smaller doses of penicillin—just sufficient to protect mice against lethal infections with *Bact. typhosum* or streptococcus, which are those commonly employed in protective trials.

Materials and Animals Used

In this paper we are concerned with a substance or substances that may be present in certain samples of penicillin and are different from the essential therapeutically active constituents. It is therefore important to describe as precisely as possible the penicillin samples used in the experiments. There is some confusion in the penicillin literature owing to the various descriptions of materials used in laboratory and clinical investigations, descriptions that include such terms as “crystalline,” “pure,” “purified,” “crude,” “yellow,” “white.” It has been thought best to follow as closely as circumstances permit the description accepted in this country for the purposes of the Therapeutic Substances Act.

Two preparations were used, differing in “purity.” The first was “penicillin sodium salt,” containing not less than 80% of penicillin G (penicillin II, benzyl penicillin); the other 20% presumably consisted partly of penicillin and partly of material devoid of penicillin activity. It varied in colour from yellow to almost white, according as the impurities contained more or less of pigmented substance derived from the mould. The other material used was “crystalline penicillin G sodium salt”: it contained at least 95% of penicillin G and was a white macro-crystalline product.

For brevity the first type of product is referred to as IP and the second as CPG. The activities in international units were in conformity with accepted standards: the IP batches all had about 1,200 units per mg., the CPG 1,600 or over.

The mice used in the experiments were albinos of both sexes from an inbred colony derived from ancestors of the Strong A2 line. They weighed from 18 to 20 g. at the time of test. Rabbits, of no special strain, were used at body weights of 2.5 to 3 kg.; they received intramuscular injections of 10,000 units of penicillin.

Methods of Infection.—The procedure, including the method of infection, was similar to that of Welch *et al.* (1947), but differed from that of Hobby *et al.* (1947). Two different pathogens were used. A virulent strain of *Bact. typhosum*, having for our mice an LD50 of about 40,000,000 organisms, was injected, at ten times the LD50 of a 24-hour culture, by the intraperitoneal route. The other strain used was *β-Streptococcus haemolyticus* at ten times the LD50 of a 24-hour culture (blood agar), also intraperitoneally. Penicillin injections were given intraperitoneally in the morning followed two hours later by the bacterial suspension. Treatment was given twice daily for four days and the number of mice surviving after seven days was recorded.

Inactivation.—For control purposes all IP or CPG solutions were inactivated with a penicillinase preparation from *Bacillus subtilis* (Ungar, 1944) and then heated at 80° C. for 30 minutes.

Comparison of IP and CPG

Table I gives the results of some comparisons of the two types of penicillin preparation with both kinds of infection. IP (K283) was a fairly old batch of material. The CPG was material from current production. In the experiment recorded in Table I, moreover, the batches CPG 5015 and CPG 5207 consisted of high-potency material made from a part of the same metabolism fluids that yielded, respectively, batches IP 5015 and IP 5207 of less-purified product. Thus the latter may be regarded as consisting of the former together with the natural impurities. A number of experiments like the one summarized here but not involving the use of similarly comparable batches of IP and CPG) were carried out during a period of some 12 months with 18 other production batches of penicillin IP.

TABLE I

Substance	Penicillin Dose (i.u.)	Infection	No. of Animals Used	No. of Survivors
CPG	10	Streptococcus	36	24
CPG + IP K283 inactivated	10	"	36	27
CPG	100	Bact. typhosum	36	5
CPG + IP K283 inactivated	100	"	36	15
CPG	50	"	12	0
CPG + inactivated IP 5015	50	"	12	2
P 5015 + inactivated CPG 5015	50	"	12	2
P 5207 + " CPG 5207	50	"	12	2
P 5015	100	"	24	12
"	450	"	24	23
CPG 5015	100	"	24	8
"	450	"	24	19
Control	—	"	12	0

From these experiments it would appear that mice treated with IP are sometimes better protected than mice treated with the same dose of CPG. The difference between their action in mice infected with streptococcus was not significant; indeed, in some tests mice treated with CPG showed a slightly higher survival rate than mice treated with IP. But our experiments confirmed the superior effect of IP in preventing *Bact. typhosum* infection of mice.

Blood Levels in Rabbits

The next series of experiments was designed to find out whether the estimation of blood levels of penicillin in rabbits after injection of IP would give an indication of the presence of the enhancement factor, as had been suggested by Welch (1947). Blood levels were estimated at 15-minute intervals for the first hour and then half-hourly. The rate of urinary excretion of penicillin was also estimated, to determine whether the less-pure penicillin had the effect of decreasing urinary excretion, as this might partly explain any higher penicillin blood levels.

All the penicillin samples which showed an enhanced activity in typhoid-infected mice were tested, as well as ordinary routine batches.

For each batch a group of four rabbits was used. The tests showed that the type of penicillin tested had no bearing on the levels of penicillin in the blood. Maximum levels were reached after 30–45 minutes; the levels began to fall after 60 minutes, reaching zero after three to four hours, irrespective of the kind of penicillin injected. It was found, however, that the levels of penicillin in the blood differed in individual rabbits, sometimes very considerably. This was apparent in two experiments in which groups of four rabbits were alternately injected with the same two batches of CPG and IP. On the first occasion the batch of IP gave higher blood levels in three of the four rabbits after 60 minutes than did the CPG. In the

second test the first group of rabbits were injected with CPG and gave higher blood levels than the other group now injected with IP. The blood levels clearly depend to a large extent on the individual rabbits. This observation is already well known not only to laboratory workers but also to clinicians, who often record a wide range of penicillin blood levels in patients receiving the same dose of penicillin.

The amount of penicillin excreted in the urine of the rabbits was estimated during the day on catheter specimens and at night on samples collected in metabolism cages. The rate of excretion of penicillin in the urine and the amount of penicillin excreted over 24 hours did not show any difference with the two types of penicillin; with either, between 40 and 90% was accounted for in the urine after 24 hours.

Effect on General Resistance

As the increased effect of IP in our material could be demonstrated with *Bact. typhosum* infection but not with streptococcus, it seemed possible that if the blood levels of penicillin in mice behave similarly to those in rabbits we were here concerned less with the bacteriostatic action of penicillin, which should be "enhanced" similarly against both types of infection, than with an effect on the host, whose neutralization of bacterial endotoxin is being stimulated by the IP. This notion is supported by the fact that the enhancement effect can be shown if the mice are pre-treated with IP; the optimal response occurs if the IP or the impurities present in IP plus CPG are injected into the peritoneal cavity before an injection of the infecting organism. In this event the impurities would be producing just the opposite effect to that of an intraperitoneal injection of mucin-coated bacteria, which enables micro-organisms of low pathogenicity (mainly endotoxin-containing bacteria) to cause a fatal infection in otherwise resistant animals (Miller, 1933). It is appropriate to mention that this effect of mucin is due to several factors, such as the inhibition of phagocytosis and an increased permeability of the barrier between the abdominal cavity and the blood stream (Olitzki, 1948).

To demonstrate, therefore, that the effect of the impurities is on the host rather than directly on the bacteria, we made a few experiments to compare any stimulating effect of the IP with that of colloidal substances known to have such an effect. For this purpose calcium oleate (a suspension of 0.75% calcium oleate in 0.5% gelatin) was used, and the experiments were performed on similar lines to those with IP and mice infected with *Bact. typhosum*. The mice were injected intraperitoneally in the morning with 0.05 ml. of calcium oleate and infected two hours later. The results are shown in Table II.

TABLE II

Substance	Dose in Units	No. of Mice Surviving out of 12
CPG + inactivated IP	100	9
CPG + CPG	100	5
CPG + calcium oleate	100	12
IP	100	8
CPG	100	4
Calcium oleate	—	2
Control mice	—	0

Although the number of mice in each group was not large the results point to a positive enhancement effect of IP, whether inactivated or not, as well as of calcium oleate. The differences between the number of animals protected by CPG alone (4) and by CPG with inactivated IP (9) or with calcium oleate (12) are statistically significant at the 5% level.

Effect of Different Injection Routes

The method of treatment was next altered. One group of mice was treated intraperitoneally with CPG along with inactivated IP or calcium oleate. A second group was treated with CPG intraperitoneally and inactivated IP or calcium oleate subcutaneously. A third group was treated with inactivated IP or calcium oleate intraperitoneally and CPG subcutaneously (see Table III).

TABLE III.—50 Units of Penicillin Into Each of 12 Animals

Substance	Route of Administration	No. of Mice Surviving			
		A	B	C	Total
CPG + inactivated IP ..	Intraperitoneal	7	6	6	19
CPG + calcium oleate ..	"	6	6	5	17
CPG	"	11	10	6	27
Calcium oleate	Subcutaneous				
CPG	Intraperitoneal	10	10	6	26
Inactivated IP	Subcutaneous				
CPG	"	4	3	4	11
Calcium oleate	Intraperitoneal				
CPG	Subcutaneous	2	3	3	8
Inactivated IP	Intraperitoneal				
CPG	"	4	—	—	4
IP	"	8	—	—	8
Control	—	0	—	—	0

A, B, and C indicate contemporaneous tests.

Intraperitoneal injection of double doses (100 i.u.) of IP or CPG, each into 12 mice, produced about 50% protection; 12 unprotected negative controls all died.

From these experiments it seems justifiable to conclude that the simultaneous intraperitoneal injection of CPG and IP, or of CPG and the colloidal suspension, raises the survival rate of the infected mice above that of mice treated with CPG alone at the same dose level. It seems also that the subcutaneous injection of IP (or of the colloidal suspension) increases the effect of intraperitoneally injected penicillin above that produced by the IP and the penicillin injected at the same time by the intraperitoneal route.

Other Colloidal Agents

We also performed an experiment in which other colloidal suspensions, such as colloidal gold or copper (Crookes's "collosol"), were used in place of colloidal calcium oleate or IP. Sixteen hours before infection 60 mice were treated with 0.05 ml. of the colloidal suspension subcutaneously and 200 units of CPG intraperitoneally. Infection with *Bact. typhosum* by the intraperitoneal route followed, and treatment with the colloidal suspension subcutaneously and the penicillin intraperitoneally was given twice daily for four days. In this experiment, therefore, the period of pre-treatment was prolonged to 16 hours, and the treatment itself began about two hours after the infection.

The results after seven days showed that about 30% of the mice survived if pre-treated with the colloidal suspension or IP, but none survived if the colloidal suspension was given two hours after the infection. An injection of IP had an effect similar to that of pre-treatment with the colloidal suspensions, whereas CPG at the same dose as the IP protected only about 10% of the mice.

Leucocytosis in Peritoneal Fluid

The enhancing action of IP on CPG in the previous experiments can be partly explained by the results of the following investigation.

In the preliminary experiment with mice it was found that the normal amount of free peritoneal fluid was very small and that it varied considerably from mouse to mouse. It was therefore impossible to make even an approximate estimation of the leucocyte count in the peritoneal fluid. We therefore injected into the peritoneal cavities of mice

2 ml. of normal saline, killed the mice 40 minutes later, and estimated the number of leucocytes in the peritoneal fluid by the routine method of white-cell estimation in the blood, using 1% acetic acid as the diluent. The number of leucocytes found was about 900–1,200 per c.mm. of the diluted peritoneal fluid, or a total leucocyte count in the peritoneal fluid of about 1.8–2.5 millions, assuming that the leucocytes were evenly distributed.

Having established the normal leucocyte count, we investigated the effect of intraperitoneal injections of calcium oleate, IP, and CPG on it. Groups of three mice were injected intraperitoneally with 2 ml. of saline containing one of the three substances. One hour later the mice were killed, the peritoneal fluid was removed, and the leucocyte count was estimated, with the results shown in Table IV.

TABLE IV

Substance	Amount	Mean Value of Leucocytes (3 mice)
IP	200 units	2,300/c.mm.
IP inactivated	200 "	1,860/c.mm.
CPG	200 "	1,200/c.mm.
CPG inactivated	200 "	1,260/c.mm.
Calcium oleate	0.05 ml.	1,430/c.mm.
Saline control	2 ml.	960/c.mm.

In a second experiment, in which groups of six mice were used, the leucocyte counts in the peritoneal cavities were estimated over a period of three hours after the intraperitoneal injection of IP and CPG, with the results shown in Table V.

TABLE V

Substance	Amount	Mean Value of Leucocytes (6 mice)	
		After 1 Hour	After 3 Hours
IP	200 units	2,000/c.mm.	9,300/c.mm.
CPG	200 "	1,075/c.mm.	5,400/c.mm.
Saline control	2 ml.	1,066/c.mm.	2,800/c.mm.

From these results the justifiable conclusion seems to be that intraperitoneal injection of IP causes a pronounced local leucocytosis in the peritoneal cavity. This leucocytosis probably results in an increased phagocytosis of the bacteria subsequently injected into the same cavity. This stimulated phagocytosis may be one of the factors contributing to the "enhancement effect" of IP.

Discussion

These experiments indicate that IP has a greater protective effect than CPG on mice infected with *Bact. typhosum*. This increase in activity was about 20–40—i.e., 70 units of IP have the same effect as 100 units of CPG. These results confirm the reports of Welch *et al.* (1947) and of Hobby *et al.* (1947). In the results of treatment of streptococcal infections, no appreciable difference between our two types of penicillin was recorded. The more pronounced effect of IP in mice infected with *Bact. typhosum* is also consistent with the finding of Miller *et al.* (1948) that IP has a greater neutralizing effect on bacterial endotoxin (from *Salmonella aertrycke*) when injected intraperitoneally. The increased leucocytosis in the peritoneal cavity after injection of IP is probably a contributory factor in suppressing the endotoxin-containing bacteria.

We have also found that the protective action of CPG in infected mice could be increased by simultaneous administration of colloidal suspensions of calcium, copper, or gold. The method of action of the colloidal suspensions in the presence of CPG may be similar to that of the impurities in penicillin—through increased leucocytosis in the peritoneal cavity. This finding indicates that the "enhancement" effect of the impurities in IP is possibly due to activation of certain defence mechanisms in the

most rather than to any direct action of the impurities on penicillin itself. This would explain why the enhancement effect cannot be demonstrated *in vitro*, and rules out any direct synergistic effect of the impurities on penicillin. We were not able to confirm that the enhancement effect of the impurities caused the higher penicillin blood levels reported by Welch (1947). -

There are as yet no reliable clinical data to demonstrate that less-pure penicillin (from modern deep culture production) has any therapeutic advantages over pure products. Early favourable reports are based on observations with batches of uncertain penicillin content used in the treatment of venereal diseases, mainly gonorrhoea, which are known to respond even to small doses of penicillin. From the pharmacological point of view all the arguments are in favour of using the purest penicillin. It is better tolerated in high doses by sensitive tissues like those of the central nervous system and eye than are cruder products; it has less often been reported to produce allergic sensitization; and it is more stable.

Summary

It has been found that highly purified samples of penicillin G sodium salt were not so effective as less-purified material in protecting mice against infection with *Bact. typhosum*, but that the difference was not demonstrable with streptococcal infections. A suggestion is advanced that the enhancing effect of "crude" penicillin may be partly due to increased leucocytosis in the peritoneal cavity after injection of the impurities present, and it has been shown that certain colloids do produce this leucocytosis and the "enhancement" of purified penicillin.

3. Malignant disease when hepatic metastases are suspected.
4. Hepatic disease in which precise diagnosis is otherwise difficult: fatty infiltration, acute, subacute, and chronic hepatitis.
5. Obscure disorders possibly due to systemic diseases accompanied by morbid changes in the liver, when other methods of diagnosis have proved inconclusive: sarcoidosis, amyloidosis, haemochromatosis, Gaucher's disease, abdominal reticuloses, aleukaemic lymphatic leukaemia, glandular fever, kala-azar, and schistosomiasis.
6. Portal hypertension—to determine whether the obstruction is intrahepatic and whether lipotropic therapy is required before operation.
7. Constrictive pericarditis—to determine the extent of hepatic damage before operation.
8. The treatment of patients with fatty infiltration, smouldering infective hepatitis, or insulin-resistant diabetes.

The contraindications may be listed as follows:

1. Haemorrhagic states, failing to respond to therapy.
2. Marked anaemia.
3. Absence of superficial liver dullness.
4. Senility.
5. Lack of co-operation of the patient.
6. Refusal of the patient to enter hospital. Watson (1948) reports that some persons are carrying out liver biopsy as an ambulatory procedure.
7. The suspicion of liver abscess, hydatid disease, or active cholangitis.
8. Absence of specific indication.

Mortality

There is a widespread opinion that liver biopsy is too hazardous to be adopted as a standard investigation, but this seems to be based upon mortality figures which include series before the discovery of vitamin K. The following are the death rates recorded in modern series:

	Deaths	Biopsies
Gillman (1948)	1	1,000
Sherlock (McMichael, 1948)	2	400
Roholm, Krarup, and Iversen (1942)	2	297
Volwiler and Jones (1947)	1	278
Beek and Haet (1943)	0	200
Davis, Scott, and Lund (1946)	0	79
Herrera and Pardo (1947)	0	72
Hoffbauer (1945)	0	65
Baron (1939)	1	48
Beierwaltes and Mallory (1946)	0	30
Total	7 (0.28%)	in 2,469

This mortality should be assessed in relation to the many accurate diagnoses obtained, but for a fuller appreciation it is necessary to examine the individual deaths.

Gillman's patient bled from an aberrant superficial artery in a "huge tuberculous liver," and that author considered that the patient could have been saved if surgery had been available. Both Sherlock's patients died from haemorrhage and had such severe liver damage that puncture only precipitated the inevitably fatal issue. One had acute necrosis, and the other subacute necrosis, general paralysis of the insane, and rectal carcinoma (Dible, McMichael, and Sherlock, 1943). The two patients of Roholm *et al.* (1942) died from haemorrhage, and although a haemorrhagic state existed vitamin K was not given. One had obstructive jaundice due to carcinoma of the head of the pancreas, and the other glandular metastases in the portal fissure. Volwiler and Jones's fatality followed puncture of the right main hepatic vein 4.5 cm. from the surface of a friable amyloid liver; intrahepatic bleeding led to gross splitting of the liver. Baron's patient had metastases in the liver and elsewhere and bled from a tear 1 cm. long; the bleeding and clotting times were not estimated.

Thus these seven deaths occurred where the prognosis was already hopeless, and three might have been avoided had the haemorrhagic state been treated.

NEEDLE BIOPSY OF THE LIVER

WITH SPECIAL REFERENCE TO A MODIFIED GILLMAN TECHNIQUE

BY

RICHARD TERRY, M.D., M.R.C.P.

Medical Chief Assistant, St. Bartholomew's Hospital

In 1833, at St. Bartholomew's Hospital, Stanley punctured the liver in a case of suppurative hydatid disease. Ehrlich (Frerichs, 1884) obtained liver tissue by aspiration through a needle in research on diabetes, and Lucatello (1895) used a similar procedure for diagnosis. These early reports were followed by studies employing variations of the aspiration technique, but they were largely unsatisfactory. The present status of liver biopsy dates from the work of Iversen and Roholm (1939), and since then its value has become widely recognized.

Indications and Contraindications

The following circumstances have been judged to indicate the use of liver biopsy:

1. Jaundice.
2. Hepatic enlargement of unknown cause.

There have been other deaths, but they have been omitted in arriving at the percentage of 0.28%, either because they occurred prior to knowledge of vitamin K, as the two deaths in 100 biopsies by Bingel (1923) and the two deaths in 160 biopsies by Olivet (1926), or because they have been reported without reference to total biopsies.

Bingel's two deaths were from haemorrhage. One patient had carcinoma of the stomach with hepatic metastases, and the other pernicious anaemia with only 500,000 erythrocytes per c.mm. In neither was the haemorrhagic state investigated. Olivet's two patients died from haemorrhage: one had extensive liver metastases and the other pernicious anaemia with haemoglobin 15%, and again no examination was made of the haemorrhagic state.

Raby (1944) reported one death from puncture of a superficial branch of the portal vein in a woman aged 79 years with jaundice of obscure origin: 1.5 litres of blood were found in the peritoneal cavity; the clotting time was normal. He had a second death three days after biopsy of a man aged 85 years, at whose necropsy no cause of death was found. He felt that the age of these two patients was of some importance. Hoffbauer (1947) quotes an unreported death due to perforation of the colon: the subcostal approach was used although the liver was of normal size.

Thus since 1939 only three deaths have been reported in patients whose prognosis was not already hopeless: of these, two were in patients aged 79 and 85 years, and the third was associated with questionable technique. However, in spite of these reassuring findings, it is necessary to realize that these figures have been obtained by skilled operators constantly using the procedure and that the casual employment of liver biopsy must lead to disasters.

Choice of Method

Iversen and Roholm (1939) used a trocar and cannula 17 cm. long with 2 mm. bore, ending in three sharp points, with a syringe to aspirate the liver tissue. Their method entailed insertion of trocar and cannula into the liver, removal of trocar, further insertion of cannula, attachment of syringe to cannula, withdrawal of syringe plunger, and finally removal of syringe and cannula. These six manipulations required the presence of the cannula within the substance of the liver for 10-15 seconds, during which the patient had to hold his breath. The syringe and cannula occasionally became disconnected at critical moments and the liver tissue, being sucked into the syringe, often broke up. Sherlock (1945) used a similar instrument, but changed to a smaller bore after 126 biopsies with two deaths.

In the U.S.A. the instruments described by Roth and Turkel (1944) and by Silverman (1938) have been preferred. In the Roth-Turkel method a short trocar and cannula are introduced about 1 cm. into the liver, the trocar is removed, and the tissue is punched out by a second longer cannula passed through the first; finally, suction is applied with a syringe. Adapted to liver biopsy by Tripoli and Fader (1941), the Silverman needle differs from the Roth-Turkel in that the longer cannula is split longitudinally and both halves tend to spring apart. Having punched out the tissue with the split cannula passed through the short cannula, the latter is advanced until both tips are level, and then both are withdrawn together, no suction being necessary. These methods have the disadvantages of undue time spent within the liver, frequent failure, and, except for the Silverman method, fragmentation of the specimen.

Watson (quoted by Greene, 1944) failed to obtain tissue for examination in 40%, Iversen and Roholm (1939) in 22.5%, and Hoffbauer (1947) in 23% of his first 65 attempts. The problem of failure has usually been approached by modifying the end of the cannula; the cannula of Franseen (1941) merely had three sharp teeth instead of the three sharp points of the Iversen-Roholm needle. Herrera and Pardo (1947) describe an ingenious arrangement of thread which cuts through the core at its base.

The instrument evolved by Gillman and Gillman (1945) overcame these various defects, having only 5% of failures. The following report is based upon a modification of their instrument and technique: 72 biopsies have been carried out without complication, and failure has been experienced on six occasions.

Description of Modified Gillman Instrument

The instrument is a needle mounted upon a 20-ml. syringe with a stylet fitted to the plunger (Fig. 1). The incorporation of syringe, needle, and stylet in one instru-

FIG. 1.—The liver biopsy instrument

FIG. 2.—Showing details of construction

ment allows all the manipulations of the Iversen-Roholm method to be carried out in a single brief movement. Fig. 2 gives details of construction. A 2-mm.-bore needle is used as a routine, but when there is any likelihood of undue bleeding one of 1.8-mm. bore is substituted. The needle has a bevelled point which produces a linear incision in the liver capsule, whereas blunt-ended cannulae make a round hole. The whole circumference of the end of the needle is internally bored to give a knife edge. An adjustable depth guard is mounted on the needle. The stylet has a flattened side allowing pressures within the syringe to be transmitted to the needle. The spring catch fitted on the syringe cap engages notches on the plunger rod and maintains the plunger in position after suction is applied. These notches are placed at intervals of 1 cm. and permit variation in length of the liver core.

Method

Since the patient's co-operation is essential, a preliminary visit is made to gain his confidence, and the operation referred to in vague terms. No biopsy is done in the presence of increased prothrombin, bleeding, or clotting times. Vitamin K is given as a routine on the two days preceding biopsy and longer if necessary; with jaundic menaphthone 20 mg. is given intravenously, and witho-

adice 10 mg. t.d.s. by mouth. Two pints (1.14 litres) of blood are held available. Morphine, $\frac{1}{2}$ gr. (11 mg.) subcutaneously, is given 30 minutes beforehand and, if the patient is unduly nervous, phenobarbitone 1 gr. (65 mg.) and as previously.

The biopsy is carried out in the ward. The patient lies prone with his right side close to the edge of the bed and his right hand behind his head. The superficial liver dullness is mapped out and a point selected one space below the upper level, usually the seventh intercostal space, in the anterior axillary line. This point is marked by pressure with the fingernail, and the area is swabbed with ether.

A 10-ml. syringe is used to introduce 8-10 ml. of 2% cocaine, at first with a No. 20 needle for the skin and then Nos. 14 and 1 for the deeper tissues. Care is taken to ensure infiltration of the diaphragm and liver capsule with the breath held in expiration. The field of operation is screened from the patient's direct view and the skin incised for about $\frac{1}{2}$ in. (0.8 cm.).

The piston is lubricated with sterile liquid paraffin, the instrument assembled, and smooth working confirmed. This interval allows the analgesic to take effect, gives the patient a moment's relaxation during which he can practise holding his breath in expiration, and permits one to see how long the skin incision bleeds.

The right hand grips the syringe barrel and the left steadies the needle. With the bevels of needle and stylet in apposition, the point is introduced through the skin incision and advanced with a rotary movement. A "give" indicates penetration of the intercostal space, and, with the patient holding his breath, the point is advanced until further resistance is felt; the point is then retracted just clear of the liver. This manoeuvre allows one to judge the thickness of the parietes and to adjust the depth guard, and is especially important with ascites.

After further breaths the patient is told, "Breathe in, breathe out, stop breathing." ("Hold your breath" usually reduces a further inspiration.) The biopsy is then carried out. The point is first advanced about 1 cm. into the liver, and then, with the left hand gripping the syringe handle and maintaining its position (and therefore the position of the stylet), the needle is advanced *sharply* into the liver by thrusting the syringe barrel forwards with the right hand. These are precisely opposite movements to those used in aspirating an abscess, when the barrel is held stationary and the plunger withdrawn. The barrel is advanced an average of 3 cm., which determines the depth of penetration into the liver. The left hand moves to the front of the barrel, and the whole syringe is quickly rotated through 360 degrees and immediately withdrawn.

The core is gently extruded into a glass tube 5 cm. long and of 3 mm. bore, and placed in 10% formal-saline. A dry dressing covers the skin incision.

Aftercare.—The patient remains semi-recumbent for six hours and in bed until the next day. Pulse readings are taken every 15 minutes for two hours and hourly for six hours. The general condition is closely watched. A mild analgesic is given one hour afterwards and a hypnotic in the evening.

Comment on Method

The intercostal approach has been adopted because it appears safe and easy provided the superficial liver dullness is carefully recorded. The costo-xiphisternal angle approach of Gillman and Gillman has not been used because most patients dislike punctures near the praecorium, and, while it is clearly a safe method in their hands, the inability to map out the liver in this area lessens one's confidence. Gillman and Gillman have expressed their fear that the intercostal route might lead to haemorrhage from

diaphragmatic vessels, but if the core is punched out beyond the liver capsule this risk must be small. Davis *et al.* (1946) advise the subcostal approach because of the danger of tearing the liver should the patient breathe with a needle fixed in an intercostal space, but the abdominal wall appears to grip the needle enough to tear a soft liver, while livers of normal consistency are unlikely to tear. The subcostal route has led most frequently to perforation of hollow viscera; Baron (1939), using this route, has reported a fatality from a tear of Glisson's capsule. The progress of the needle through the rigid resistant intercostal space is more easily judged and controlled than through the soft resilient abdominal wall. There is no need to restrict biopsy to patients with hepatic enlargement when the intercostal route is used.

The procedure should be painless. With imperfect analgesia, pain radiates to the right shoulder and epigastrium. General anaesthesia was employed only once, and it proved impossible to assess the patient's condition afterwards. The skin incision eases introduction of the cannula, avoids confusing the pathologist with skin fragments, and allows recognition of any bleeding state.

Failure may occur either because the core remains attached at its base or because the needle passes between the liver cells without punching out a core. Experiments on cadavers, passing the needle through the entire thickness of the lower part of the liver to eliminate the former possibility, demonstrated that failure always followed a slow passage of the needle, but when it was introduced rapidly a core was always obtained. Thus success depends upon thrusting the needle into the liver sharply, and it is useless to proceed unless the instrument is working smoothly. The cutting edge of the needle must be kept sharp. Removal of the core from the deeper part of the liver avoids leaving a bleeding gap in the capsule or cutting a hole in the diaphragm, and rules out misleading subcapsular histology.

Gillman and Gillman advise full withdrawal of the plunger after the needle has been advanced. This must stretch and may break the core; it adds a further manipulation and has not been found necessary. Nor has their method been followed of rotating the barrel on the plunger, rather than the whole syringe, through 360 degrees, as the rotation is more quickly achieved with both hands on the barrel. Since the stylet remains within the needle the core is not sucked into the syringe and so escapes damage.

The time spent by the cannula within the liver is seldom mentioned in the literature, but Volwiler and Jones (1947) recommend aiming at less than 10 seconds. Gillman and Gillman give 15 seconds, but this includes penetration of the abdominal wall. Stopwatch timing of the present method has given times of 1.5 to 3.5 seconds within the liver.

Difficulties.—Women are more apprehensive than men, and present extra difficulty owing to their deeper subcutaneous tissue and the frequent need to retract the right breast. Cirrhosis has special problems. A shrunken liver may be difficult to locate. Distortion may swing the gall-bladder into a vulnerable position. Fibrosis is the cause of many failures and ascites is a well-recognized obstacle, but they have not caused failure in the present series. Finally, the histology of the core may be normal in the presence of gross cirrhosis, a limitation to which Himsworth (1947) and Learmonth (1947) have drawn attention. The six failures in the present series were attributed to instrumental problems in four cases and inexperience in two; in all six patients the biopsy was successfully repeated.

Inspection of the Core.—The small glass tube protects the core, keeps it straight, and facilitates naked-eye

examination. In the present series the core from each case of obstructive jaundice has shown easily visible green spots scattered throughout, while in each case of parenchymatous jaundice the core has been uniformly coloured. Fragmentation of the specimen is suggestive of cirrhosis and has been observed where the histological report was normal, gross cirrhosis being found at operation for porto-caval anastomosis. Metastases show as pale homogeneous areas, and are found more often than might be expected; foci of lymphadenoma have the same appearance. The greasy appearance stated to characterize fatty livers has not yet been observed. Apart from these conditions, considerable variation in the appearance of the core is compatible with normal histology.

Sequelae

There is often slight aching in the right hypochondrium, and occasionally pain in the right shoulder. This pain seldom lasts more than 24-36 hours and causes no distress. Of the present 72 biopsies 47 have had this reaction. 21 cases denied any pain. In four there was more severe pain, starting suddenly 1-8 hours after biopsy; but no anxiety was caused, and one patient readily agreed to a further biopsy. No other complications have arisen. Chest radiographs of ten patients have shown neither pleural effusion nor pneumothorax.

Complications reported in the literature are infection, perforation of a hollow viscus, and haemorrhage. Infection has been rare. Perforations of the colon, duodenum, and gall-bladder have been reported, usually without any reaction, though non-fatal biliary peritonitis and one death from colonic puncture are recorded. Haemorrhage has followed a tear of the capsule or of a superficial hepatic vessel. Haemothorax requiring blood transfusion has been twice noted.

Summary

Some indications for liver biopsy are given.

A mortality of 0.28% is presented, occurring in 2,479 biopsies reported since 1939, and the published deaths are examined in detail.

A description is given of a method of liver biopsy which has been employed in 72 biopsies with neither death nor significant complication.

I am indebted to Dr. R. Bodley Scott for his encouragement and ready assistance; to Dr. Geoffrey Bourne and the physicians and surgeons of St Bartholomew's Hospital who have allowed me to carry out needle biopsy on their cases; to Mr. W. J. Ward, curator to St. Bartholomew's Hospital, and Mr. W. T. Harris, of W. H. Bailey and Sons, for their help in producing the biopsy instrument; to the photographic department of St. Bartholomew's Hospital for the illustration; and to the nursing staff of St. Bartholomew's Hospital for their careful reports.

SEVERE RENAL FAILURE AFTER ADMINISTRATION OF APPARENTLY COMPATIBLE BLOOD

BY

A. C. BUCHAN, F.R.C.S.Ed.

Plastic and Jaw Injury Unit, Bangour Hospital, West Lothia

AND

JOHN WALLACE, M.B., Ch.B., B.Sc.

Glasgow and West of Scotland Blood Transfusion Service

The literature on the Rh blood group is vast, but the recent appeal (*British Medical Journal*, 1948, 2, 344) to publish observations on this subject has prompted us to record the case given below.

The development of irregular haemagglutinins after repeated blood transfusions is now well recognized. Calender and Paykoç (1946) reported that, out of 15 Rh-negative patients transfused with Rh-positive blood, only one developed rhesus antibodies, and Gunz (1946) observed that out of 10 Rh-negative patients who received multiple transfusions two were found to have developed antibodies. These observers point out, however, that had the tests for blocking antibodies (Race, 1944; Wiener, 1944) been performed the percentage of sensitized patients might have been higher. This suggestion is confirmed by Diamond (1946), who in a series of 2,500 Service men transfused under wartime conditions was able to demonstrate rhesus antibodies in the serum of about 50% of the Rh-negative individuals. Hattersley (1947), in a similar but smaller series, demonstrated rhesus antibodies in 11 (55%) out of 20 Rh-negative cases transfused under Service conditions. In all Hattersley's cases the antibodies were in the "blocking" or "incomplete" form, and direct compatibility tests of the patient's serum against saline-suspended Rh-positive cells would not have shown agglutination. However, in spite of this apparent compatibility the transfusion of Rh-positive blood to such a patient would result in a haemolytic reaction. It is for this reason that the following case is presented.

Case Report

A corporal aged 24 received a severe facio-maxillary injury on Jan 1, 1945. At that time he was given 5 pints (2.84 litres) of Group O blood in the course of 36 hours. His Service records make no mention of any reaction to these transfusions.

On July 24, 1946, a bone-graft operation was performed by Mr. A. B. Wallace. During the operation the patient's condition deteriorated, but a satisfactory rise in blood pressure followed the transfusion of 2 pints (1.14 litres) of Group O blood which appeared compatible on direct matching with the patient's serum.

On the morning of July 25 his condition was poor, his pulse rapid and of small volume, and his blood pressure 88/50. His collapse was attributed at the time to post-operative shock. One pint (570 ml.) of plasma and 1 pint of blood were given, and within four hours his general condition had improved, the blood pressure being 106/68. This latter blood was Group O, and appeared compatible with the patient's serum.

On the 27th he complained of nausea and vomiting, and his urine was blood-red in colour. The microscopical report

on the urine was: "Vast numbers of red blood cells and a few pus cells." The urinary output was 560 ml. in 24 hours.

By the morning of the 29th the urine was clear to the naked eye, but the microscopical report stated that a few red cells were present. The nausea and vomiting were more severe. Next day his general condition had deteriorated. Investigation of the blood chemistry gave the following results: urea, 340 mg. per 100 ml.; chlorides, 491 mg. per 100 ml.; uric acid, 4.1 mg. per 100 ml.; plasma albumin, 3.6 g. per 100 ml.; plasma globulin, 1.9 g. per 100 ml. Analysis of the urine showed: chlorides, 0.1 g. per 100 ml.; urea, 1.3 g. per 100 ml.; urinary output, 660 ml. in 24 hours. Because of the increasing vomiting a slow glucose-saline infusion was started on July 30.

The patient remained in a state of uraemia until Aug. 4, when a diuresis occurred, 5.25 litres being excreted in 24 hours. The specific gravity of the urine, which had remained constant at 1010 since the operation, now began to vary, thereby showing the return of the kidney's concentrating power. From this time the blood chemistry revealed a gradual return to normal. On Aug. 10 analyses showed: urea, 55 mg. per 100 ml.; uric acid, 4 mg. per 100 ml. The blood pressure on July 30 was 154/96 and on Aug. 3 it rose to 206/120.

Convalescence was slow. Renal function was investigated by the water concentration, the urea range, and urea-excretion tests in October, and all showed a normal degree of kidney function. Blood pressure was then 128/70.

Special Investigations.—Not until six weeks after the transfusions had been given were these performed, so a complete investigation was not possible. The results were: patient's blood group, O, Rh-negative (genotype rr); patient's serum contained anti-A agglutinin, titre 1/32, anti-B agglutinin, titre 1/16, and incomplete anti-D agglutinin, titre 1/8.

Compatibility Tests.—The routine test of the patient's serum against twelve random Group O cells suspended in physiological saline showed no agglutination. However, when the red-cell suspensions were prepared with AB serum instead of saline there was agglutination of the Rh-positive but not of the Rh-negative cells. Although no agglutination of the Rh-positive cells occurred in the saline suspension, these cells showed that they had been sensitized by a rhesus antibody when tested by the indirect anti-human globulin reaction (Coombs *et al.*, 1945).

In the accompanying Table the total fluid intake, urinary output, daily urinary excretion of sodium chloride and urea, and the level of the blood urea are shown.

Table Showing Urinalysis

Day after Transfusion	Total Fluid Intake (ml.)	Urinary Output (ml.)	Total Daily Urinary Excretion		Blood Urea (mg. per 100 ml.)
			Chloride (g.)	Urea (g.)	
1st ..	—	—	—	—	—
2nd ..	—	150	—	—	—
3rd ..	—	560	—	—	—
4th ..	2,490	600	—	—	—
5th ..	2,190	630	0.6	8.1	—
6th ..	2,180	660	0.7	8.6	340
7th ..	2,580	1,080	1.1	14.4	320
8th ..	2,730	1,380	3.5	18.4	340
9th ..	3,090	1,920	4.9	25.5	340
10th ..	4,050	2,970	9.9	39.6	340
11th ..	5,100	3,000	9.0	42.0	325
12th ..	4,740	5,250	6.8	73.5	270
13th ..	4,860	5,190	—	78.0	230
14th ..	5,010	4,800	6.2	92.0	210
15th ..	4,470	4,740	5.2	74.2	150
16th ..	3,840	3,870	—	—	—
17th ..	3,870	3,480	—	—	—
18th ..	4,080	3,390	4.1	66.0	55
19th ..	2,850	2,790	—	—	—

Before the onset of a copious diuresis on the twelfth day there had been a gradual daily increment in the 24-hour urinary output. For a few days after the onset of the diuresis the urinary output was greater than the total fluid intake. Muirhead *et al.* (1948) found that with the onset of diuresis not only was the water excretion markedly raised but the daily urinary excretion of sodium chloride was greatly increased. These workers suggested that the renal tubules had recovered sufficiently to allow for urine volume production, but that the recovery was not yet advanced enough to allow for the

conservation of water and salts. In the present case there was a marked increase in the daily excretion of urea, but the excretion of sodium chloride, while increased, remained within normal limits. It would seem that the kidney had recovered sufficiently to conserve sodium chloride. It has been emphasized (Muirhead *et al.*, 1948) that with the onset of the diuresis the kidneys may discard water and salts to the extent of causing pronounced dehydration or even death. It is therefore essential in the treatment of this phase to replace the water and salt lost from the body.

Discussion

The differential diagnoses considered at the time of the reaction were: (1) *Haemolytic transfusion reaction*:—This was considered unlikely on account of the careful compatibility tests made in the hospital laboratory and in the absence of the classical features, such as rigor, pain in the back, fever, or jaundice. There was no question of the blood having been overheated or being haemolysed by faulty or prolonged storage. (2) *Sulphonamide haematuria* can be excluded, as the patient was receiving penicillin but no sulphonamide drugs. (3) *Acute nephritis*:—This appeared the most likely diagnosis in view of the picture of uraemia associated with oliguria, red cells in the urine, and hypertension. Against such a diagnosis, however, was the absence of any recent infection, the absence of casts, and the low specific gravity of the urine.

As a haemolytic transfusion reaction was considered unlikely at the time, no special investigations were undertaken in the hospital, apart from checking on the ABO grouping of the patient and the donors and repeating the compatibility tests. These routine tests were satisfactory.

At the time of the special investigations six weeks later it was confirmed that the findings in the hospital laboratory were substantially correct, but the additional investigations revealed that the patient was Rh-negative and had "incomplete" rhesus antibodies in his serum. The development of these antibodies probably followed the original transfusion at the time of wounding in 1945. The transfusion of Rh-positive blood to an Rh-negative patient with "blocking" antibodies would then result in a haemolytic reaction, and it is believed that this is the explanation of the severe renal failure which developed.

There are several points about this particular case which seem worthy of mention.

1. Absence of the Classical Features of a Haemolytic Reaction

The absence of such reactions as tingling sensations of the skin, tightness in the chest, severe backache, dyspnoea, and cyanosis may be explained by the fact that the patient was anaesthetized during the transfusion of the first two bottles of blood. On the other hand, Mollison (1943) mentioned that reactions to incompatible transfusion seemed to be less severe than formerly, and Drummond (1944) describes a case of symptomless incompatible transfusion.

The presence of vast numbers of red blood cells and a few pus cells in the urine seemed to be in favour of a diagnosis of nephritis rather than of a haemolytic reaction. However, the presence of intact red blood cells in the urine is common, and white blood cells, often in clumps, are present during the oliguric period following an incompatible transfusion (Muirhead *et al.*, 1948). Pigment granules, often about the size and shape of a red blood corpuscle (for which they are not infrequently mistaken), are seen in haemoglobinuria (Bywaters and Dible, 1943).

2. The Severity of Renal Failure

In general, sensitization to the Rh antigen which occurs as a result of repeated transfusions develops slowly and early reactions are mild or inapparent (Mollison, 1948). In this case the reaction was severe after virtually the

second transfusion. The original transfusion of 5 pints of blood within 36 hours at the time of wounding can be regarded as a single antigenic stimulus. It is of comparative interest that Cappell (1948) has found that the first recorded manifestation of haemolytic disease of the newborn due to Rh incompatibility is usually one of the severer forms, contrary to the widely held belief that the first one or two affected children in a family show only mild symptoms.

Unfortunately, the volume of incompatible blood transfused in the case is not known with certainty, but the late Dr. Douglas Macrae, of the Edinburgh Blood Transfusion Service, informed us that at the time of the transfusion it was the practice to screen all Group O donors with a diagnostic anti-D serum, and, as it is certain that blood specifically marked Rh-negative was not given to this patient, the probability is that 1,600 ml. of incompatible Rh-positive blood was given. Bordley (1931) stated that cases receiving larger volumes of incompatible blood tend to be more serious—a conclusion with which Muirhead *et al.* (1948) are in general agreement. On the other hand, one of us (J. W.) has recently seen a Group O patient who had only a transient haemoglobinuria following a transfusion of 4 pints (2.27 litres) of Group A blood and did not develop renal failure. The anti-A titre of this Group O patient's serum four weeks after transfusion was 512,000. The probability is that several factors play a part in producing renal failure in such cases, the most important being renal anoxia (Maegraith *et al.*, 1945).

3. Compatibility Tests

The direct compatibility test in which the patient's serum is set up against saline suspensions of red cells will fail to detect the presence of blocking antibodies. To detect such antibodies the red cells must be suspended in AB plasma or preferably in 20% bovine albumin solution (Mourant, 1948). There is of course no proof that in this case blocking antibodies would have been detected in the patient's serum before transfusion. These antibodies may disappear after the original sensitization, but can be produced again very rapidly following the appropriate antigenic stimulus.

The two most important lessons to be learned from this case are (i) always to determine the Rh blood group of any patient previously transfused, and (ii) the so-called compatibility test is not an absolute safeguard against incompatibility.

4. Survival of the Patient

Many forms of therapy have been advocated in the treatment of haemolytic transfusion reactions—e.g., alkaline therapy, forced fluids, transfusion of compatible blood, splanchnic block, and decapsulation of the kidney (Kilduffe and De Bakey, 1942)—but opinions differ on the value of these methods. Few observers are in a position to study a large controlled series of such cases, and this renders assessment of a particular form of therapy difficult. According to De Gowin (1938) some patients recover spontaneously, while others die in spite of the therapeutic measures advocated. The present case illustrates that even severely damaged kidneys may recover completely without any heroic therapy.

Summary

A severe degree of renal failure from which the patient subsequently made a complete recovery occurred after a blood transfusion.

The transfused blood appeared to be compatible when tested against the patient's serum.

On investigation the patient, who had been transfused previously as a war casualty, was found to be Rh-negative and to

have rhesus antibodies of the incomplete, blocking, or albumin-aggutinating variety in his serum.

The importance of determining the Rh group in any patient previously transfused, and the danger of relying on the direct compatibility test only, are stressed.

The clinical features and treatment of haemolytic transfusion reactions are discussed.

We wish to thank Dr. W. M. McAlister, medical superintendent of Bangour Hospital, for permission to publish this case. We also acknowledge with thanks the help received from Dr. I. A. Purdie in the biochemical investigations and the helpful co-operation of Mr. A. B. Wallace, who was in charge of the case.

DYSENTERY IN SOUTH PERSIA

BY

IAN S. STEWART, M.B., Ch.B.

Pathologist, Anglo-Iranian Oil Company

The control of this group of diseases, apart from the relief of the patients' discomfort, is of importance because they are productive of much time-wastage and inefficiency matters of outstanding interest to a commercial concern. Moreover, the opportunity of identifying and segregating the patients who continue to be infective after apparent recovery will bring about a steady reduction in the incidence of the dysenteries in the province of Khuzistan South Persia.

Accordingly arrangements were made in March, 1947 for all cases regarded as dysenteric, either on clinical grounds or from the initial examination of the stools in the laboratory, and arising among the company's 30,000 male artisan employees on Abadan Island, to be admitted to the Isolation Hospital, a segregated wing of which was allocated for this purpose. The project had been under consideration for two years but had been delayed by the restricted supplies of sulphaguanidine. The arrival of a hundredweight (50 kg.) of this drug in March was followed by the opening of a forty-bed ward on April 1, and the figures subsequently quoted relate to the admissions between April 1, 1947, and April 1, 1948.

The survey relates to a permanent and static civilian population and therefore has a value greater than that of a survey of the same diseases during the conditions of war when large masses of population are moved into abnormal sites and situations. Apart from its local value it has a bearing on the steadily increasing flow of short-term visitors of all nationalities drawn to the Persian Gulf by its

growing commercial importance. A proportion of these visitors will no doubt develop intestinal disturbances after leaving the area, and the rarity of amoebiasis in this particular area, shown in Table I, makes it unlikely that this disease will need serious consideration.

TABLE I.—*Diagnosis*

Amoebic dysentery in which vegetative <i>E. histolytica</i> was the sole agent found	52
Cases failing to respond to sulphaguanidine and in which <i>E. histolytica</i> was found later	2
Cases failing to respond to sulphaguanidine and treated as amoebic dysentery without proof	1
Balantidial dysentery in which <i>Balanidium coli</i> was the sole agent found	13
Pure bacillary infections:	
<i>B. dysenteriae</i> Flexner	353
Schmitz	49
Sonne	97
Shiga	19
Boyd	22
Mixed dysentery:	
<i>E. histolytica</i> and Flexner	3
and Boyd	2
<i>Balanidium coli</i> and Flexner	2
and Sonne	2
Bacillary type cases with negative culture responding to sulphaguanidine	698
Admitted late without laboratory investigation and responding to sulphaguanidine	115
Total	1,430

Table I is devoted solely to the dysenteries, the irrelevant admissions having been excluded. Such diverse conditions as diverticulitis, carcinoma of the colon, constipation, the acute diarrhoea of aestivo-autumnal malaria, and many more have inevitably arrived in the ward from time to time and have been redirected to the appropriate departments.

Proved amoebic dysentery therefore accounted for only 3.8%, whereas proved bacillary infections accounted for 37.3%, and 56.6% were of bacillary type but unproved. Balantidial and mixed dysenteries account for the balance.

The following facts are in favour of the bacillary origin of the cases in which no pathogen was seen or isolated: (1) A clinical side-room with a competent technician has been in existence close to the dysentery ward for four months and all cases slow in responding to sulphaguanidine have been reviewed. In only one case has *Entamoeba histolytica* been found. (2) The frequent use of test purges in these cases without result. (3) The absence of Charcot-Leyden crystals, the mucoid nature of the stools, and the characteristics commonly found microscopically in cases of bacillary dysentery. (4) The headache, the fever, and a colic relieved completely by the passage of a stool.

TABLE II.—*Carriers**

Organism	Carriers	Total Recorded	Percentage of Total
<i>B. dysenteriae</i> Flexner	21	358	5.9
" Sonne	8	99	8.1
" Schmitz	2	49	4.1
" Shiga	1	19	5.3
" Boyd	3	24	12.5
Total	35	549	—

* The medium used was SS ("difo") desoxycholate citrate agar adjusted to pH 7.

Table II resulted from the following procedure: Each case was detained in hospital for two days after sulphaguanidine therapy had ceased, the next stool passed was cultured, and the patient was discharged without waiting for the result. Those cases found to be positive were readmitted and given a course of 100 g. of the drug; all cases were then found to be free of infection. Multiple cultures would no doubt have revealed even more carriers, but the retention of so many recovered patients for six or seven days would not only have given rise to great discontent among the patients but added a further volume of work to the laboratory and put extra pressure on bed accommodation.

Treatment

Amoebic Dysentery.—All cases were given 4 g. of sulphaguanidine four-hourly, including the night hours, to a total of 20 g. Emetine hydrochloride in a dose of 1 gr. (65 mg.) was given daily for ten days and was followed by a five-day course of 0.25 g. of quinoxyl by mouth three times a day, and a retention enema of 5 g. in 200 ml. of saline each evening. Seven of the 54 cases were readmitted with a relapse in the course of the year.

Bacillary Dysentery.—Sulphaguanidine, 4 g. four-hourly, was given day and night until the patients were afebrile and symptomless. Table III shows the quantities required.

TABLE III.—*Sulphaguanidine Dosage*

Group	20 g.	40 g.	60 g.	80 g.	100 g.	120 g.	140 g.	Total
Flexner	116	87	50	58	24	17	1	353
Sonne	43	28	8	16	2	—	—	97
Schmitz	15	17	8	7	2	—	—	49
Shiga	11	5	3	—	—	—	—	19
Boyd	15	5	1	—	—	—	—	22
Clinically bacillary	364	181	98	41	10	4	—	698
No lab. investigation	66	24	14	4	7	—	—	115
Total	630	347	182	127	45	21	1	1,353

Expressed in units of 20 g., the average requirement of each group is as follows: Flexner, 2.5; Sonne, 2; Schmitz, 1.3; Shiga, 1.6; Boyd, 1.7; clinical dysentery, 1.8; no investigation, 1.8.

Complications.—The only major complication worthy of record is acute hepatitis, which may or may not have been amoebic in origin, ten cases developing while in hospital. One of them was admitted with a Sonne infection and one with a Flexner. The remainder had negative stool cultures. In none had amoebae or cysts been seen in the stools, but all responded satisfactorily to emetine.

Mortality.—No death occurred in the series. Two individuals who were not employees died with bacillary dysentery as a terminal event, one being a case of advanced rheumatoid arthritis and the other an old man with prostatic hypertrophy and acute retention.

Summary

An organization for the control of dysentery in a large industrial population is described, the frequency of the different forms assessed, and an analysis made of the quantities of sulphaguanidine required in the different bacillary types.

Acknowledgments are due to Dr. S. D. McClean, chief medical officer, A.I.O.C., for inspiration and advice; to Dr. M. A. Khorram for his co-operation in the conduct of the ward; and to Lieutenant-Colonel H. J. Bensted, director of the Standards Laboratory, for the supply of diagnostic sera.

The Minister of Food has made the Mineral Oil in Food Order, 1949, which came into force on April 9, prohibiting the use of mineral oils in the manufacture of food for sale to the public. The Ministry states that for some time past the Ministries of Food and Health and the Department of Health for Scotland have been concerned both on medical and nutritional grounds about the growing practice of using paraffins in the preparation of food. The Ministry also urges housewives not to use these substances in home cooking. The statement says that deposits of medicinal paraffin would not, so far as is known, be harmful in themselves, but the same could not be said for other mineral oils, many of which are known to contain harmful substances. "Too little is known about the fate of deposits of mineral oils in such organs as the liver for the medical profession to remain indifferent about them." The risks of consuming liquid paraffin were discussed in a leading article in this *Journal* in 1948, June 12 (p. 1141). It concluded with these words: "On the evidence available, therefore, the use even of refined liquid paraffin (B.P.) in the preparation and cooking of food is to be condemned. . . . The internal use of other (unrefined) mineral oils in any shape or form must always be condemned."

FURTHER EXPERIENCES WITH ETHINYL OESTRADIOL IN THE SUPPRESSION OF LACTATION

BY

T. N. A. JEFFCOATE, M.D., F.R.C.S.Ed., F.R.C.O.G.

AND

BETTY HARGREAVES, M.B., Ch.B., M.R.C.O.G.

(From the Department of Obstetrics and Gynaecology, University of Liverpool)

In a previous communication (Jeffcoate *et al.*, 1948) it was mentioned that some writers had suggested that ethinyl oestradiol when administered orally has a more prolonged action than other oestrogens. To test the validity of this suggestion further clinical trials have been carried out, the suppression of lactation again being the test object. The total dose administered was of the same order as in the previous trials, but it was all given in one or two days instead of being spread over seven days. Single doses were impracticable, since it would have meant that a patient took a very large number of 0.05-mg. tablets at one time. In one scheme the total dose was given during one day and usually within twenty-four hours of delivery; in the second the same total dose was given, half during the first day and half during the fourth day of the puerperium. Thirty-seven patients were treated, and the results are classified as excellent, good, fair, or poor, according to the criteria set out previously.

Scheme I

(a) *Technique*.—Eleven tablets (0.55 mg.) during the first day, administered in three doses at four-hourly intervals. *Results*: Six patients were treated, two with excellent results. Two had fullness of the breasts with pain on the fourth and fifth days, one had free secretion of milk on the fourth and fifth days, and a sixth complained of fullness and pain on the sixth day. A supplementary course of treatment with 0.1 mg. of ethinyl oestradiol was necessary in these four cases. (Two excellent, four poor.)

(b) *Technique*.—Fifteen tablets (0.75 mg.) during one day, administered in three doses at four-hourly intervals. *Results*: Seven patients were treated, one with excellent result. Two experienced fullness of the breasts with slight discomfort—on the second day in one case and on the fourth day in the other. In the latter, treatment did not begin until the second day of the puerperium. Four patients showed a poor response. In two of these, symptoms arose on the sixth and seventh days and necessitated further treatment. The two others started treatment on the second day and had pain and fullness on the following day. (One excellent, two fair, four poor.)

(c) *Technique*.—Twenty tablets (1 mg.) during the first day, administered in four doses at four-hourly intervals. *Results*: Four patients were treated, one with excellent result. A second patient had pain and fullness on the fourth day, a third had similar symptoms on the eighth day, whilst a fourth had a free flow of milk from the sixth to twelfth days. (One excellent, three poor.)

Scheme II

(a) *Technique*.—Six tablets (0.3 mg.) first day, five tablets (0.25 mg.) fourth day—total, 11 tablets (0.55 mg.). *Results*: Six patients were treated, three with excellent results and two with good results. Of the latter, one had slight secretion on the fourth and the other on the fifth day. A sixth had minimal discomfort on the second day only. (Three excellent, two good, one fair.)

(b) *Technique*.—Eight tablets (0.4 mg.) first day, seven tablets (0.35 mg.) fourth day—total, 15 tablets (0.75 mg.). *Results*: Seven patients were treated, two with excellent results. Four cases had moderate fullness of the breasts on the fourth day,

relieved by the second dose, whilst the seventh case had fullness and pain on the fourth day. (Two excellent, four fair, one poor.)

(c) *Technique*.—Ten tablets (0.5 mg.) first day, ten tablets (0.5 mg.) fourth day—total, 20 tablets (1 mg.). *Results*: Seven patients were treated, with excellent results in three cases and with a good result in another two. The remaining two cases had pain and fullness of the breasts—one on the fourth and the other on the sixth day. Both required further treatment. (Three excellent, two good, two poor.)

Conclusions

The results of these trials may be summarized by saying that ethinyl oestradiol in relatively large doses given over a short period or at long intervals is unreliable in suppressing lactation, whereas in divided doses spaced over several days it was previously shown to give excellent or good results in a high percentage of cases. With a total dose of 0.55 to 0.75 mg. given during the first seven days of the puerperium an excellent or good response was noted in 24 out of 27 cases in the previous trials. In this series, 0.55 mg. to 1 mg. administered during a period of 12 hours produced only four good or excellent results in 17 cases. When it was divided and given half on the first day and half on the fourth day of the puerperium the effect was satisfactory in 12 out of 20 cases.

The results reported here compare so unfavourably with the earlier ones that it seems permissible to conclude that they offer little evidence to support the idea that ethinyl oestradiol is absorbed or utilized comparatively slowly and that its effect is prolonged. If it has these properties, then they are not so strongly developed as to make the administration of single massive doses, or large doses at infrequent intervals, an efficient method. As in the case of other oestrogens, smaller doses given regularly during several days are the most effective.

METATARSUS QUINTUS VALGUS

BY

HORACE DAVIES, Ch.M., M.Ch.Orth., F.R.C.S.

Orthopaedic Surgeon, St. Catherine's Hospital, Birkenhead, and Whiston Hospital, Lanes

Much individuality appears to exist in the shape of the fifth metatarso-phalangeal junction. Rarely do we see a foot with its outer border prolonged straight forward along the little toe. The head of the metatarsal interrupts this line by protruding outwards, and the axis of the little toe is usually directed inwards. Most feet therefore exhibit a bunionette, or, as it has been called, a tailor's bunion, to a greater or less degree. Rarely, however, does it give rise to symptoms. A bunionette is not uncommonly seen in combination with pes and hallux valgus and general splaying of the forefoot, and is therefore regarded as a secondary deformity in these cases. Chronic irritation due to pressure upon the lateral surface of the foot in the cross-legged or sartorial position is also to be considered as a causative factor, for it was this that gave rise to the name "tailor's bunion." The case of bilateral bunionette described below appeared as a primary and independent deformity, and the suggestion is made that such a condition can occur as a distinct clinical syndrome.

A girl aged 9 came to the clinic complaining of painful swellings at the bases of the little toes. They had been

noticed about two years previously, but had remained symptomless until the last six months. Examination revealed unusually prominent swellings over the fifth metatarsophalangeal joints, with the little toe directed inwards, following the axial deviation of the outer three digits. Radiographs show a varus position of the little toe, adaptive changes in the basal phalangeal and metatarsal epiphyses, and outward splaying of the fifth metatarsal. Clinically and radiologically the condition therefore resembles metatarsus primus varus.

Aetiology

In considering the cause of this condition we must refer to the embryology of the foot. The mesodermal concentrations destined to be the metatarsals are laid down radially, diverging towards the convex border of the limb bud. This fanwise arrangement persists up to about

the 20-mm. stage. At this time we see the differentiation and development of the transverse metatarsal ligament, and his restraining rein thrown across the heads of the developing metatarsals appears to exert a converging influence. Development proceeds with the metatarsals assuming the more parallel positions they occupy in the adult. Imperfect attachment of the transverse metatarsal ligament to the fifth metatarsal could allow primitive divergence to persist, which I would suggest is the primary error in this condition.

In the early stages the developing digits radiate from the convex border of the limb bud, following the lines of the diverging metatarsals, and their realignment to the adult position is difficult to explain. It would appear, however, that two factors are at work: (1) the inherent human pattern responsible for the blue-print of our shape and size, and (2) mechanical forces.

In considering these mechanical forces we see that the changing shape of the developing foot plays an important part. The convex border of the embryonic foot presents at first a large arc of a small circle. As development proceeds this arc expands, gradually transforming itself into a wider arc of a larger circle, with predominant expansion of the pre-axial side. This expansion of the arc brings the radiating toes into more parallel positions. Coinciding with this, the developing intrinsic and extrinsic muscles begin to exert their influence. The flexor longus digitorum, pulling from the inner margin of the foot, has an adducting effect upon the third, fourth, and fifth toes. This pull is

exerted mainly upon the terminal phalanges. The toes are pulled into their parallel positions, but in many individuals this pull continues beyond the normal, and the terminal phalanges are adducted and flexed. The intrinsic muscles, especially the pedal interossei, should prevent this, as one of their little-appreciated functions is to extend the two terminal phalanges. There thus develops a minor tug-of-war between the strong adduction flexing action of the long flexor and the relatively weak degenerating interossei. Now if the primitive divergence of the fifth metatarsal persists the obliquity of the flexor pull is increased and the whole fifth digit becomes adducted.

Treatment.—Rarely do these cases require active treatment other than the provision of well-fitting shoes. Bunionectomy or trimming of the lateral surface of the metatarsal head may be necessary in pronounced cases with clinical symptoms. If the primary factor is the abduction of the metatarsal shaft, osteotomy should theoretically be the treatment of choice, but in practice, as for metatarsus primus varus, this procedure is both unnecessary and often unsatisfactory.

Summary

Unusual prominence at the fifth metatarsophalangeal joint is either a primary or a secondary deformity. If it occurs as an independent condition it constitutes a syndrome, which should be described as metatarsus quintus valgus. The underlying basic congenital error is the persistence of the embryonic splaying of the fifth metatarsal, probably due to incomplete or imperfect development of the transverse metatarsal ligament.

Medical Memoranda

Sprue-like Mouth and Swelling of Lips as a Manifestation of Streptomycin Sensitivity

Many toxic manifestations of streptomycin have been described, but the following experience seems to add one more to the list of "dangers."

CASE HISTORY

A man aged 57, a wine merchant of moderate habits, was recently seen by me for chronic pulmonary tuberculosis. There was infiltration of both lungs, with cavitation on the right, and it appeared from the history and from his subsequent response to conservative treatment that he was going downhill. It was therefore decided to try streptomycin. The streptomycin used was streptomycin calcium chloride complex, and the amount given was 1 g. daily in two doses. One month later the E.S.R. still remained high (95 mm. in one hour), but there was considerable subjective improvement. He, however, complained of some temporary giddiness following injections which did not amount to vertigo.

Five weeks after the beginning of treatment he complained of slight weakness of the legs, particularly noticeable on climbing stairs, and on the same day there was a feeling of numbness of the lips with a slight swelling of the mucous membranes. Within two days the patient complained of a feeling of thickness of the tongue, which subsequently became furred and after a few days ulcerated; at the same time there was some superficial ulceration of the inner aspects of the cheeks, the whole picture resembling severe sprue except that the lips were swollen.

Professor G. Ransome saw him at this stage and suggested that a vitamin-B deficiency factor might be contributory. Sensitivity was suspected in view of the lip-swelling. The streptomycin was stopped and the patient was given daily five 4-ml. injections of "plexan" and an adequate dosage of vitamin-B complex. The condition slowly subsided over a period of three weeks, during which time he experienced considerable pain.

Three weeks after stopping streptomycin it was decided to try a test dose to establish whether or not this was indeed a manifestation of streptomycin sensitivity. Three hours after injection of 0.5 g. the lips and tongue swelled, the pulse rate increased, and the patient felt warm all over and itchy. There was a migraine-like headache. Two mg. of adrenaline in oil was given and 50 mg. of "benadryl" thrice daily, this being continued for a few days. The immediate distress was relieved within a few hours, but the swelling of the lips and

tongue remained for a week. The dorsum of the tongue again ulcerated and took a further fortnight to heal.

It seems clear, therefore, in view of the fact that fungous and bacillary infections were ruled out, that this was a surface necrosis of the mucous membrane of the tongue, cheek, and lips directly due to streptomycin.

L.M.S. Singapore

Death from Lightning-stroke, with Multiple Injuries

Textbooks of forensic medicine are unanimous in stating that lightning-stroke may be accompanied by signs suggestive of great mechanical violence, but in actual practice gross injuries other than burns seem to be comparatively uncommon. Peterson, Haines, and Webster (1923) state that Schneider was among the first to record the fact that bones may be broken and blood vessels ruptured; while Rhodes, Gordon, and Turner (1945) say that the lesions vary in extent and nature and usually

take the forms of burns of different degree, but that deep-tissue destruction with fractures of the bone occurs in certain cases.

Dixon Mann (1922) quotes a case in which there was a compound fracture of the right tibia and a comminuted fracture of the os calcis; there were also extensive burns. He goes on to say that fractures of the bones, including those of the skull, have occurred, but only exceptionally. Lyon (1935), quoting Tidy, states that fractures are rare but have been found in a few cases. Glaister (1945) describes a case of fractured base and in another a compound fracture of the tibia.

Taylor (1948), Sydney Smith (1940), Keith Simpson (1947), and other authorities make similar statements, but I have not been able to find a published case exhibiting the degree of injury shown in the accompanying photograph.

CASE HISTORY

On March 22, 1948, at half-past six in the morning, there was a sudden sharp thunderstorm accompanied by heavy rain. As is common in this part of the world, the electrical manifestations of the storm may be limited to one or two vivid flashes accompanied by heavy crashes of thunder, and in this particular instance the only significant flash was responsible for this one fatality.

I accompanied the police officer to a small native hut in which the occupant had been killed. The hut, consisting of a single room, was constructed of sticks and mud with a low thatched roof. The walls and thatch were dilapidated, but there was little evidence of recent damage. About 9 in. (22.8 cm.) from the rear wall there was a coconut tree, which showed signs of the effects of recent lightning. The top was damaged and at intervals down the trunk the bark had

been torn off. In fact, the tree-trunk had the appearance of having been clawed by a giant animal.

There had been two occupants of the hut—the dead man and his elder brother, the latter sleeping in a bed and the former on a mat adjacent to the wall nearest to the coconut tree, and within a foot of the bed. There was no direct evidence about the patient's position at the time of the fatal flash. The surviving occupant stated that his brother left the hut at daybreak to go to the latrine and returned about two minutes before the flash. The survivor was practically unhurt, but was somewhat dazed and unable to give an account of the accident. He was unaware whether his brother had been standing, sitting, or lying down at the actual moment.

The body was found lying at full length on the remains of the sleeping-mat with the head resting on a folded fez cap. The mat itself appeared to have been blown to pieces: some fragments were found adhering to the under surface of the thatched roof. The body was naked, and it is of some interest to know that it was occupying exactly the same position and adopting the same attitude as would have been the case had death occurred in sleep and if the shock had not disturbed the body to the slightest degree. The surviving brother and other villagers were quite definite that no one had touched the body after death. This is probably true because, besides the native reluctance to touch a body slain in this manner, he would never consider the corpse's comfort to the extent of folding a cap and placing beneath the head. It is suggested therefore, that all the injuries were due solely to the blasting action of the lightning, and it would seem that the man, having returned to his hut, had lain down on his mat again and made himself comfortable pending the coming of the storm.

The injuries are well illustrated in the photograph. On the left side of the neck all the soft tissues between the trachea and cervical vertebrae had been blown out, leaving a gap in which a closed fist could be placed. The wound on the left shoulder involved the whole of the deltoid region and showed a double fracture of the humerus, one at the neck of the bone and the other 4 in. (10 cm.) low down the shaft. The separated portion of bone was lying free in the wound completely denuded of muscle. There were scattered superficial wounds and abrasions of the face and chest, and on the right side of the abdomen a slate-grey in colour, the skin being dead and parchment-like. No actual burning or singeing could be seen. Superficial wounds in the pubic region involved the penis and scrotum, and on the inner sides of both thighs deep lacerated wounds extended from the groins to within 2 in. (5 cm.) of the knees. There was a lacerated wound of the right big toe, with smaller wounds on the dorsum of the foot.

The scalp was uninjured, but a fracture of the left side of the frontal bone proceeded outwards and downwards to the base and a fracture of the right parietal bone passed backwards over the occipital bone to the foramen magnum. The base of the skull was shattered by multiple fractures, with displacement of the fragments. The brain showed no macroscopic signs of injury.

The Ministry of Health and the motor industry have agreed on a scheme for speeding delivery of cars urgently required by domiciliary midwives. A midwife who already has a car must produce evidence that it is not reliable. Local supervising authorities will certify the urgent need for a car. Similar certificates must be obtained from nursing associations or hospitals who have ordered cars for domiciliary midwives. The scheme does not apply to home nurses who do not undertake midwifery or to health visitors.

Reviews

HOSPITAL ADMINISTRATION

A Study of Hospital Administration. Studies in Public Administration. By Frank Hart and A. J. Waldegrave. (Pp. 188. 15s.) London: Stevens and Sons. 1948.

The growth of hospitals in Britain has been extraordinarily aphazard and comparatively unrelated to the overall needs of the local community. Consequently administration throughout the hospital field is very variable, and a complete description of the variations is almost impossible within the limits of a somewhat brief study. However, those interested will find an up-to-date account of methods of administration at the general, voluntary, and local authority hospitals as they existed until July 5, 1948. The efficiency of members of regional boards and hospital management committees would be much increased if each possessed the knowledge contained within these pages; perhaps the Minister of Health may see it to present a copy to each member.

The authors discuss at length the vexed question of lay and medical administration, and the point of view which they express has a slight bias towards a lay head. Unfortunately, though the power of the medical staff is effectively safeguarded, they put forward no practical solution for meeting the medical needs of the local community, particularly in respect of difficult subacute and chronic cases. They emphasize the importance of medical staff committees, but though they give an excellent account of present nursing administration they do not suggest that nursing committees should be established in each hospital with powers equivalent to those held by their medical colleagues. They show that some hospital departments lack up-to-date business methods, particularly in relation to management of the staff and the facilities provided for them. If these defects were remedied, hospitals would not find the same difficulties in recruiting staff as they do to-day.

The chapter on planning gives some pointers to the future and refers the reader to several excellent reports on which such planning should be based. Here the great shortage of beds is emphasized, while elsewhere the authors frankly face the problem of insufficient nurses. This book can be highly recommended for the facts it contains, and we trust these will stimulate those who read to formulate a constructive hospital policy.

HORACE JOULES.

MANUAL OF DISSECTION

Ellis's Anatomy. Being a Manual of Dissection and Textbook of Regional Anatomy. Revised and edited by J. A. Keen, M.B., F.R.C.S. (Pp. 487. Illustrated by 216 of the original engravings, of which 79 are in colour. £2 2s.) Capetown: Stewart Printing Co. (Pty.), Ltd. London: John Murray. 1946.

This ancient manual of dissection by George Viner Ellis (1812-1900) was first published in 1840. Ellis occupied the chair of anatomy at University College from 1850 to 1877. Keen, through some inexplicable lapse, states in the preface to this new edition that "Professor Ellis, the original author of this book, was Emeritus Professor of Anatomy in University College, London, from 1850 to 1877, and thus an interesting link with the past is maintained." Ellis was professor at U.C.L. from 1850 to 1877, and lived in seclusion as professor emeritus to the end of the century. Even anatomists cannot look forward to half a century on the shelf.

Ellis was succeeded in the chair by Sir George Dancer Thane, who held it until 1919. Ellis had edited the 6th edition of *Quain's Anatomy* with William Sharpey, the dominating professor of physiology. Ellis's *Manual of Dissection* reached its high-water mark in its 10th edition by Thane in 1887. Keen states that all the important figures are based on the *Illustrations of Dissections* published by Ellis and G. H. Ford in 1867. Anyone acquainted with Thane's work in the 9th and 10th edition of the Quain would recognize the number of illustrations by his hand in the 10th edition of the Ellis—e.g., that of the brachial plexus (Fig. 5).

Thane steadfastly objected to splashes of colour as a means of showing the origins and insertions of muscle on badly

executed drawings of bones. Addison, who re-edited the Ellis in its 12th edition in 1905, introduced these vulgarisms. All their inaccuracies have been maintained. The vastus intermedius (Figs. 47 and 48) is shown arising from the whole of the shaft of the femur, with no trace of the bare area. Examples could be multiplied. The section on the autonomic system is unintelligible and contains such phrases as, "The nerve cell of the 2nd neurone is often called the cell station," and, "The second neurone is the nerve cell in a ganglion and its axon, the fibres being non-medullated." The marginal or shoulder index which was so valuable a feature of the 10th edition by Thane has been deleted. Small paragraphs of doubtful value have been added in various places under the heading "Applied Anatomy." There is no mention of radiological anatomy.

It is sad to think that Thane's 10th edition of the Ellis and the 10th edition of the Quain (1896) by Thane and Sharpey Schäfer mark the high water of the tide of British anatomy. This present edition by Keen is a sad ebb from Thane's purpose—"to maintain the efficiency of the work as a guide to the acquisition of knowledge by practical study." Thane was the last of the precisionists. We are now in the hands of the confusionists.

CHILD GUIDANCE

Psychotherapy in Child Guidance. By Gordon Hamilton (Pp. 340. \$4.00 or 22s.) Columbia: University Press. London: Geoffrey Cumberlege (Oxford University Press). 1947.

In this book the author describes the methods and practice of the children's department of the Jewish Board of Guardians in New York. It is perhaps an unusual book in that it is written by a social worker and that in this clinic the social workers do the treatment in close collaboration with a psychiatrist. Since so many problems of behaviour in children are predominantly social, this is not illogical so long as the collaboration is really close, for the personal make-up of the child and his environmental situation are so closely blended. The treatment here described is eclectic and may be adapted to each individual problem. Although psycho-analytic theory is conspicuous in the book, the author does not consider that psychotherapy is synonymous with psycho-analysis or that it need be confined to medical methods. The psychiatrist, in fact, is regarded as a teacher and consultant rather than a direct therapist.

The author recognizes that in every case it is necessary to meet elemental social needs but that affect hunger may be as important as physical hunger. Both psychological and physical distresses are arcs of the same circle. The child is a growing organism and therefore adaptable, but both the social setting and the child's personality, which will always interact, may need adjustment. It should be remembered that a child's aggressiveness is always retaliation which to him seems justified. Many children have little experience of love, and so love is not worth seeking; the child feels that he must look after himself first. It is no use telling such a child to be good for a change; he and his circumstances must be changed if he is to be good. The anxious child is a neurotic child who uses his energy to repress infantile wishes. The resolution of such a conflict both increases energy and diminishes anxiety. Fortunately such a child wants to be helped and does not resist assistance. Severely disturbed children such as mental defectives and psychopaths are not very amenable to psychotherapy, but social adjustment may do much good. In direct treatment transference, catharsis, and relief through play are important, but social modification is generally necessary as well, and change of environment may alone restore the integrity of the personality.

Young children have many emotional vicissitudes to face, and they may react to them by disturbed behaviour, which in turn upsets the parents, so that a vicious circle is set up. Therapy must get beneath the aggressive and guilt reactions to the fundamental attitude, which is always that of a disappointed child. This is best done by play, because it is the little child's medium of communication and because it provides in a safe and natural way some of the instinctual gratification needed as he learns to meet the demands of reality. At the same time the parents, especially the mother, who are themselves neurotic need guidance and treatment. In older children the situation is more complex and can best be treated by transference,

interpretation, and verbalization, and again by increasing the understanding of the parents. In adolescence the strength of the urges and repressions is increased and the young person has at this stage to make entirely new adjustments to life. A strong, carefully managed transference is the best form of treatment so that the patient can be brought to understand and interpret his own difficulties.

In dealing with the family the social worker has to realize the complexity of the situation, for the parent is often projecting his own guilt or aggression or desire for punishment on to the child, and so the entanglement becomes very difficult to unravel. She has to establish transference with the whole family and so allow them to work out their difficulties and re-establish an integrated whole. To do this the social worker needs a long and elaborate training under expert psychiatric guidance, and she will of course learn both the social and psychological aspects of her task while undertaking the case work.

This is an interesting account of a successful venture in the care of difficult and delinquent children by methods rather different from those usually used in Britain. It is therefore worthy of the most careful study by those interested in the subject.

GLOMERULAR NEPHRITIS

Glomerular Nephritis: Diagnosis and Treatment. By Thomas Addis, M.D., F.R.C.P.Ed. (Pp. 338. £2.) New York and London: The Macmillan Company. 1948.

The impression which this book leaves with the reader is almost that of an autobiography, the summing up of one who has spent most of his life in the study of renal disease. Addis, we feel, is a man with a message who wants to give the medical world this record of his teaching and research. If the book is not wholly satisfactory it is perhaps because it tries to combine the two, while its autobiographic style is too discursive for either. Parts of the book are didactic and dogmatic, others strictly scientific and experimental; others again are practically in narrative form—as for instance the description of the life and death of a nephritic patient, which almost brings tears to the eyes. In spite of these defects—or should we say peculiarities?—Addis of course speaks with great authority and has much to say.

The chief subjects which he discusses are his rapid methods of biochemical and microscopical examination, specially designed to be suitable for use in an out-patient clinic, to give immediate answers to questions of prognosis and treatment; a description of the experiments which have been made by his team on the effects of removal of renal tissue in animals, and the inferences which can be drawn from this work; and a plea for low protein intake in the treatment of renal insufficiency. In America pendulums probably swing further than they do in this country, and it is evident that in many clinics all cases of renal disease irrespective of their clinical state have been given high protein diets. Addis, we think, brings conclusive evidence based on animal experiment to show that this is wrong, and that many cases of renal failure can be improved and kept leading useful lives for a long time on a suitably restricted protein intake. Most recent authors both here and abroad share this view. We found the experimental sections most interesting; there is information here which is difficult to find in convenient form elsewhere. Although, as we have observed, the book is not wholly successful either as a textbook or as a record of research, it must be read by all serious students of renal disease.

ROBERT PLATT.

The *Practitioner's Card-Index Guide to Treatment* is an ingenious file of notes on modern medical treatment of interest to the busy practitioner published by Devereaux (Medical) Publications Ltd., of 36, Maiden Lane, London, W.C.2 (5 guineas). The notes are filed on strong cards contained in a box, and the information is kept up to date by new cards distributed quarterly. The initial cost includes a year's replacement of cards; subsequently the cost of the replacement service is two guineas a year. The cards are arranged alphabetically and show the references in the literature to the treatment described.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Encyclopedia of Medical Sources. By E. C. Kelly, M.I.F.A.C.S. (Pp. 476. 41s.) London: Baillière, Tindall and Co. 1948.

A collection of references to medical eponyms and original reports.

Bright's Disease. By H. A. Christian, A.M., M.D., LL.D., Sc.I. M.A.C.P., Hon.F.R.C.P.(Can.), D.S.M. (Pp. 327. 45s.) London: Geoffrey Cumberlege. 1948.

Reprinted from *Oxford Loose-Leaf Medicine*.

An Atlas of Bone-Marrow Pathology. By M. C. G. Israë. M.Sc., M.D., M.R.C.P. (Pp. 79. 30s.) London: Heinemann. 1948.

An illustrated account of the marrow in health and disease.

Detailed Atlas of the Head and Neck. By R. C. Truex, M.S., Ph.D., and C. E. Kellner. (Pp. 162. 75s.) London: Geoffrey Cumberlege. 1948.

Anatomical illustrations.

The Family and Democratic Society. By J. K. Folsom. (Pp. 755. 30s.) London: Routledge and Kegan Paul. 1948.

A comprehensive study of family life in the modern democracy.

Rational Medicine. By J. W. Todd, M.D., M.R.C.P. (Pp. 378. 25s.) London: Simpkin Marshall. 1949.

Medicine regarded from an original approach.

A Short Practice of Surgery. By H. Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.Ed., and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., F.I.C.S. 8th ed. Part 4. (Pp. 179. 52s. 6d. for five parts, not sold separately.) London: H. K. Lewis. 1949.

Part 4 deals with the surgery of the head, spine, peripheral nerves, breast, thorax, larynx, and hand.

Health Instruction Yearbook 1948. By O. E. Byrd, Ed.D., M.D. (Pp. 320. 20s.) London: Geoffrey Cumberlege. 1948.

Information collected from health articles published in the last year.

A Guide to Pacific Island Diets. Edited by J. C. R. Buchanan, M.D., F.R.C.P.Ed., D.I.M.&H. (Pp. 75. No price.) Suva, Fiji: Pacific Board of Health. 1947.

A handbook for dietitians and doctors of the South Pacific.

Roentgen Studies of the Lungs and Heart. By N. Westermarck, M.D. (Pp. 216. 35s.) London: Geoffrey Cumberlege. 1948.

A fully illustrated account.

Manual of Clinical Laboratory Methods. By O. E. Hepler, Ph.D., M.D. 4th ed. (Pp. 387. 45s.) Oxford: Blackwell Scientific Publications. 1949.

A book of reference for laboratory and clinical workers.

The Invert and His Social Adjustment. By Anomaly. 2nd ed. (Pp. 290. 8s. 6d.) London: Baillière, Tindall and Cox. 1948.

An enlarged and revised edition of a book first published in 1927.

Demonstrations of Physical Signs in Clinical Surgery (Part IV). By H. Bailey, F.R.C.S., F.A.C.S., F.I.C.S., F.R.S.Ed. 11th ed. (Pp. 121. 8s. 6d.) London: Simpkin Marshall. 1949.

The fourth part of this well-known book for students.

An Introduction to Clinical Orbitometry. By A. C. Copper, M.D. (Pp. 125. Paper 11s. 6d., cloth 14s. 6d.) Leiden: H. E. Stenfort. 1948.

English translation from the Dutch.

Experimental Immunochemistry. By E. A. Kabat, Ph.D., and M. M. Mayer, Ph.D. (Pp. 567. 45s.) Oxford: Blackwell Scientific Publications. 1949.

Deals mainly with laboratory technique.

The Renal Origin of Hypertension. By H. Goldblatt, M.D., C.M. (Pp. 126. 15s.) Oxford: Blackwell Scientific Publications. 1949.

A short monograph.

NATURAL CHILDBIRTH

At a time when the topic of analgesia in labour has aroused not only public interest but political feeling, a recent address by Dr. Grantly Dick Read, the substance of which appears in our columns this week, serves as a reminder that there is another approach to the pains and discomforts of childbirth. Dr. Read has pertinaciously and with enthusiasm advocated for over fifteen years the case for "natural childbirth," and though many obstetricians would deny to his thesis the importance which he himself accords it he has not lacked adherents and followers on both sides of the Atlantic; and a recent report^{1,2} on his methods from the Yale University School of Medicine supports his contention that normal labour, by which is implied a vertex presentation with the occiput anterior and no mechanical obstacle, should be virtually painless.

The basic argument is that fear, conscious or subconscious, causes a sympatheticotonia which shows itself locally as a resistant lower segment and cervix. This, he says, is because the circular inhibitory fibres of the cervical "sphincter," which are innervated by the sympathetic and which should be relaxed when the longitudinal fibres of the upper segment exert their detrusor action, are thereby stimulated to chronic contraction. In turn the longitudinal fibres in an effort to overcome the obstacle increase their tension, and thus the threshold of pain is overstepped. "A tense woman means a tense cervix and a tense cervix means a prolonged and painful labour."

Not everyone will agree that this argument is scientifically correct on anatomical and physiological grounds, but its advocates claim that it can be accepted because in practice the results are successful. It is admitted, however, that the application of the principles cannot be universal, because there is a small proportion of women who are "unteachable." In brief, instead of the more commonly employed method of breaking the fear-tension-pain sequence by analgesic and anaesthetic drugs in labour, the cycle is interrupted at the first stage of fear by antenatal education. This is not an entirely new doctrine. In 1932 Fairbairn³ wrote: "The presentation to the woman's mind of childbirth as a natural process must be a guiding principle throughout all talks and examinations. Many women approach pregnancy and labour with a view distorted by what they have heard or seen of the terrors of labour. These difficult cases require careful consideration from the psychological side and will benefit by confidential talks in which may be revealed hidden dreads that might interfere with normal function." And in fact, after a phase in ante-

natal obstetrics in which the attendant was unduly preoccupied with the recognition of mechanical difficulties and the early detection of abnormalities, it is now true to say that there is more emphasis on the normal, on the teaching of techniques of relaxation, on the explanation of the mechanism of labour, and on how best to aid the natural forces. Obstetrics, as Dr. Read says, is the understanding of the mind as well as the body of the pregnant woman. In labour his practice—based on the recognition of the successive emotional phases—is to keep the patient informed of her progress, to ensure that she is not left alone without either doctor or nurse trained in these methods, and to reinforce the previously taught techniques of relaxation at the crucial times.

The advantages which are claimed for natural childbirth lie in the increased proportion of spontaneous labours in which the risks of anaesthesia and analgesia are avoided, and in the psychological satisfaction which the sense of achievement brings to the mother and indirectly to the baby. Natural childbirth is based primarily on an intimate doctor-patient relationship. And in this lies both advantage and disadvantage, for the personality of the individual doctor must be a very potent factor in the assurance of success, and unless the doctor is present during most of the labour many patients will lose control and experience pain. It is unfortunate that the present combination of district antenatal clinics with institutional delivery largely precludes the same doctor supervising both pregnancy and labour, and these and other practical difficulties are well illustrated by the disappointing results obtained by Rodway⁴ in a controlled experiment on the value of antenatal exercises. The general-practitioner obstetrician has the greatest opportunity for putting these principles into practice and assessing their value.

As with all doctrines, Dr. Read's argument and practice will have adherents but will not lack detractors. Many of his principles, especially his emphasis on the effect of the emotional factor on the course of labour, are universally accepted, though the exact mechanism may be debated; and, if some consider that he has oversimplified the problem and been too optimistic about its solution, others will be encouraged to take up a more personal form of obstetric practice which alone will achieve results satisfying to both doctor and patient.

DUE CARE AND SKILL

Mr. John Hunter's successful appeal against Mr. Justice Birkett's judgment awarding* an ex-patient £6,300 against him for negligence raises again the perennial question of what in law constitutes negligent diagnosis or treatment. We have already published full accounts of the proceedings at first instance¹ and on appeal.² Briefly, Mr. J. F. Whiteford, an American consulting engineer of about 65, was in the care of Dr. S. R. Gleed, a general practitioner of Finchley, who called in Mr. Hunter. He drained the patient's bladder suprapubically on March 22, and operated on April 5, 1942. He found in the base of the bladder an indurated mass which, after he had inspected and handled it for a quarter of an hour or twenty minutes,

² Thoms, H., *J. Obstet. Gynec. Brit. Emp.*, 1949, 56, 18.

³ *Practitioner*, 1932, 129, 313.

⁴ *J. Obstet. Gynec. Brit. Emp.*, 1947, 54, 77.

he decided was an inoperable cancer. Subsequently Mr. Hunter informed the patient that he had not long to live. Mr. Whiteford then returned to the United States to put his affairs in order. In September he was seen by a New York urologist, Dr. B. S. Barringer, of the Memorial Hospital, and Mr. Hunter's diagnosis was proved wrong by biopsy and also by the survival of the patient. Mr. Whiteford returned to England and sued Mr. Hunter and Dr. Gleed for negligence. The judgment against Mr. Hunter was given in July, 1948, the action against Dr. Gleed being dismissed. At the recent appeal the judgment was reversed, and leave was given to Mr. Whiteford to appeal to the House of Lords. As the case is still *sub judice*, it would not be proper to comment in such a way as to prejudge the issue, but it is permissible to inquire what that issue is, and to examine the approach to it made by the trial judge and by the Court of Appeal.

The question which the courts had to decide was not whether Mr. Hunter's diagnosis was wrong—that was admitted. The issue before them was whether, on the evidence, Mr. Hunter had failed to use the skill and care which could reasonably be expected of a practitioner in his position. The standard expected of such a well-known senior consulting surgeon is a very high one, but it still does not require him to be infallible. It was pointed out in the Manchester swab case,³ just before the war, that "it is not every slip or mistake which imports negligence, and in applying the duty of care to the case of a surgeon it is peculiarly necessary to have regard to the different kinds of circumstances that may present themselves for urgent attention." Accordingly the courts had to consider the standing of Mr. Hunter, the skill which he offered to the public, the quality of the services which a patient had a right to expect of him, and then, so far as possible putting themselves in his place and visualizing the situation in which he found himself, they had to judge whether on a reasonable view he did all that could have been expected of him in that situation. The trial judge found that he did not, and the Court of Appeal found that he did, use able skill and care in the circumstances.

The issue was in fact narrowed down to two questions:

1. Should Mr. Hunter have used a cystoscope? and, Should he have performed a biopsy? There was no dispute that clinically the submucous inflammatory condition from which the patient was suffering may be practically indistinguishable from cancer. In his own evidence Mr. Hunter said that he did not habitually use a cystoscope in cases of this kind, and that he did not find it convenient to use it. At the operation itself there would have been no opportunity for using it, as he was about to see the bladder directly. When asked why he did not perform a biopsy, he replied that he had decided not to do so for three reasons. He

The *Practitioner's Case* had to cut so deeply that there would be no use of notes on models. The busy practitioner published by the London of 36, Maiden Lane, Ltd., of 36, Maiden Lane, London, are filed on strong cards containing the latest up to date by new cards distributed. It includes a year's replacement of cards; the replacement service is two guineas a year, and the treatment described.

satisfied, for he would have suspected that he had not taken the specimen from the right part of the lesion. Expert witnesses supported Mr. Hunter.

Apart from the cross-examination, the only medical evidence for the patient was that of Dr. Barringer. This had to be taken in New York on commission, a process which is open to obvious and inevitable disadvantages. Counsel for both sides pose questions in examination and cross-examination as in court, but the evidence suffers from being taken outside its proper context in the trial, and nearly always lacks answers to essential questions which probably would have occurred to counsel and to the judge if the witness had been present in the ordinary way. Dr. Barringer's evidence suffered from these disadvantages, and this trial is to that extent prevented from being a clear-cut object-lesson in the law of medical negligence. The chief difference between the trial judge and the Court of Appeal was in their respective assessment of the evidence taken on commission as it appeared in the official record. Mr. Justice Birkett laid great stress on Dr. Barringer's statement that the diagnosis should have been verified by a complete examination with the cystoscope and through the open bladder, with a pathological examination of any questionable areas. He accepted this statement against Mr. Hunter's reasoning, and accordingly held the mistake in diagnosis to have resulted from lack of reasonable care, particularly in not using the cystoscope and in not undertaking a biopsy.

The Court of Appeal, on the contrary, could not support the trial judge's finding that the cystoscope should have been used on April 5, when the inside of the bladder was going to be observed by direct touch and sight, and regretted that this point had not been put more clearly to Dr. Barringer by counsel in New York. Their Lordships said, too, that, far from being clear and unambiguous, Mr. Justice Birkett described some of Dr. Barringer's evidence, it contained many ambiguities, and they pointed out several omissions of points with which they wished counsel in New York could have dealt. They felt that in several respects Dr. Barringer had been directing his attention, not to the condition which Mr. Hunter had had to deal with, but to the very different condition which Dr. Barringer himself had found several months later. They therefore held that the trial judge should not have accorded such decisive importance to Dr. Barringer's evidence, and they could not support his finding that Mr. Hunter had been negligent in not carrying out a cystoscopy and biopsy.

The circumstance that the chief evidence for the patient had to be taken on commission has another bearing apart from the quality of that evidence. Normally a witness observed under examination and cross-examination, will not readily differ from the trial judge on his assessment of the value of their evidence. In the present case, as the trial judge did not see this important witness nor have the opportunity of questioning him, the Court of Appeal could feel itself just as well able as the trial judge to examine the record of his evidence and to assess its value. The two courts differed fundamentally over the interpretation of that record, and if the case goes

o the House of Lords judgment will doubtless be brought o bear upon it afresh. Upon that judgment the ultimate result of the case is bound in large measure to depend.

THE BUDGET AND HEALTH

The cost of the social services was the recurrent theme in Sir Stafford Cripps's Budget speech. He rebuked those who, while demanding costly social services, at the same time asked for reduction of taxation. "Last year," he said, "the people of this country enjoyed an unexampled national dividend in the form of a free National Health Service at the cost for nine months of its duration of £208 million. Next year, for 12 months, it is estimated to cost £268 million." The education and health services in England and Wales and Scotland, national insurance, and national assistance would provide benefits amounting to £763 million. This, the Chancellor said, must be reckoned as a real saving to the individual. "But the cost in 1949 was not the end." At present 60,000 hospital beds were out of use because of want of staff; to make them available once more would cost £15-£20 million. These services had to be paid for out of direct and indirect taxation. He gave the warning, however, that the speed at which the social services expanded must be moderated in accordance with "our progressive ability to pay for them by an increase in our national income."

The N.H.S. is an important part of what the Chancellor called "a permanent and continuing obligation which automatically increased as those services inevitably developed." Seeing, and perhaps fearing, this automatic and inevitable increase, he hinted that next year he might have to impose "some special charge or tax in connexion with the health services . . . this might help to make people more economical in their use of the services." In discussing the supplementary estimate in the *Journal* of Feb. 19 this year we wrote: "The Government may yet consider it wise to ask the patient to make token payments for a doctor's services and for prescriptions. If this were considered feasible it would deter people from making unwarranted calls upon the doctor's time and unnecessary demands for pills and potions." With increasing control of infectious diseases—witness the slackening of work in the fever hospitals as a result of the diminution of diphtheria—and the promotion of health, the increase of medical services should not need to be "automatic" and "inevitable." Automatic and inevitable increase is more likely to occur in the administration of the services; establishments grow like coral reefs. The medical profession will want to keep a sharp eye on the size and cost of the administrative machine. To take two items—how many thousands of pounds will be spent in one year to enable the Spens Awards Committee to distribute its prizes? How many valuable medical man-hours will be spent unprofitably in interminable committee meetings?

Sir Stafford Cripps made one comment in his broadcast on April 6 which seemed to imply that the present Government had contributed to the fall in infant mortality. "And these improved social services—the better care of our

children in particular—have," he said, "had remarkable results. Do you know that infant mortality is now less than two-thirds of what it was ten years ago? . . . We have very deliberately chosen this most sure way of increasing the health and happiness of our people. . . ." Can Sir Stafford Cripps really be ignorant of the fact that the infant mortality curve has fallen steadily and evenly for the past fifty years,¹ years in which Labour Governments have been conspicuous by their absence. He might just as well, and with equal relevance, have attributed "to these improved social services" the increase in juvenile delinquency.

LIGATION OF THE INFERIOR VENA CAVA

Ligation of the inferior vena cava is a certain method of preventing pulmonary embolism in all but a few cases, since more than 95% of such emboli come from the lower limbs and the majority of other emboli arise in the pelvic veins. Thebaut and Ward¹ have reported a series of 36 cases of ligation of the inferior vena cava and recommend this as the treatment of choice in patients with thrombo-embolism. While many would not entirely agree with this recommendation there can be no doubt that in selected cases ligation of the inferior vena cava is a valuable operation. The four deaths in Thebaut and Ward's series were in advanced cases in which the operation was undertaken too late, and two of their patients died at operation before the vena cava had been tied.

For those who rely solely on the anticoagulant drugs or on vein interruption at lower levels ligation of the inferior vena cava may seem an unduly radical method of treatment. Ligation of the superficial femoral and of the common femoral veins is, however, followed by embolism in a small proportion of cases, these emboli arising either from the deep femoral veins, the pelvic veins, or from the ligated veins at a higher level. Theoretically a strong case can be made out for ligation at the highest possible level, but against this must be set the undoubted risks of the operation in some of those cases in which the indications for it are strongest. Ligation of the inferior vena cava just above its origin is technically no more difficult than an extraperitoneal lumbar ganglionectomy on the right side and, as in that operation, is most easily accomplished through a transverse incision at the level of the umbilicus. The intraperitoneal operation is more difficult and dangerous, and it should be reserved for those cases in which the vena cava is ligated in the course of some other abdominal operation.

Swelling of the legs after ligation of the vena cava is often seen, but usually is not permanent. Persistent oedema in those few cases in which it occurs is rarely severe enough to incapacitate the patient. Much of this swelling may be due to further thrombosis rather than mechanical interference with the circulation, and adjuvant treatment with anticoagulant drugs is therefore essential in some cases. Despite the apparent profusion of the alternative venous channels available,² careful anatomical study has shown that the arrangement of the venous valves, directing blood flow towards the parent vessels, frequently bars the use of certain anastomotic channels until they have become so distended that the valves are rendered incompetent.³ Interesting studies of the venous pressure in the legs have

¹ *Martin, W. J.*, *British Medical Journal*, 1949, 1, 438.

been made,^{1,5} and it has been shown that despite greatly increased pressure oedema is usually slight. Furthermore, though the oedema tends to disappear after several months, the venous pressure may remain high for several years. The circulatory adjustments seem adequate, and no detrimental effects are seen; but the compensatory mechanism involved is incompletely understood.

If ligation of the inferior vena cava is to be used more generally it is important that cases should be carefully selected. When embolus has already occurred and there is an undoubted or possible pelvic thrombosis the operation is clearly indicated; satisfactory results have been recorded in gynaecological cases,⁶ and the ovarian veins too have sometimes been ligated.⁷ When an embolus arises from an unknown source and vein interruption is indicated, the vena cava is the site of election. A further indication for the operation is recurrent embolism after ligation of the femoral veins. Prophylactic ligation of the vena cava may be justifiable during an abdominal operation such as ureteric transplantation for carcinoma of the bladder on the grounds that two major operations constitute a special risk.

Delay in undertaking operation may greatly increase its danger in cases of repeated embolism. Thus death occurred in 9 out of 21 cases reported by Moses,⁸ and, while it is certain that some of the survivors would have died from embolus had operation been withheld, it is likely that there would have been fewer fatalities if the only treatment adopted had been the administration of anticoagulant drugs. Before deciding on an operation of this severity the surgeon must be convinced that the treatment is not more risky than the condition which it sets out to control. There can be no doubt, however, that ligation of the inferior vena cava, wisely and properly practised, will prove a valuable weapon in the conquest of pulmonary embolism on those few occasions when anticoagulant therapy is impracticable or impossible. With adequate supplies of heparin available it would seem unlikely that ligation of the inferior vena cava will be widely practised by surgeons in this country.

SYNTHETIC CHLORAMPHENICOL (CHLOROMYCETIN)

Although some penicillins have been synthesized and new penicillins have been created by the chemists, the processes involved are complex, and synthetic penicillins have not yet come into general use. Controulis, Rebstock, and Crooks,¹ however, have recently synthesized chloromycetin, to which the name chloramphenicol has now been given.

We have already referred to early reports on the use of this drug in infections in man.^{2,3} Encouraging results have been obtained in typhoid fever,⁴ typhus fever,⁵ scrub typhus,⁶ and Rocky Mountain fever.⁷ The synthetic product, the structural formula of which is here shown, is (1)-ψ-1 p-nitrophenyl-2-dichloroacetamidopropane-1:3-diol; it has apparently the same physical and chemical properties as the chloramphenicol produced by the mould *Streptomyces venezuelae* n.sp. Smadel and his colleagues⁸ have reported that the synthetic product has an action on rickettsiae and viruses in developing hens' eggs,

mice, and human beings which is identical with that of the product produced by the mould. In developing hens' eggs two doses of the synthetic and natural products produced prolongations of the lives of the chick embryos the mean values of which were practically identical. This was true for: *Rickettsia prowazekii*, *R. mooseri*, *R. rickettsii*, *R. akari*, and two strains of *R. tsutsugamushi*, as well as for lymphogranuloma venereum and two strains of psittacosis virus. Mice infected with the Karp strain of *R. tsutsugamushi* receive a single daily intraperitoneal injection of solutions of the two types of the drug varying in amount from 0.375 to 2.5 mg. per day per mouse; both types effectively prevented death. Similarly, feeding both types of drug to mice infected with psittacosis virus gave results which were identical with those obtained with the natural antibiotic. Finally, two patients with scrub typhus in Kuala Lumpur have been treated with synthetic chloramphenicol. Both patients received the drug orally over a period of 16 hours; the initial doses were 3.0 or 4.0 g. followed by 0.25 g. at three-hourly intervals. The clinical response was the same as that observed in other cases of scrub typhus treated with the natural antibiotic, and there were no toxic reactions. Synthetic chloramphenicol is now being tested prophylactically against scrub typhus in Malaya.

The synthesis and clinical use of an antibiotic obviously an event of considerable importance, since it opens up fresh fields for the ingenuity of the synthetic chemist. Incidentally, it will be necessary to enlarge the scope of the word antibiotic unless it is to be dropped altogether. Hitherto the term has been applied only to naturally occurring substances endowed with chemotherapeutic powers and produced by micro-organisms during their growth and metabolism.

THE TONGUE IN VITAMIN-B DEFICIENCY

Dietary deficiencies of nicotinamide, riboflavin, pyridoxin and biotin are each reported to have caused lesions of the tongue, which are also common in diseases associated with nutritional disturbance, such as pernicious anaemia, sprue, and other intestinal disorders. These lesions can now be detected at an early stage by inspecting the tongue under ultra-violet irradiation screened with Wood's glass. The appearance of the normal tongue under irradiation was described 20 years ago by Bommer,¹ who observed a red fluorescent coating on the lingual dorsum. Later Radley and Grant² reported that the mucous membrane of the tongue shows a greyish or yellowish-white fluorescence, while towards the back the fluorescence is often red or orange. The possible nutritional significance of the fluorescence, however, was not at first realized, though Costello and Luttenberger³ were aware of reports that the fluorescent coating disappears in vitamin-B deficiency. In following up this clue Hagerman and Hirschfeld⁴ have recently examined over 543 patients attending a dermatological out-patient clinic. In 155 patients the fluorescence extended over the entire lingual dorsum, and in another 174 at least half the area was covered. These 331 cases were considered normal, while the remaining 212 cases, in which the fluorescent coating was defective or absent, were considered abnormal.

All the cases, without reference to the fluorescence of their tongues, were next divided into two groups according to whether their skin diseases were or were not considered

be associated with vitamin-B deficiency. Unfortunately the authors do not clearly describe the method used to come to a decision in each case, but fungous infections, dermatomas, and infestations were considered not to be related to vitamin-B deficiency. When the two groups were compared the proportion of cases with abnormal fluorescence of the tongue was found to be significantly greater in those with diseases supposed to be associated with vitamin-B deficiency than in those with the other skin diseases. In addition, the authors observed that the tongues of patients who had been dosed with B vitamins before coming to hospital usually showed normal fluorescence, irrespective of the nature of their skin disease. They therefore gave vitamin-B preparations, either orally or by injection, to 196 of the patients with abnormal fluorescence of the tongue; in 141 of these the abnormality disappeared. Parenteral therapy appeared to give better results than oral, and vitamin-B preparations containing pantothenic acid were much more effective than those not containing this factor.

Possibly this method of examination could be used for the diagnosis of the vitamin-B deficiency, but further careful investigation will be necessary before the significance of defective fluorescence is fully understood. It is not clear, for example, whether the abnormality results from deficiency of one particular B vitamin, presumably pantothenic acid, or whether it may also be caused by lack of other B vitamins. However, the possible effects of age and other factors unrelated to nutrition must not be overlooked. Similar difficulties have arisen in attempts to distinguish abnormalities of the tongue visible in ordinary light which are thought to be associated with vitamin-B deficiency. Thus Bakwin and his colleagues² examined the tongues of 60 children over an extended period and classified the lesions as acute glossitis, glossitis migrans, mild swelling of the tongue, and fissures of the tongue. The diets of these children were not demonstrably different from those of similar children without tongue lesions. In some of the children with swollen and fissured tongues improvement followed the administration of nicotinamide, though none were completely cured even after prolonged treatment. Glossitis migrans was unaffected by nicotinamide, and acute glossitis improved spontaneously or after chemotherapy. From these observations they conclude that the lesions of the tongue commonly seen in children in the U.S.A. are not due to deficiency of nicotinamide, though its administration may be beneficial. The conclusions reached by the Swedish and American workers, therefore, differ both in the degree of importance which should be ascribed to dietary deficiency in causing tongue abnormalities and in the selection of the B vitamin to which special importance is attached. With the wide differences present in the ages, diets, and circumstances of the groups of patients examined an explanation of this divergence of view might not be hard to find. It is obvious, however, that this is a complex problem, and the results of these and similar investigations must be interpreted with caution.

DUPUYTREN'S CONTRACTURE

Though Sir Astley Cooper¹ appears to have been aware in 1822 that the deformity now known as Dupuytren's contracture was confined to the palmar fascia, Dupuytren² was the first surgeon to investigate this condition by dissection and thereby reveal its true site. Since then various theories have been advanced to explain its nature, and recently Tord Skoog³ has made a special study of the deformity at Sir Archibald McIndoe's plastic surgery unit at East Grinstead and at the University of Uppsala in

Sweden. His investigations have shown that the palmar aponeurosis is most strongly developed on its ulnar aspect and that this tissue has a poor blood supply and is sparsely supplied with nerves. In movements of precision the plentifully muscled radial part of the hand is mainly used, while the ulnar side acts as a support and is thus more exposed to repeated and sustained trauma.

The condition occurs mainly in men, only 15% of the patients being women, and nearly all the patients are over the age of 40. The lesion becomes more severe with advancing years. It is mainly bilateral in incidence, and the ring and little fingers are chiefly affected, the appearance of a subcutaneous nodule in the palm being the first sign. The thumb is rarely involved, since in most hands the palmar fascia does not extend to this digit. The condition progresses slowly if untreated, and though it remains confined to the palmar aponeurosis it produces secondary changes in the contracted joints. Skoog gives evidence that trauma is the most important aetiological factor. Histological examination shows richly cellular areas of connective tissue containing blood pigment in the fascia; as the connective tissue degenerates with advancing age it loses its elasticity and is replaced by dense collagen bundles; thus the retraction characteristic of the condition is produced. Skoog mentions the association of Dupuytren's contracture with knuckle pads, and he believes that the frequency with which the condition occurs in epileptics may be connected with the prolonged administration of phenobarbitone. There is also undoubted evidence of a hereditary factor depending on dominance of low penetrability which is sex linked. Other aetiological theories have little to support them.

The best treatment is removal of the affected palmar fascia by operation, and Skoog favours Sir Archibald McIndoe's procedure. A transverse incision is made in the neighbourhood of the distal palmar crease. Where the fingers are affected a Z-shaped incision is used on the palmar surface of the finger over the proximal phalanx in order to lengthen the skin in this area. A tourniquet is essential to permit an accurate, gentle, and complete dissection. To remove completely the deep extensions and to avoid damage to the flexor tendons, vessels, and nerves, longitudinal incisions are made over these structures, which should first be identified outside the contracted mass of fibrous tissue and carefully followed through this tissue. Secondary changes in the finger joints will require prolonged and careful after-treatment, and in this connexion active movements must accompany splinting in extension. Splinting alone is dangerous, since the fingers quickly become stiff and the result of treatment is worse than the disease itself. The chief dangers to be avoided are post-operative haematoma and sepsis. Provided severe secondary changes have not already occurred the results of operative treatment have proved to be excellent. Many attempts have been made to find a reliable method of treating this condition without operation. A correspondent⁴ in the *Journal* recently drew attention to the value of radiotherapy.

Skoog also describes a similar condition affecting the plantar fascia in its medial part, in the region of the base of the first metatarsal and first cuneiform. Operative removal is rarely required, but when this is necessary excision should be confined to the diseased area. The dissection should not be widespread as in the palm owing to the danger of interfering with the integrity of the arches of the foot.

SOME OBSERVATIONS ON THE TEACHING OF PATHOLOGY IN THE U.S.A.

BY

K. R. HILL, M.D.

(From the Department of Pathology, Medical School, King's College, University of Durham, and the Royal Victoria Infirmary, Newcastle-upon-Tyne)

The recent report of the B.M.A. Medical Curriculum Committee (*The Training of a Doctor*, 1948; Butterworth, London) has raised many controversial points which will be disturbing to some and welcome to others engaged in the teaching of medicine. It may be of interest at this time to study methods of teaching in other countries, and it is proposed, therefore, to comment on teaching in America, confining myself to one subject only, pathology. I recently spent a year in the pathology department of a well-known American teaching hospital, and during this time was able to visit and study methods at five other widely separated teaching institutions, two of them State university medical schools.*

At the outset it must be mentioned that in the U.S.A. medical students (excluding ex-Service men) are, on the average, three years older than their British counterparts. Most American students have taken a degree in arts or science (often including physics, chemistry, and biology) before entering medical school, which they do at the age of 21 or over. Probably as a consequence of being older and having had a university education, American students are more mature in outlook and have a more lively sense of the value of their studies in pathology and its application to medicine than English students. There was no evidence of previous cramming, and the scientific knowledge garnered in preceding years was often applied to the problems of pathology with an eagerness which led students into research projects as undergraduates.

Whether or not it is desirable to insist on a university degree as a necessary qualification before taking up a medical training is debatable. Although this is generally done in America, it is interesting to record the fact that wherever I went I found that the English medical student (and doctor) had a high reputation for general culture. The batch of undergraduates who were trained in the U.S.A. during the war enhanced the reputation of British students immeasurably. Further, one eminent pathologist and teacher told me that the English system of going straight from school to medical training was the best, as it enabled the student to get rid of his factual training quickly and then settle down to doing real useful thinking and worth-while work (e.g., research, postgraduate specialization) before the age of 30.

After entrance the general medical course consists of four years' graded instruction, at the end of which an examination for the M.D. degree is taken; then follows a year's internship. The four-years course is carefully integrated as a whole, and generally consists of: first year, anatomy and physiology; second year, pathology and associated subjects; third and fourth years, clinical subjects. During the preclinical and very often during the clinical period of training, instruction is carried on throughout the academic year of about eight months with very little break for vacation. Often the long vacation is filled in taking an extra elective course—e.g., obstetrics, pathology, or a research problem—but it also may be occupied in doing a job ("working one's way through college") or a military commitment.

Undergraduate Training in Pathology

Pathology is generally taught in the second year, and, though on paper it may be considered a preclinical subject, it is in practice never taught without the association of a hospital background, and the correlation between lesions and functional alterations is constantly stressed. Although the main course is in the second year, in many schools there is often systematic training also in the third year, and in all cases pathology is kept constantly in the students' minds during their clinical training by clinico-pathological conferences, pathology

staff conferences, special gynaecological pathology, etc., pathology, and "grand rounds."

Bacteriology, chemical pathology, haematology, and clinical biology (serology) are taught as separate subjects in their departments and not, as a rule, with pathology. The course in pathology may extend throughout the whole academic second year or may, as in some schools, be compressed in two terms.

In nearly all schools visited a systematic course of lectures was given. In one or two schools the lectures departed from the usual scheme and dealt only with recent theoretical or research aspects not yet appearing in the textbooks or aspects not generally emphasized by the textbooks—e.g., collagen-vascular diseases, deficiency diseases, etc.

One eminent authority told me that systematic lectures were a waste of time and that their only use was to give practice to the junior members of the staff in preparing their subjects and in lecturing before an audience.

Besides lectures there were classes in morbid anatomy and histopathology. In conducting these a feature which was quite common was the effort to bring together teacher and student in close personal relationship. The classes were divided into small groups, comprising not more than a dozen students, and a large number of instructors ensured attention to the requirements of the individual student.

Specimens representing each disease or group of diseases were concentrated in separate rooms, where for about four weeks they were studied by a group of students in turn under their instructors. In some cases the instructors remained with their particular group of students throughout the academic year, circulating through the different rooms with them. In others, specialists in the branch of pathology represented the specimens in the particular room dealt with each group of students as they came through.

The first method is much more personal—more akin to the "supervision" or "tutor system" that prevails in older universities. It leads to a more intimate relationship which helps to iron out the difficulties of the individual, and in practice particular groups put on a demonstration and discussion with their tutors which lasts into the late hours of the evening—often to finish up in the local beer-parlour! The advantage of the second method is that specialists are brought directly into contact with the student: neuropathology is taught by neuropathologists, gynaecological pathology by gynaecologists with an interest in the pathological side, and so on.

The specimens in the rooms were from necropsies going back many years, preserved in large jars of formalin. Thus in one room cases representing tuberculosis were collected; in another cardiovascular diseases, in a third genito-urinary diseases, and so on. The specimens were loose and were handled both by demonstrators and by students.

Mounted specimens were also used in these rooms for demonstration purposes. Some institutions had a museum of mounted specimens for teaching purposes, but I gained the impression that, generally, museums were for the housing of historical specimens and oddities rather than for teaching.

There was always an efficient filing system, so that reference could be made to the history and the microscope slides relating to the cases in the gross-specimen rooms. A very useful exercise within the groups was for one student to present a series of cases compiled from the files to illustrate a special feature of pathology.

Microscope slides and protocol files were never sacrosanct. I asked once if there was no concern over the loss of slides in this sort of system. I was told it was better to have the slides used and lost rather than never used at all, and so far as I could see there were comparatively few losses considering the amount of use the collections were given.

Concurrent with the study of gross specimens, histopathology relating to the group of diseases studied in each particular room was carried out. Nearly always a member of the staff was present, and the procedure was to alternate between gross-specimen rooms and microscopy rooms.

As a rule the student was given 200 to 400 representative slides portraying pathological processes, and histological

*I held a Rockefeller Fellowship at the Johns Hopkins Hospital, 1947-8, and visited the Universities of Chicago, Cornell, Harvard, Maryland, and Illinois.

Items were stressed rather than detailed cytology. As a consequence of this the micro-projector could be used, and is used extensively (in the U.S.A. the micro-projector always seems to be efficient); this I found was a distinct advantage indicating to the students the exact lesion under discussion. The micro-projector could be employed in this country much more extensively, not only by students but also for the purposes of illustrating lesions at clinical meetings.

Often the groups or the class as a whole had weekly recitations or "quiz" exercises similar to our "rags" or "bottle parties." They were a popular feature, and the students found them very instructive.

In all schools attendances at necropsies were given high importance. In schools using the group system of teaching, the group attended the necropsies performed by the group member of the staff. Embalming of bodies is often carried out in the United States, and as a consequence hospitals generally have a 24-hour necropsy service in order to accommodate the undertakers. It is not unusual, therefore, to see a group of students attending a necropsy into the small hours of the night with their staff member.

Generally the students assist the pathologist (doing the dirty work," such as the opening of the gut), but in some hospitals students may carry out complete necropsies under supervision. In several schools it was the practice for a team of four to take over a case, and later one would present the history, another would demonstrate gross specimens, another the histology, and a fourth would give the final commentary. The whole team was often responsible for the histology blocks being embedded, cut, and stained.

Often the necropsies of one day were presented next day or on specified days during the week, when the whole class or smaller groups attended. In general, specimens are preserved in formalin, although the use of the deep-freeze for gross specimens is on the increase; this method has the advantage of preserving the natural appearances when thawed.

One university makes extensive use of colour photography of gross specimens and has collected a very complete library of lantern slides, so that any disease can be quickly illustrated on the screen. Excellent though this may be, it has the very obvious danger of being so easy to use that it may exclude the seeing and handling of the actual diseased organs, which, to my mind, is so important in the teaching of pathology.

In passing it might be noted that, although many necropsy theatres have special galleries for students to watch the performance of a necropsy, I never saw one in use.

During all this time it is possible for a student, or several students together, to carry out a research problem, and many do so. This may consist of a compilation of post-mortem reports and material or pure experimental work on animals. I remember well at one institution, when Trueta's book on the renal circulation became so much talked about, two students approaching the professor of urology and asking if they could repeat some aspects of Trueta's work. They were told, "There is the lab.; get on with it." I asked if these students would get anywhere with the problem, and was told, "Probably not, but they will learn something and think for themselves. That is why they are here." This typifies the attitude of the whole medical staff of these teaching institutions, and it is an attitude which is not confined only to the pathology department.

In most of these institutions much more stress is put on experimental work than in England. More and more it may be said that the pathology taught in the States is functional pathology rather than just the study of "dead issues"—although morbid anatomy as taught by the German and Scottish schools is not neglected. To this end functional alterations are emphasized as much as the lesions for which they are the cause or with which they may be associated. As an example of this method of teaching, one institution names the practical part of its course "pathological anatomy and physiology," and states that the course is "meant to present systematically the anatomical, chemical, and functional changes which occur in the commoner human diseases." As a result the medical student is much more experimentally and research minded than his British counterpart.

Perhaps an extreme example of this has been reached at one institution where for one term groups of students are given experimental problems on animals—e.g., vascular occlusions, diet experiments, and so on—for the study of various cause-and-effect processes in pathology. This method of teaching functional pathology is as yet in its experimental stage, and its results are still *sub judice*. Opportunity for research is arranged for by the fact that courses are so planned that students are left with a third to a quarter of their course as free time.

One interesting aspect of the medical training is the elective course, in which a student voluntarily chooses to do pathology or some other subject. If he takes pathology he functions as a junior member of the staff (even though he be only a second-year student), performs necropsies (under supervision), and presents his completed case with the histology to the chief of the department. I was most impressed with this aspect, for I heard second-year students present their cases with the aplomb of many an experienced pathologist.

Throughout the clinical years the pathology department constantly influences the student in training. At least once a week, and often many times more, the student will view histological patterns of diseases shown on the screen by the micro-projector, see gross specimens, and hear them discussed at various hospital conferences. Further, he will attend special pathology classes, either compulsory or elective, in surgery, gynaecology, ophthalmology, dermatology, and neuropathology. One good method which is often practised is to bring in the clinician at these classes. The clinician reads out the case history, shows lantern slides and radiographs of the patient, and discusses prognosis; the pathologist in his turn demonstrates the gross specimen (or shows a lantern slide of it) and then discusses the histological pattern. This adds interest to an otherwise often uninteresting subject.

It is my impression that throughout his course the American student is much more histologically minded than his English counterpart. Certainly he does not have to learn a word-picture of a histological appearance from Boyd's textbook before his examination. These remarks also apply to the postgraduate in subjects other than pathology.

Postgraduate Teaching of Pathology

It is a not uncommon practice in the States for a student, after passing his M.D., to do his internship in pathology. It should be noted that up to the time of taking his M.D. he has had only two academic years of clinical training. To those who have gone through the gamut of the longer British training this early specialization in pathology after such a brief clinical training sounds incredible. I asked the doyen of American pathologists whether he thought this system was a good one; he replied, "It is unnecessary for embryo pathologists to waste time doing clinical jobs."

I formed the opinion that, in American teaching hospitals, once a specialist had completed his period of postgraduate training he tended to broaden his viewpoint by close association and frequent conferences with other departments. In England, on the other hand, although we insist on our specialists having a much wider background of initial training, perhaps they tend to tread the narrow path of their own specialty once they are established and the years roll on.

In my experience the training of pathologists was excellent. In the first place, juniors (or "residents") were accepted by the senior members of the staff as equals, although it was obvious that at first the senior members were talking right over their heads. This stimulus to, shall we say, self-respect and higher thinking paid dividends, and the progress of the trainee pathologists was phenomenal. Furthermore, the junior was straightway given a responsible job. For example, he would be sent to the surgical pathology department, for which he would be responsible for three months. His work was of course checked by a senior member of the department every day, but he was primarily responsible for the gross and microscopical descriptions of the specimens, and also did all the emergency frozen-section reports. A junior resident thus worked very hard, and during his tour of duty had almost a twenty-four hours day.

In the training of the pathologist necropsy work was all-important. The junior performed necropsies at first under supervision. A week after the necropsy he would present his report together with the gross specimens to a senior member of the staff, who in turn would dictate a further commentary. Some time later the junior would present the microscopical sections to this senior member of the staff; and, in passing, it may be noted that all special stains were done by the trainee pathologist himself. The senior member would write a final commentary or, if it was of particular interest, would put the case up for presentation at the weekly staff conference before the head of the department. At this conference the junior would present the case to the chief, who would write his final commentary. By this method of checking first at the gross-specimen stage, then at the microscopy stage, the facts were well inculcated; and when the chief discussed these facts and added his own observations emphasizing the importance of the pathological processes involved the case finally was nicely orientated within the resident's mind.

In addition to weekly conferences on necropsies there were intra- and inter-departmental conferences in which the junior members took part. One such conference was that of surgical pathology, at which the interesting histopathology of the preceding week was brought to the notice of the whole department. An excellent feature of this conference was the description of the patient given by a resident whose duty it was regularly to attend the tumour clinic where he had seen the patient. This resident at some other time would present the histopathology to the surgical staff of the tumour clinic.

The resident staff were also involved in the preparation and presentation of regular conferences held in conjunction with the paediatric and the obstetrical departments, at which infant and foetal deaths were reviewed respectively.

At one institution the pathology department would give a review of a particular disease or pathological process as it presented itself after examination of the hospital records. At the conference clinicians and pathologists would present their respective observations and conclusions (and these were often original) and a discussion would ensue. As the resident staff were often responsible for doing the "spade work" for such conferences they gained valuable experience in bringing together several aspects of pathology.

Within the pathology department one found, besides the trainee pathologists, trainee specialists from other departments, such as medicine, surgery, and radiology, who were there for instruction for one year. This added a leavening of "in" personnel which was very healthy and made liaison with other departments easier. At one institution the radiologists under training were utilized at all conferences to collect and interpret the radiographs, and I would strongly recommend this procedure.

Comments

The method of dividing pathology classes into small groups which, together with their tutors, circulate through special study rooms in which are concentrated specimens representing various diseases is recommended.

Pathology in America is taught with much more of a functional application than it is in this country. The importance of experimental pathology is stressed—in some cases perhaps too much, as students may occasionally think in terms of airy experimental theories rather than of the solid facts of morbid anatomy.

The micro-projector should be used much more in England, and, although one cannot teach detailed cytology by such methods, histological patterns of disease can be illustrated and be constantly put before the student of pathology as well as before clinical and postgraduate students. Pathology need not therefore be a watertight subject that too often is forgotten as soon as the pathology examination is past.

The American method of early specialization in pathology is open to criticism on the ground that students have had too brief a contact with the living patient (i.e., sometimes only two academic clinical years). In England the pathologist has had at least three full years' clinical experience before graduation, followed, very often, by a year or so of house jobs

The graded checking of the work of the trainee pathologist in the States is excellent, as is the early assumption of responsibility. The constant use of clinico-pathological conferences brings all aspects of medicine and surgery to the pathologist's notice, thus broadening his vision.

NEW POISONS RULES AMENDMENTS CONSOLIDATED

The Poisons Rules, 1949,* which were laid before Parliament on March 25, came into operation on April 11. This revision of the Poisons Rules (Statutory Instruments, 1949, No. 539) replaces the Poisons Rules of 1935 made under Section 23 of the Pharmacy and Poisons Act, 1933, and all the amendments to those rules which have been issued from time to time.

The Fourth Schedule again lists those substances required to be sold by retail "only upon a prescription given by a duly qualified medical practitioner, registered dentist, registered veterinary surgeon, or registered veterinary practitioner." Such substances will continue to be governed by the rule which lays down that a prescription shall:

(a) be in writing and be signed by the person giving it with his usual signature and be dated by him;

(b) except in the case of a health prescription, specify the address of the person giving it;

(c) specify the name and address of the person for whose treatment it is given or, if the prescription is given by a veterinary surgeon or practitioner, of the person to whom the medicine is to be delivered;

(d) have written thereon, if given by a dentist, the words "For dental treatment only" or, if given by a veterinary surgeon or practitioner, the words "For animal treatment only";

(e) indicate the total amount of the medicine to be supplied and, except in the case of a preparation which is to be used for external treatment only, the dose to be taken.

In an emergency an authorized seller of poisons may supply a doctor without a written order, say in response to a telephone request, if the practitioner gives an undertaking that such an order will be furnished within the next twenty-four hours.

The poisons listed in the Fourth Schedule are as follows:—

Allylisopropylacetylurea

Amidopyrine; its salts

Barbituric acid; its salts; derivatives of barbituric acid; their salts; compounds of barbituric acid, its salts, its derivatives, their salts, with any other substance

Dinitrocresols except agricultural or horticultural insecticides or fungicides; dinitronaphthols; dinitrophenols; dinitrothymols

6-morpholino-4 : 4-diphenylheptane-3-one; its salts

Para-aminobenzenesulphonamide; its salts; derivatives of para-aminobenzenesulphonamide having any of the hydrogen atoms of the para-amino group or of the sulphonamide group substituted by another radical; their salts, except when contained in ointments and surgical dressings

Phenylcinchoninic acid; salicyl-cinchoninic acid; their salts; their esters

Sulphonal; alkyl sulphonals

Tridione (3 : 5 : 5-trimethylloxazolidine-2 : 4-dione)

Most of these substances are better known to practitioners under trade or other names.

A prescription which comes under the Fourth Schedule must not be dispensed more than once unless the prescriber directs that it may be dispensed a stated number of times or at stated intervals. There must be noted on the prescription the name and address of the seller and the date on which the prescription was dispensed. The prescription must also be retained and kept on the premises for two years so that it is readily available for inspection. This last provision does not apply to a "health prescription," which is defined as a prescription given by a doctor or a dentist in accordance with the National Health Service Act, 1946, or the National Health Service (Scotland) Act, 1947, or given by a doctor or dentist upon a form issued by a local authority for use in connexion with the health services of that authority.

*Poisons: The Poisons Rules, 1949, H.M.S.O., price 9d.

AT THE FIRST GASP

Clinical experience has amply confirmed original reports on the value of 'Neo-Epinine' in the treatment of bronchial asthma. Equal to adrenaline and superior to ephedrine in anti-asthmatic activity, it is relatively free from the undesirable side-effects of both these drugs. 'Neo-Epinine' is administered simply, either sublingually or by oral inhalation, thereby avoiding the necessity for injection. Issued for sublingual administration as compressed products each containing 20 mgm., in bottles of 25 and 100; and as 1 per cent Spray Solution in bottles of 10 c.c.

'NEO-EPININE'

ISOPROPYL_{nor}ADRENALINE SULPHATE

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

Why these two aids in infant care receive medical support

In the treatment and care of infants in recent years efforts have been persistent to reduce the incidence of skin irritations such as impetigo and urine rash.

Nothing has contributed more towards meeting this problem than Johnson's Baby Lotion. Wherever it has been used in hospitals, clinics and welfare centres skin conditions improved.

Johnson's Baby Lotion is a homogenized emulsion of specially compounded mineral oil and water with lanolin. It is antiseptic and forms a protective discontinuous film that allows

the normal function of the skin.

Together with Johnson's Baby Powder, here are two indispensable aids in baby care, not only while under your personal supervision but when mothers care for their babies at home.

If you are not yet personally familiar with Johnson's Baby Lotion we will gladly send you samples.

BABY LOTION

For nappie-change to avoid irritations.

BABY POWDER

For after babies' baths.

MULTIS TERRIBILIS CAVETO MULTOS (AUSONIUS)

Those that are a cause of fear to many should themselves avoid crowds. In Rome, do as the Romans do. But in modern times crowds are as difficult to avoid as the virus of the common cold. 'Endrine' nasal compound provides a simple method of treating coryza and catarrh. It contains ephedrine which shrinks the engorged mucosa, whilst the oily base brings soothing relief to the inflamed membranes. Free breathing becomes possible and droplet infection is prevented.

ENDRINE

Nasal Compound

Formula: ephedrine 0.75% w/w; menthol 0.5% w/w; camphor 0.5% w/w; eucalyptol 0.5% w/w; oil of sumac 0.35% w/w; Light liq. paraffin q.s. to 100

'TRILENE'

A SAFE AND VALUABLE ANAESTHETIC

'Trilene' is now universally accepted as a safe and valuable anaesthetic for most operations. It can be used for induction or maintenance, or for maintenance with curare*. Notable advantages are the small quantities needed, the rapidity of recovery and the absence of vomiting and other unpleasant after-effects.

'Trilene' has also been used with great success to produce safe and reliable analgesia.

*An abstract of a report on these uses in over 40,000 cases is available.

Containers of 250 c.c., 500 c.c.

Crushable ampoules of 1 c.c., boxes of 5.

Ampoules of 6 c.c. in containers of 1, 5 and 25.

Literature and further information will be supplied on request from your nearest I.C.I. office: London, Bristol, Manchester, Glasgow, Edinburgh, Belfast and Birmingham.

Special Hospital Provisions

Medicines containing poisons which are supplied to patients in hospitals or in out-patient departments are subject to much the same rules. Where substances included in the First Schedule to the Rules are supplied a record must be kept for two years of the name and quantity of the poison supplied, the date on which it was supplied, the name and address of the patient, and the name of the person who supplied the poison or who gave the prescription for it. Again this rule does not apply to prescriptions given by doctors or dentists under the N.H.S. Acts. The containers of such medicines must be labelled with a designation or address sufficient to identify the hospital, or dispensary, or health centre issuing it.

Medicines containing poisons shall be supplied only for use in wards, operating theatres, or other departments on a written order signed by a doctor, or dentist, or "by a sister or nurse in charge of a ward, theatre, or other section of the institution." Again the container of the medicine must be labelled with words describing its contents and in the case of substances included in the First Schedule with a distinguishing mark indicating that it must be stored in a cupboard reserved solely for the storage of poisons.

Where poisons are stored on shelves in a dispensary or pharmaceutical department the container of the poison "must be rendered distinguishable by touch from the containers of articles other than poisons stored on the same premises." All places in which poisons are stored must be inspected at regular intervals, not exceeding three months, by a pharmacist or some other person appointed by the governing body or person in control of the institution.

First Schedule

Substances included in the Poisons List to which special restrictions apply are as follows:

Alkaloids, the following; their salts, simple or complex:
 Acetyldihydrocodeinone
 Aconite, alkaloids of, except substances containing less than 0.2 per cent of the alkaloids of aconite
 Apomorphine except substances containing less than 0.2% of apomorphine
 Atropine except substances containing less than 0.15% of atropine
 Belladonna, alkaloids of, except substances containing less than 0.15% of the alkaloids of belladonna calculated as hyoscyamine
 Benzoylmorphine
 Benzylmorphine
 Brucine except substances containing less than 0.2% of brucine
 Calabar bean, alkaloids of
 Coca, alkaloids of, except substances containing less than 0.1% of the alkaloids of coca
 Cocaine except substances containing less than 0.1% of cocaine
 Codeine except substances containing less than 1.5% of codeine
 Colchicine except substances containing less than 0.5% of colchicine
 Coniine except substances containing less than 0.1% of coniine
 Cotarnine except substances containing less than 0.2% of cotarnine
 Curare, alkaloids of; curare bases
 Diacetylmorphine
 Dihydrocodeinone
 Dihydrodesoxymorphine
 Dihydrodihydroxycodeinone
 Dihydromorphine
 Dihydromorphinone
 Ecgonine except substances containing less than 0.1% of ecgonine
 Emetine except substances containing less than 1% of emetine
 Ergot, alkaloids of
 Ethylmorphine except substances containing less than 0.2% of ethylmorphine
 Gelsemium, alkaloids of, except substances containing less than 0.1% of the alkaloids of gelsemium
 Homatropine except substances containing less than 0.15% of homatropine
 Hyoscine except substances containing less than 0.15% of hyoscine
 Hyoscyamine except substances containing less than 0.15% of hyoscyamine
 Jaborandi, alkaloids of, except substances containing less than 0.5% of the alkaloids of jaborandi
 Lobelia, alkaloids of, except substances containing less than 0.5% of the alkaloids of lobelia
 Morphine except substances containing less than 0.2% of morphine calculated as anhydrous morphine
 Nicotine
 Papaverine except substances containing less than 1% of papaverine

Pomegranate, alkaloids of, except substances containing less than 0.5% of the alkaloids of pomegranate
 Quebracho, alkaloids of
 Sabadilla, alkaloids of, except substances containing less than 1% of the alkaloids of sabadilla
 Solanaceous alkaloids, not otherwise included in this Schedule, except substances containing less than 0.15% of solanaceous alkaloids calculated as hyoscyamine
 Stavesacre, alkaloids of, except substances containing less than 0.2% of the alkaloids of stavesacre
 Strychnine except substances containing less than 0.2% of strychnine
 Thebaine except substances containing less than 1% of thebaine
 Veratrum, alkaloids of, except substances containing less than 1% of the alkaloids of veratrum
 Yohimba, alkaloids of
 Allylisopropylacetylurea
 Amidone (*dl*-2-dimethylamino-4 : 4-diphenyl-heptane-5-one); its salts
 Amidopyrine; its salts
 Amino-alcohols, esterified with benzoic acid, phenylacetic acid, phenylpropionic acid, cinnamic acid or the derivatives of these acids, except in substances containing less than 10% of esterified amino-alcohols
 Antimonial poisons except substances containing less than the equivalent of 1% of antimony trioxide
 Arsenical poisons except substances containing less than the equivalent of 0.01% of arsenic trioxide and except dentifrices containing less than 0.5% of acetarsol
 Barbituric acid; its salts; derivatives of barbituric acid; their salts; compounds of barbituric acid, its salts, its derivatives, their salts, with any other substance
 Barium, salts of
 Beta-aminopropylbenzene; its salts, its N-alkyl derivatives; their salts; beta aminoisopropylbenzene; its salts; its N-alkyl derivatives; their salts
 Cannabis; the resins of cannabis; extracts of cannabis; tinctures of cannabis; cannabin tannate
 Cantharidin except substances containing less than 0.01% of cantharidin
 • Cantharidates except substances containing less than the equivalent of 0.01% of cantharidine
 Carbachol
 Digitalis, glycosides and other active principles of, except substances containing less than one unit of activity (as defined in the *British Pharmacopoeia*) in two grammes of the substance
 Dinitroresols except agricultural and horticultural insecticides or fungicides; dinitronaphthols; dinitrophenols; dinitrothymols
 Ergot; extracts of ergot; tinctures of ergot
 Guanidines, the following: polymethylene diguanidines, dipara-anisyl-phenetyl guanidine
 Hydrocyanic acid except substances containing less than 0.15%, weight in weight, of hydrocyanic acid (HCN); cyanides except substances containing less than the equivalent of 0.1%, weight in weight, of hydrocyanic acid (HCN); double cyanides of mercury and zinc
 Lead, compounds of, with acids from fixed oils
 Mercuric chloride except substances containing less than 1% of mercuric chloride; mercuric iodide except substances containing less than 2% of mercuric iodide; nitrates of mercury except substances containing less than the equivalent of 3%, weight in weight, of mercury (Hg); potassio-mercuric iodides except substances containing less than the equivalent of 1% of mercuric iodide; organic compounds of mercury except substances containing less than the equivalent of 0.2%, weight in weight, of mercury (Hg)
 Metanitrophenol; orthonitrophenol; paranitrophenol
 Metopon (methylidihydromorphinone); its salts
 6-morpholino-4 : 4-diphenylheptane-3-one; its salts
 Nux vomica except substances containing less than 0.2% of strychnine
 Opium except substances containing less than 0.2% of morphine calculated as anhydrous morphine
 Ouabain
 Oxycinchoninic acid, derivatives of; their salts; their esters
 Para-aminobenzenesulphonamide; its salts; derivatives of para-aminobenzenesulphonamide having any of the hydrogen atoms of the para-amino group or of the sulphonamide group substituted by another radical; their salts
 Pethidine; its salts
 Phenetidylphenacetin
 Phenylcinchoninic acid; salicylcinchoninic acid; their salts; their esters
 Phenylethylhydantoin; its salts; its acyl derivatives; their salts
 Picrotoxin
 Savin, oil of
 Sodium, monofluoracetate
 Strophanthus, glycosides of
 Sulphonal; alkyl sulphonals
 Thallium; salts of

Tribromethyl alcohol
Tridione (3 : 5 : 5-trimethyloxazolidine-2 : 4-dione)
Zinc phosphide

In the Third Schedule of the Poisons Rules there are listed articles exempted from the provisions of the Pharmacy and Poisons Act and of the Rules. These include, for example, extracts and tinctures of ipecacuanha and substances containing less than 0.05% of emetine; substances containing less than 10% of chloroform; and ointments containing less than 3% weight for weight, of mercury.

The other schedules follow the pattern laid down in the twelve schedules of the 1935 Poisons Rules. An additional four schedules are concerned with such things as the purchase of strychnine for killing seals and the colouring of some compounds of arsenic.

MISSIONARY ENDEAVOUR

C.M.S. Celebrations

The Church Missionary Society celebrated on April 12 its 150th anniversary. It was founded in an Aldersgate Street tavern in 1799 by a group of 16 clergy and 9 laymen with whom William Wilberforce and Zachary Macaulay were associated, though they were not present at that first meeting. The first interest of the Society was in Africa, and a few years later it entered India and Ceylon. Work in China was undertaken in the 'forties of the last century, and in Japan and Persia some thirty years later. The Society is now responsible for more than half the missionary force of the Church of England and for about a quarter of the total missionary work of British societies. It has nearly one thousand missionaries on its register, about two-thirds of whom are women.

The first medical missions under the Society's auspices were not inaugurated until 1865. Doctors had been sent abroad by the Society from 1840 onwards, but not as missionaries; their work was to care only for the health of the missionaries proper. The first C.M.S. medical mission was started in the native state of Kashmir. The next was at Hangchow in 1871. In the ten years from 1880 to 1890, hospitals were opened in Persia, Palestine, India, and Egypt. A C.M.S. hospital was established in 1897 at Mengo in Uganda Protectorate. A full account of the work done there under the direction of Mr Albert Cook appeared in these columns on the occasion of the Mengo Hospitals Jubilee (Aug. 30, 1947, p. 342). The

I.S., which is responsible for half the medical work of Anglican missions, now has 51 hospitals and 149 dispensaries. More than five million treatments are given each year, and in every hour of the day more than 500 patients receive some form of treatment through C.M.S. hospitals, out-stations, welfare centres, and clinics.

The burden of rising costs affects missionary societies as much as other institutions. It is not only at home that money values have altered. In China it now costs as much to put in the windows of a rebuilt hospital as it cost to build the entire hospital before the war. In East Africa nurses' uniforms cost twice as much as they did, and the cost of medicines has gone up sixfold. In India the maintenance cost of a hospital bed has trebled.

The number of European-trained nurses working for the Society is 105. It was mentioned at a Press conference at the Society's headquarters in Salisbury Square that about 80% of the nurses at work in India are Christians. Many of them have been trained at C.M.S. hospitals. The Indian-trained nurse is almost always the product of Christian example and missionary organization. As for medical men and women, stress was laid at the conference on the fact that for missionary work, especially in certain regions and certain types of service, such as that among lepers, a sense of vocation is needed. Some sense of vocation is called for, of course, in all medical work, but it is especially important in Christian missions, among people alien in thought and custom and in a strange environment. In many lands the Church Missionary Society has led the way to State action in organizing medical services. Now that Government-provided medical services are increasingly widespread in Africa and the East, the aim of the Society's

medical missions is changing to the extent that instead of providing centres which specialize in a particular type of medical work it aims at a general healing ministry, integrated with the Society's main evangelical and educational programme. The need for medical services in the lands which the Society occupies remains, of course, overwhelming. In India there is one doctor for every 10,000 people. China, with ten times as many people as there are in the British Isles, has fewer doctors than there are in London.

AMERICAN REVIEW OF SOVIET MEDICINE

The October, 1948, issue of the *American Review of Soviet Medicine*, recently received, contains the announcement that the publication is to be suspended indefinitely. The Review first appeared in October, 1943, sponsored by the American-Soviet Medical Society, under the presidency of the late W. B. Cannon. It was designed to publish translations of important papers from Russian medical literature, survey articles of various aspects of Russian medicine by American experts, news of current medical events in the U.S.S.R., reviews of Soviet medical books, etc. Edited throughout its existence by Dr. Henry E. Sigerist, the Review made possible a wide exchange of medical information between the Soviet Union and the English-speaking countries, while the American-Soviet Medical Society was able to build up an extensive library of Russian literature. In a valedictory editorial Dr. Sigerist writes: "Much to our regret we are unable to [continue publication] for reasons which are so obvious that we need not elaborate on them." As the difficulty in obtaining medical literature from the U.S.S.R. has not appreciably increased since 1943, other factors must be responsible for the decision to discontinue the Review. The American-Soviet Medical Society is to continue in being, and will keep its members informed of medical developments in the U.S.S.R. by issuing mimeographed reports whenever there is an opportunity.

TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council invites applications for the following Travelling Fellowships for the academic year 1949-50.

Rockefeller Medical Fellowships

These fellowships are provided from a fund with which the Council has been entrusted by the Rockefeller Foundation of New York. They are intended for graduates resident in this country who have had some training in research work in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in the United Kingdom. The stipend will ordinarily be at the rate of £650 per annum for a single Fellow, and of £900 per annum for a married Fellow. Travelling expenses and some other allowances will be paid in addition.

Dorothy Temple Cross Research Fellowships in Tuberculosis

These fellowships are awarded by the Council from a special endowment of which it is the trustee. The object of the fellowships, as defined in the trust deed, is to give special opportunities for study or research to suitably qualified British subjects of either sex "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." The fellowships will, as a rule, be awarded to candidates who wish to make their studies or inquiries elsewhere than in the United Kingdom. They will ordinarily be awarded for one academic year. The fellowships provide for the payment of stipend, together with an allowance for travelling and incidental expenses. The stipend will ordinarily be at the rate of £650 per annum for a single Fellow, and of £900 per annum for a married Fellow.

Completed applications for fellowships of either type must be lodged with the Council by June 1. Further particulars and forms of application are obtainable from the Secretary, Medical Research Council, 38, Old Queen Street, Westminster, London, S.W.1.

Reports of Societies

REORIENTATIONS IN NEUROLOGY

At a meeting of the Manchester Medical Society on Feb. 2 Sir CHARLES SYMONDS delivered an address on this subject.

He said that the most fascinating and elusive problem of neurology was that of the selective lesion. This or that structure was picked out again and again by different diseases so that, for example, examination of the pupils alone might warrant the diagnosis of neurosyphilis. Of the reasons for this hardly anything was known, but it might depend partly upon the effect of toxins, or upon deficiencies in specific biochemical functions. Myasthenia gravis was the best-known example of a biochemical lesion; familial periodic paralysis and porphyria were less well understood, but of interest because of the genetic factor. Some of the obscure paralyses, such as that described by Landry, might be caused similarly. The paralysis of botulism and the spasm of tetanus were now known to depend upon derangement of the acetylcholine-cholinesterase mechanism of neuromuscular transmission. There was evidence suggesting that this mode of transmission might also exist within the central nervous system across synapses, and, if so, certain functional nervous disorders might prove to be caused by analogous biochemical disturbances.

Specific patterns of central nervous disease were related to equally specific nutritional deficiencies. Subacute combined degeneration of the cord was one familiar clinical example, and the prison camps in the Far East had provided others. Animal experiments had shown correlation between the histological pattern of lesions and specific vitamin deficiencies, whether due to lack of vitamins or excess of anti-vitamins in the diet. Disseminated sclerosis remained a mystery, but the experimental production by Weston Hurst of demyelination of optic nerves and other structures in the monkey by interference with intracellular oxidation suggested the possibility of a biochemical lesion.

Bodian and Howe had shown that the susceptibility of anterior horn cells to the virus of poliomyelitis could be modified by an artificially induced resting state following section of peripheral nerves. Bodian had further demonstrated that the natural immunity of rhesus monkeys to oral infection by the virus of poliomyelitis was lost when the animal was deprived of pyridoxine. It seemed, therefore, that we might have to think in terms of interaction between virus and metabolic disorder if we were to understand the aetiology of certain nervous diseases.

CHELSEA CLINICAL SOCIETY

The sixth meeting of the session was held on March 8 at the South Kensington Hotel, with the president, Mr. NILS ECKHOFF, in the chair. A discussion on prefrontal leucotomy was opened by Mr. W. McKISSECK, who himself had operated on over one thousand cases, and was continued by Dr. CURRAN, whose experience of investigation and aftercare was equally extensive. An interesting discussion ensued in which Drs. BRUNTON BLAICKIE, GUY BEAUCHAMP, FURBER, BUCKLEY SHARP, SKENE KEITH, WAYNE ROE, MOODY, GORSKY, and Mr. CRUMBIE and Mr. GUERRIER took part. Members were asked to take note of the annual dinner date, which was fixed for Tuesday, May 10.

At the third meeting of the Administrative and Clerical Staffs Whitley Council on Feb. 1 it was agreed that the London "weighting" for administrative and clerical officers aged 26 years and over with salaries of under £760 a year should be £30 a year in all sections of the National Health Service. It should now be paid as from Feb. 1 to all such officers employed in the Metropolitan Police area who have not already received it. Agreement was reached on the salaries of senior officers of hospital management committees and boards of management. The salaries are based on a new system by which a varying number of points are allotted to hospitals and institutions of different sizes. The salaries for secretaries vary from £640 by £25 to £890 to £1,400 by £50 to £1,700, and for deputy secretaries from £430 by £15 to £595 to £935 by £30 to £995 by £35 to £1,135. The scales are subject to the addition of London weighting, and they operate as from Jan. 1.

Correspondence

Transmission of Sarcoma by Dried Tissue

SIR,—Professor W. E. Gye (March 26, p. 511) describes a method of extracting a very powerful carcinogen from three sarcomas of mice after a treatment of the tumours by freezing and desiccation which is thought to exclude the survival of any cells. All cancer research workers will congratulate him and his associates on this achievement, and those who have worked with the weaker carcinogens, which take effect chiefly in the second year, will be impressed by the prospect of results obtainable in 2 to 4 weeks after injection.

The results described show undoubtedly that, if the death of all cells can be assured, a very active carcinogen has been obtained from mouse sarcomas. Professor Gye concludes that this particular carcinogen differs from many others in being also the cause of the continued growth of tumours. Do the experiments, in their present state, necessarily bear this interpretation? The proof of the identity of these two agents does not seem to me quite clear.

As one who was concerned, chiefly on the administrative side, with the pioneer work of Mayneord, Hieger, Cook, and Hewett on carcinogenic compounds, I am very glad that methylicholanthrene has performed the humble, and essential, part of initiating the growth of one of the tumours used by Gye, and I am sure that Professor J. W. Cook, to whom we owe the existence of this compound, would agree.

The distinction between the initial and the continuing cause of cancer suggests many attractive speculations. For instance, one would like to know what was the first abnormal change in the fowl which produced the Chicken Sarcoma I of Murphy and Rous. What determines whether a wild cottontail rabbit does or does not develop a Shope tumour? Why is sarcoma a very rare spontaneous tumour in the mouse, the species in which this new agent has been discovered? Why are certain compounds carcinogenic or, as one might say, able to liberate a virus, while other closely allied compounds have not this power?

One hopes that Professor Gye and his staff will go on to test filtrates of these tumours. Dr. L. D. Parsons has recorded the production of sarcomas by filtrates of sarcomas of the mouse induced, as was one of the three used by Gye, by a hydrocarbon (a derivative of 1:2:5:6-dibenzanthracene). Preliminary statements of her work, which was interrupted, were given in the 12th to the 17th Annual Reports of the British Empire Cancer Campaign and elsewhere.^{1,2}

In the same issue of the *British Medical Journal* the author of a leading article (p. 531) states, "Suppose . . . we can safely accept the conclusion that tumours in general can be propagated in the absence of viable tumour cells, where does this lead? . . . It means that of current theories of the nature of cancer some 90% can be quietly relegated to the waste-paper basket. . . ." It would be interesting to know what are, say, nine of these theories which are demolished by experiments upon some sarcomas of the mouse.

Those of us who have reached "cancer age," and are hoping to avoid cancer altogether, are naturally more interested in the initial cause of cancer than in the continuing cause. The results described by Professor Gye should assist discrimination between these two effects.—I am, etc.,

St. Bartholomew's Hospital,
London, E.C.1.

The Lethal Danger of Desoxycortone Overdosage

SIR,—Although I have written fully on this subject in Price's *Practice of Medicine*, Hutchison's *Index of Treatment*, *Major Endocrine Disorders*, etc., I have met with three cases in undergraduate and postgraduate centres in the last few months and feel called upon to make a further note.

Desoxycortone is used in Addison's disease and Simmonds's disease because it is an easily administered essential hormone of the adrenal cortex, affecting salt and water metabolism but not carbohydrate metabolism. Overdosage results in excessive

retention of salt and water and excessive excretion of potassium, with resulting low serum potassium values. There may be obvious oedema of superficial tissues, with or without hypertension; or more insidious pulmonary oedema, going on to general anasarca; or the paralytic effects of low potassium concentrations may be presenting features. (I do not include the occasional production of more chronic hypertension without any fluid retention or depression of potassium.) With injection treatment, an awareness of the possibility of overdosage permits its avoidance or easy correction by diminishing or withdrawing the desoxycortone injections. However, the facility of and patients' preference for subcutaneous implantation of tablets has led to the increasing use of this method, and here the only really reliable method of counteracting overdosage through wrong calculation is by removal of some or all of the tablets—a procedure which is not as easy as their implantation. Temporary corrective measures are the use of diuretics—e.g., mersalyl, urea; and potassium citrate by mouth if the serum potassium is known to be low.

In December, 1938, I made the first report on Addison's disease (four cases) treated with implantations of desoxycortone acetate.¹ The dose I chose, rather empirically, was 200 mg. for the initial implantation. Although my subsequent arithmetical formula was rather higher—one 100 mg. tablet for each 1 mg. of desoxycortone injected daily, giving an implantation of some 400 mg. for the average case—I am tending to return to 200 mg. as an initial implantation. Thorn and his colleagues^{2,3} suggested the rather high equivalent of 100 mg. for each 0.5 mg. of desoxycortone injected daily. The use of this high equivalent has undoubtedly led to overdosage by the implantation method in other clinics, although Thorn is careful to point out that the maintenance dose after several weeks or more is less than the initial maintenance dose. Even so, this equivalent is, I believe, still too high, and for initial implantation probably twice as high as is prudent over a series of cases.

In a recent case of overdosage two separate implantations of 200 mg. each at intervals of seven months were successful, whereas a third of 300 mg. led to oedema and depression of serum potassium. Some patients, in the case of both Addison's and Simmonds's disease, are particularly sensitive to desoxycortone, and this sensitivity may vary. Certainly no patient should have an initial implantation of desoxycortone before a trial period of several weeks with desoxycortone injections. The patients who have their mineral metabolism well balanced (as judged by chemical estimation) by desoxycortone implantations nevertheless may be liable to chronic hypoglycaemia, with hypoglycaemic exacerbations which may prove fatal, and this should be looked for and anticipated. It should also be remembered that cortical extract (e.g., "eucortone," "eschatin"), although much safer than desoxycortone from the point of view of excessive salt and water retention, can in large doses produce or aggravate it. A further point is that if testosterone is implanted as supplementary therapy with the desoxycortone the dose of the latter must be less, as testosterone has a salt and water retaining effect and may tip the scales in the wrong direction. Of course, supplementary salt by mouth is another aggravating or reinforcing factor when the dose of desoxycortone is on the high side.

The justification for this letter is the not infrequent occurrence of overdosage effects from desoxycortone—grave or even lethal—some ten years after initial experience with this valuable and highly potent form of therapy.—I am, etc.,

London, W.1

Statistics and Health Education

SIR.—You report (*Supplement*, March 26, p. 160) that the Ministry of National Insurance is about to collect some more statistics (about illness) and that the public health department of the Middlesex County Council has been holding a discussion on the strategy of health education (March 26, p. 538). Now presumably the objects of both these activities are the same—to improve the health of the people—but are either of them using

the best approach? The Ministry, according to your leading article (p. 533), is asking, "How often are we ill?" (Without a single extra page of statistics, do we not already know the answer? Too often.) It is, however, also collecting much information about age groups, marital status, etc., and it says that the validity of the statistics will depend on the accuracy of the diagnosis as stated on the certificate. In other words, it must be able to classify the "diseases" from which patients are suffering.

Now, Sir, if we want to get the right answer we must ask the right questions. If we want to keep people well, then surely the right question to ask is, "Why do they get ill?" and not, "What illness have they got?" After all, it is human beings who get ill, and disease is a metaphysical conception. What help is it to us to say precisely what illness the patient is suffering from if we do not know why he got ill? We have not finished when we have stuck a so-called diagnostic label on the patient—we are just at the beginning.

You have given the Middlesex discussion the subtitle "Telling the Public." Would not a better approach to the problem be "Asking the Public"? As Dr. Hill said, too little is known about the prevention of disease. Would it not be better to ask the patients about the circumstances which led to their illness rather than concentrating exclusively on the precise nature of that illness? If we did, is it not likely that we should learn something more about prevention? The Ministry presumably wants to find out something about why married women get ill so frequently. Why doesn't it ask my coalman? In his office he has a notice: "The wife works seven days a week—I work five." Suppose the Ministry were to ponder for a time on that notice and then ask itself, "Are our statistics really useful?" On the other hand, if Dr. Hartston did start "calling all lumbagos" (and got a reply from all neurotics) would he really be so sure exactly what to tell them to do to prevent further attacks? And would they really want to do it?

There is another question which has always intrigued me: In an epidemic of influenza, why does not everyone catch it? Do we know the answer, and would it not help us if we did? The trouble as I see it, Sir, is that only those of us have time to think who are removed from reality—that is, from general practice. (As the train bears me away to rural Sussex I can cogitate over the articles in your *Journal* in a way that was impossible when I was tearing back to do a surgery in south-west London.) The consequence is that attempts at preventive medicine are being made in a sort of vacuum—hence their ill-success.

An intelligent community that really wished to improve its health would put its best doctors into general practice and give them sufficient leisure to research into the problems of real life. It is doubtful whether we are an intelligent community, but is not this an opportunity for somebody—perhaps the Rockefeller Foundation—to subsidize a few selected general practitioners to do some research? We might then get some useful results.—I am, etc.,

East Hoathly, Sussex.

F. GRAY.

Hyperinsulinism Due to Islet-cell Adenoma

SIR.—As a mere student, I hesitate to trespass on the pages of the *Journal*. However, I feel it only just to point out that the historical summary prefacing Dr. W. G. Duncan Murray's article (March 26, p. 521) on islet-cell adenoma is not quite accurate in one respect. Dr. Murray states that the first operative cure for this condition was reported by Carr and his colleagues in 1931.¹ It is generally acknowledged in the literature that the first operative cure preceded this by two years, being reported by Howland, Campbell, Malby, and Robinson in 1929.² This case was reviewed, together with three others, in 1939 by Campbell, Graham, and Robinson,³ the patient being alive and well after ten years. Carr and his colleagues do in fact acknowledge this precedence in the preamble to their original paper. I hope this gentle reminder will not be taken for quibbling. It is rather important that this case should be remembered, as the follow-up is the longest recorded.—I am, etc.,

Manchester, 15.

Delayed Admission to Hospital

SIR,—In your leading article (March 26, p. 532) two instances were given illustrating the difficulty which at present exists in gaining immediate admission for even acute surgical emergencies to hospital. But the circumstances differed considerably in the two cases you quoted.

The first, that of a patient with tuberculosis who developed a superimposed and presumably non-tubercular condition, belongs to a problem group which most certainly existed long before the appointed day. In the past there was the same difficulty in accommodating the acute case who in addition had open tuberculosis. Sanatoria, if perchance there was a vacant bed, often had no facilities for operative treatment. General hospitals, on the other hand, were loath to admit cases of open tuberculosis to their wards, and some hospitals had a regulation that such cases should not be admitted. The solution to this problem would be to reserve in each area a number of beds, and a very small number would suffice, at one hospital where facilities exist both for emergency (i.e., operative) treatment and for isolation of the patient.

The second case you described revealed an even more serious state of affairs. As stated later in your article, "... before July, 1948, any hospital, however hard-pressed, always managed to find room for someone in need of life-saving medical or surgical treatment." I cannot believe that the refusal of such emergencies is a common occurrence throughout the country. Certainly in the smaller towns with one, or at the most two, general hospitals the difficulty of gaining admission would not often arise. In such towns, even since July, 1948, the "individual" responsibility of the hospitals continues—it must, for there is no alternative.

The "group principle" will lead to a measure of better co-ordination between hospitals in some ways, but at the same time it inevitably weakens the sense of "individual responsibility," which now becomes diffused into "group responsibility." In view of the difficulties which the Emergency Bed Service is experiencing it might be wise to reconsider the proposed bed bureau in other regions.

Your article concluded by stressing the urgent need for the "quick re-establishment of authority to secure the immediate admission into a State hospital of an acutely ill person," but did not suggest who would wield such authority. Earlier you referred to the authority of the relieving officer under the Poor Law and Local Government Act. Surely it is not proposed that a similar authority should be re-established? Moreover, it was seldom that the relieving officer had to deal with the acute emergency; rather he requested admission for aged or chronically ill patients, and on grounds more often social than medical or surgical.

This raises yet another problem, and one which is common in all regions, the difficulty of providing sufficient accommodation for the aged requiring hospital treatment. A large percentage of the cases in the old poor law institutions which have now been taken over as State hospitals are ambulant and no longer in need of hospital treatment. If these cases could be found accommodation outside the hospitals, much-needed beds would immediately be available for the aged who require and are waiting for treatment. It almost seems that the authority to admit should in this instance be reversed to "the authority to discharge."

Local authorities have now been given the task of providing accommodation for the aged in need of care and attention. But, bereft of their institutions, hampered by covenants and restrictions in their efforts to convert existing large houses, and apparently without priority to build hostels, they have an unenviable task. Certainly it will take several years to provide the much-needed hostel accommodation. Until it is provided the waiting-lists of the aged and chronic sick will continue. The re-establishment of authority will not solve this problem.

—I am, etc.,

Nottingham

WILLIAM MORTON.

SIR,—If only to stress the importance of your leading article (March 26, p. 532) I wish to record a recent experience. While acting as locum to a doctor in X, I recently saw on a Saturday morning a boy aged 3 years—in his third week of whooping-cough—suffering from acute appendicitis. I rang up Hospital

A, who stated that they had no accommodation for a case of infectious disease and referred me to Hospital B, where there are cubicles. On requesting the child's admission, I was told that there was no bed. On my inquiring for the emergency bed service I was informed that no official was present—it then being after 12 noon. I then tried Hospital C, where I again drew a blank. Finally I telephoned Hospital B again, and it was not until I suggested ringing up the Ministry of Health that a bed was found.

The child was operated on the same afternoon and the appendix was found to be gangrenous. The patient is now at home convalescing. Had I not persisted in my demand for a bed I have little doubt that the boy would have died. An emergency service that does not function between noon on Saturday and 9 a.m. on Monday is a farce.—I am, etc.,

M. B. REICHWALD.

Diagnosis of Early Pulmonary Tuberculosis

SIR,—Many experienced general practitioners will agree with Dr. Reginald Fisher (April 2, p. 591) that the selection of patients to be referred to the local tuberculosis officer is no easy matter, and there can be no doubt that the great majority of tuberculosis clinics have neither the staff nor the other facilities for dealing with all those who should be referred to them.

It was in order to meet this difficulty that in January, 1948, a miniature radiography unit was installed at the Cardiff tuberculosis clinic, to which practitioners were invited to send any patient with symptoms of ill-health, not necessarily suggestive of pulmonary tuberculosis. Those with more definite symptoms were referred to the clinic in the usual way. This scheme has proved a success in Cardiff and has led to the discovery of a considerable number of early cases of tuberculosis as well as other chest diseases.—I am, etc.,

Cardiff.

S. H. GRAHAM.

The Thymus in Meningococcal Septicaemia

SIR,—I think that Drs. Peter Turner and R. V. Dent (March 26, p. 524) will allow me to comment on the fleshy thymus glands which were found in their two post-mortem cases of meningococcal septicaemia. I am sure that it is a misinterpretation which leads them to state that "the rapid course of the illness makes it evident that the (thymic) enlargement preceded infection." On the contrary, the rapid course of the illness did not give the thymus gland time to undergo the gross involution which occurs during the course of any serious illness lasting more than a few days.

In Case 3, a girl of 15, the thymus, which is considered to be enlarged, weighed 42 g. This is well within the range of 13 to 50 g. given by Boyd¹ for the age group 10–15 years. The latter figures are based on forty cases within this age group in which death, resulting from violence, occurred within twenty-four hours. Histologically the thymus glands in Cases 1 and 3 appeared normal, and, in view of what I believe to be normal weights also, I see no evidence to suggest that the thymus plays any part in meningococcal septicaemia. In conclusion, may I quote from Boyd's paper a sentence which sums up the position admirably: "Since most subjects who come to autopsy have been ill for more than three days, the pathologist's eye becomes adjusted to the involuted thymuses, so that the prominent thymus of the healthy, well-nourished subject appears enlarged to him."—I am, etc.,

London, S.E.5.

Cough Fracture in Pregnancy

SIR,—In the light of the interest stimulated by the recent report of four cases by Drs. J. W. Paulley, D. H. Lees, and A. C. Pearson (Jan. 22, p. 135), the following case may be of interest.

A woman of 36, who had been delivered of her third child three days previously, was seen at home on April 29, 1948. She gave a history of recurrent bronchial attacks during the preceding two years. One week before confinement she developed a severe cough, and three days later a sharp pain of pleuritic type in the left chest, and a little fever. Her side was strapped, and the confinement

proceeded normally. I was asked to see her, in view of the possibility of a tuberculous infection and its immediate danger to the infant. On examination, she was afebrile and did not appear ill. Her chest contained a number of bronchial signs; she had relatively weak air entry on the left, and was rather tender over the left base, with the most sensitive spot below the left scapula.

A small portable x-ray machine was taken out to her cottage, which was fortunately supplied with electricity. The film was considered normal and the case proceeded favourably, although the pain persisted in the left chest for some time. A check-up x ray was done three months later, which showed callus formation on the left 7th and 8th ribs in the posterior axillary line. Reinspection of the original film showed a suspicious line at the site of the lesion in the 8th rib, and there seems no doubt that the onset of the original "pleurisy" was in fact occurrence of the fractures.

This case shows the features mentioned by Drs. Paulley, Lees, and Pearson—a chronic cough in late pregnancy causing a fracture of the lower ribs on the left. It also suggests that such cases may be missed by a routine chest radiograph, which does not readily demonstrate a recent fracture without displacement.

My thanks are due to Dr. I. Speedy Bertin for the clinical features, and to Mr. A. F. Keith for the radiography in difficult circumstances.—I am, etc.,

Exeter,

G. E. ADKINS.

What is Normal?

SIR,—One of the early tasks of Dr. Clifford Allen's institute of psychosexual diseases (March 26, p. 547) should be the study of normal sexual behaviour. Kinsey has shown how ignorant we are of the conduct of normal people, and surely more work is needed along these lines, especially in this country, before we can really decide what is abnormal. For example, one might have been inclined to call homosexuality abnormal, but if Kinsey's statement that 37% of all American males have homosexual experience after adolescence (and more before) is true, that is hardly possible.

Having obtained a clearer idea of what is sex abnormality, one can then decide more rationally what should be regarded as sex delinquency, for abnormality and delinquency are quite distinct (homosexuality is probably not abnormal but certainly is illegal). The report of the joint committee of the B.M.A. and the Magistrates' Association (Supplement, March 12, p. 135) recommends an inquiry into the advisability of altering the law to allow homosexual conduct between consenting adults. But your comment (March 12, p. 446) that this and other proposals are "highly controversial," and that "many may think that any legal alterations which allow the actual or potential offender to think that law and order are weakening in his favour is inappropriate at a time when crime in general is becoming a grave menace to social security," is a little surprising. Surely homosexuality can hardly be regarded, along with, say, housebreaking, as a grave menace to social security? It is just such a comment as yours that makes one feel that it is so important to withdraw the term "criminal" from conduct which is essentially normal, and to restrict it to behaviour which involves another unwilling or under-age person.—I am, etc.,

London, S.W.4.

DAVID PYKE.

Health Regulations for Air Travel

SIR,—I have to draw your attention to the article by Air Commodore J. Kyle (Dec. 25, 1948, p. 1115), which tabulates a list of requirements for travellers from England to places on the routes operated by the British Overseas Airways Corporation.

For passengers from Southampton to Hong Kong it is erroneously stated in the table referred to above that cholera and plague inoculation certificates are required. For your guidance I must add that in so far as Hong Kong is concerned cholera inoculation certificates are only required from passengers who originate or pass through ports declared infected with cholera by Hong Kong.

In so far as plague is concerned your attention is also invited to the World Health Organization weekly fasciculus (1948, 21, No. 15, p. 219), which contains the following passage: "The following information was received from the port health officer, Hong Kong, on April 2, 1948. (1) Ships

and aircraft from ports declared infected against plague are subject to the following measures: Medical inspection, deraization of vessel or aircraft before and/or after discharge of cargo, if considered necessary after inspection of vessel or craft and its cargo. (2) Passengers from plague-infected ports are not required to produce inoculation certificates against plague."

I am therefore to request that you will be so good as to make this known to all concerned. I should add for your information that the local offices of all airlines operating from the United Kingdom to Hong Kong have been so informed.—I am, etc.,

I. NEWTON.

Director of Medical Services.

Hong Kong.

**Air Commodore Kyle gives us the following information: An aircraft lands at airports in six or eight countries en route to the Far East, and if only one of these countries enforces quarantine restrictions all travellers going beyond the airport in that country must produce a certificate of inoculation either on the way out or on the way back. Air passengers to Hong Kong pass through Augusta, Alexandria, Bahrain, Karachi, Calcutta, Rangoon, and Bangkok. Of the two diseases referred to by Dr. Newton a certificate of inoculation against cholera is required at Bangkok from passengers who have passed through Calcutta and Rangoon on the outward journey and a certificate of inoculation against plague is required on the homeward journey at Alexandria for passengers who have come from or passed through Bangkok.—ED., B.M.J.

Vesico-vaginal Fistula

SIR,—As none of your readers have responded to the invitation of Dr. D. T. R. Evans (March 12, p. 455) for information regarding the demonstration of the site of vesico-vaginal fistula by the injection of air, may I recount my experience in connexion with a similar problem.

About the year 1903, when I was trying to make myself familiar with the use of the cystoscope, I set out to demonstrate the site of a vesico-intestinal fistula. I imagined that this could easily be done by injecting coloured fluid into the rectum and observing it flowing through the fistula into the bladder, but soon found that this was fallacious and that the necessary information could not be obtained by this means.

During the examination air was unintentionally pumped into the rectum from an empty Higginson's syringe and at once found its way through the fistula and bubbled into the solution in the bladder, disclosing the site of the fistula and proving a most satisfactory method of localization. Since that time I have every now and again employed the method and can recommend it as being simple and valuable.—I am, etc.,

Taplow, Bucks.

G. GREY TURNER.

Observation of Children's Hearts

SIR,—I was glad to read Dr. R. Kembell Price's study (March 26, p. 515) of 200 cases of heart disease in children, started in his cardiac clinic 18 months ago. Each case was examined clinically and by electrocardiogram and by cardiocopy, so that five cases occupied an afternoon. This is excellent as a research method, but in 1941 I advocated a long-term plan by which in each routine school medical examination the heart angle was measured in every child. This can be done in two minutes, as only a tape measure is needed. The angle should remain constant throughout school life; if not, the cause of its increase must be sought (for prophylaxis) in valvular defect, rheumatic or other infections, athletic strain, or emotional stress. Unfortunately, in wartime none of the heart angles in my paper could be measured again in the following years; a long-term series is badly wanted.

If the apex beat moves outwards the heart is enlarged or distressed, but this linear distance increases as the child grows. Hence I measured it as an angle which does not change with growth. The simple method is to call the mid-sternum 0° and the mid-axilla 90° (one-quarter of the chest girth). In health the heart angle, measured from the left margin of the apex beat, should not exceed 45° in a child or adult. For instance, if the chest girth is 36 in. (90 cm.) the mid-axilla is 36 ÷ 4 = 9°, and the apex beat should not be more than 4.5 in

11.25 cm.)—i.e., 45°—from the midline. Thus the heart angle is the apex beat distance divided by the mid-axilla distance multiplied by 90°. Calculations can be saved by the chart in my paper, or by better ones obtained at H. K. Lewis and Co., 3ower Street, London, W.C.1. or I can send my reprints.

An enlarged heart angle is a clinical abnormality with a cause which demands treatment. It may or may not indicate an enlarged heart. Thus in effort syndrome I have always found the angle increased, but a telerradiograph shows no enlargement. This instructive discrepancy is mysterious, but Darwin long ago remarked that "in fear the heart knocks against the ribs"—owing to its emotional, slapping overaction.

I earnestly hope that doctors who examine children regularly, especially in boarding schools, will keep long-term records of the heart angle both in sickness and in health. I am confident that the results will be rewarding at the time and specially valuable when published after two or three years. Clinical reports are always far more instructive when the fourth dimension (time) completes them—as in my paper and as Dr. Price plans to do in greater detail.—I am, etc.,

Beverley, Yorks.

F. C. EVE.

Nurses and Nursing Aides

SIR,—It is quite clear that if the sick are to be nursed in hospital this cannot be done by a limited number of highly trained persons, however devoted and competent they may be. The opportunities open to academically gifted young women, especially in teaching and the social services, are now so numerous that we can no longer expect to obtain anything like an adequate number of them for nursing. We must therefore adopt measures on the lines suggested in the paper of Dr. E. B. Brooke and Mr. J. P. Wetenhall (March 19, p. 491): nor do I think that the profession of nursing will in any way suffer from this, but it will, I believe, gain increased recognition and prestige.

It is essential, however, that the ancillary worker—nursing aide or whatever her designation may be—shall be given a status and dignity in accordance with the important social duties she is carrying out. She must, as your contributors state, be in alignment with the ward nursing team. She must not come to be regarded as a nurse's menial or orderly. The rough-and-ready suggested division of nurses' duties between those ministering to the patients' comfort and those assisting the doctor is not sufficient for this purpose, nor, I imagine, was this intended.

We are at present considering the problem of "breaking down" nursing duties, much as has been done for many industrial processes; and we hope, with the guidance of experts in such problems, to be able to reach such a division as will leave with the ancillary worker such real nursing duties as will enable her to be emotionally satisfied and not frustrated by prohibitions (this is a vital matter), and also to make her help of value to the fully trained nurses, so that the two groups can work in the wards alongside each other, respecting and respected.

There will, of course, be difficulties in doing this, but it is to be hoped that the nursing authorities will recognize the urgent need for some such scheme and will make no difficulties about supporting it on the supposition that the status of the trained nurse will suffer. It will, in fact, be enhanced, and the sick will have some chance of being "nursed" in hospital instead of, as is too often the case at present, being "attended to as far as possible" at home.—I am, etc.,

St. Albans.

W. J. T. KIMBER.

Taking Children's Temperatures

SIR,—May I round off this topic with a few comments? Some of your correspondents have disagreed with the contention of my letter (Dec. 18, 1948, p. 1078) and of Dr. A. Cyril Wilson's (Feb. 12, p. 284) that there are objections to the routine use of rectal thermometers for young children.

Dr. Lise Gellner (March 26, p. 547) dismisses with "amusement" the belief that early events such as this may later cause psychiatric disorders, apparently holding as proof the fact that Continental mothers all interfere with their babies in this way.

Yet there was a time when Continental mothers as well as English ones cheerfully fed children upon rachitic diets, quite unaware of subsequent eventualities. The risk of disturbing a growing personality is no less serious than the risk of disturbing bony development.

Dr. A. A. MacDougall (March 12, p. 457) does not see that it interferes more to put a thermometer into the rectum than into the mouth or axilla. But it is natural for objects to go into the mouth, not into the rectum. I doubt he would maintain this standard had he seen children from a "modern" school playing "doctors" with imaginary rectal thermometers. Children can be consistent. Nor can I agree with him that vaginismus appears only in the psychopath. Out of 159 consecutive cases of vaginismus (most of them severe, being sent in consultation) no less than 56 actually remember that rectal interference was *de rigueur* in the nursery. Such a proportion is not likely to be chance; and I think others dealing with these cases should find a similar percentage, particularly if they remember to enquire about local treatment for threadworms or can ask the mother about soap-sticks in infancy.

Whilst no one suggests that the majority of children so treated suffer ill consequences, clearly one cannot foretell when lasting impressions may occur. During this correspondence I have had personal letters from psychiatrists and others confirming these views. I therefore still maintain that those in charge of infants' wards should not consider that rectal interference is necessarily a trivial or a harmless practice.—I am, etc.,

London, N.W.1.

JOAN MALLESON.

POINTS FROM LETTERS

Is Influenza Epidemic?

Dr. A. H. GREGSON (Cromer) writes: With reference to the annotation entitled "Is Influenza Epidemic?" (March 12, p. 448), I apologize for the dogmatism of the following, but it is a purely clinical observation. There seems little doubt that the present influenza epidemic consists of three separate types—(1) and (2) harmless, (3) potentially fatal. (1) The patient presents with aching in the limbs and nausea, with a temperature of up to 100° F. (37.8° C.) and perhaps headache and vomiting. This responds in a few hours to intestinal antiseptics such as benzyl benzoate, or iodochlorhydroxyquinoline 0.25 g. thrice daily. (2) "Classical" influenza, with aching limbs, head, and trunk, some photophobia, pyrexia to 103° F. (39.4° C.), and no chest signs. This can be treated according to taste. (3) A dangerous "bronchial" influenza, which is really a bacillary bronchopneumonia plus aching limbs, head, and trunk, temperature of 99°–103° F. (37.2°–39.4° C.), and very often a true vertigo of labyrinthine type but not often showing nystagmus. In its early stages this type may not on superficial examination show any such signs, but the following test, first described I think by Hughes in 1842 (*Guy's Hosp. Rep.*, 1842, 7, 298) settles the matter: "The patient gives a forcible cough and an immediate deep inspiration through the open mouth. At the end of inspiration there is a mixed 'whiffling' sound with momentary bronchial breathing and sometimes a few momentary rhonchi." In my own experience of this test over some years a faint "plop" at the end of the forced inspiration is an even earlier sign. Either result means the same thing—incipient broncho- or lobar pneumonia.

Psychiatric Indications for Abortion

Dr. A. HARGREAVES (Rickmansworth, Herts) writes: In the letter of Dr. Ellis Stungo (April 2, p. 591) it is stated in reference to the psychiatric indications for abortion, "Obviously they have no football pools in Switzerland." This is incorrect. There is a well-organized pool, the surplus from which is devoted to the benefit of athletic and sporting organizations. . . . Whether this detail affects the validity of his argument I am not sufficient of a psycho-gynaecologist to determine.

Diagnosis of Early Pulmonary Tuberculosis

Dr. E. A. WOOD (St. Leonards-on-Sea, Sussex) writes: I sympathize with Dr. Reginald Fisher (April 2, p. 591), and perhaps my suggestions as to which patients to examine by x rays, briefly reported in the *Journal* of Sept. 27, 1947 (p. 487), will be more helpful. He will not forget, I am sure, to have sputum examined when there is any; though a "negative" should not preclude x-ray examination indicated on other grounds.

Dr. WALTER WYNNE died at Northiam, Sussex, on March 7 at the age of 81. He was born at Ruthin, North Wales, in May, 1867, and received his medical education in Edinburgh, graduating M.B., C.M. in 1888. In the early 'nineties he started practice at Northiam, and remained there for the rest of his life, retiring in 1934. Dr. Wynne was a fine type of general practitioner and was much loved and respected over the wide area of his practice. He was fond of shooting, fishing, cricket, tennis, and all country things, and he had a great sense of humour. In 1935, following the shock of the death of their younger daughter after an operation, Mrs. Wynne and he went on the world tour arranged in connexion with the B.M.A. meeting in Melbourne. He took an active part in all the scientific and social aspects of the tour. Not long after his return he had a further blow in the death of his younger son. For many months Dr. Wynne suffered from a distressing paralytic condition, which he bore with great fortitude, only taking to his bed on the day of his death. The sympathy of his colleagues and friends will be extended to his widow and to his surviving daughter and son.—G. L. B.

Dr. ROBERT TENNANT BRUCE died on March 14 after a painful illness lasting more than a year, borne with quiet and uncomplaining fortitude. He was born in 1872 in Edinburgh, the son of the late Dr. Robert Bruce. Educated at Edinburgh Academy and Edinburgh University, he graduated M.B., C.M. in 1894, and after an assistantship in general practice he joined the late Dr. Gowans as a junior partner at Broughty Ferry, Angus. A few years later he came to London, and in 1903 he proceeded M.D. He then practised at Thame, Oxfordshire, where his skill and kindness soon became well known. In 1914 he joined the R.A.M.C. and served with a field ambulance in the 51st Division in France. Later he did a spell of duty as a regimental medical officer, and was taken prisoner. Later still, after his release, he commanded an ambulance train in France. After being demobilized he retired from practice and settled in London, where he was able to indulge in his many hobbies—climbing, travel, literature, carpentry, photography, chess, bridge, and croquet. In 1903 he married Caroline Taylor, daughter of David Wybrants, of Dundee, who survives him; to her the sympathy of Robert Bruce's innumerable friends will be extended.

Dr. PHILIP NEWMAN GRINLING died at his home in Sheffield on March 14 at the age of 41. He graduated M.B., B.S. at Armstrong College, Durham, in 1930, and was soon afterwards appointed house-surgeon and later house-physician to the Royal Victoria Infirmary at Newcastle-upon-Tyne. Following a period as an assistant he settled in general practice in the Firth Park district of Sheffield. There he rapidly built up a large practice which he conducted for the rest of his brief life. He was remarkably successful in the new sphere of industrial medicine, in which he had a niche of his own, particularly with the largest steel concern in Sheffield. He gave a great deal of time and energy to the St. John Ambulance Association. If he thought anything worth doing at all he expended all he had in him upon it, otherwise he left it alone. He was a member of all the important local B.M.A. committees in turn, and was secretary of the local public relations committee and a member of the Yorkshire Branch council. He never sought popularity, and in fact was courageous in his defence of unpopular issues and his lack of tolerance for any form of muddled thinking. Yet as a friend he was ever kindly and true as steel. It was painful for those who were his friends to see him struggling in recent years, when a never robust constitution was letting him down badly. We shall miss him greatly.—W. E. D.

The Services

Colonels (Honorary Brigadiers) F. R. Sandford, C.B.E., M.C., T.D., and G. J. V. Crosby, C.B.E., T.D., R.A.M.C., T.A., have been appointed Honorary Physicians to the King, in succession to Colonels H. F. Humphreys, O.B.E., M.C., T.D., retired, and R. Errington, C.B.E., M.C., T.D., retired.

Surgeon Commander G. A. Mason and Surgeon Lieutenant-Commander C. P. Nicholas, R.N.V.R., have been awarded the R.N.V.R. Decoration.

DANGEROUS DRUGS IN CARS

The case is reported¹ of a doctor who was fined £5 for failing to keep dangerous drugs in a locked receptacle. They were left in his locked car, which was stolen. When the case was heard on March 11 the prosecution did not dispute that the car was locked; it was stolen from the municipal car park while the doctor was at the cinema. When it was recovered the prosecution, an open leather case containing drugs was found on the rear seat. Counsel for the defence disputed the view that a locked car is not a receptacle and so that if the prosecution's contention was upheld it would put the whole medical profession in a most difficult position. The stipendiary magistrate, Lord Ilkeston, said in his judgment: "In my opinion a locked car is not a receptacle within the meaning of the word as used in paragraph 4 (2) of the Dangerous Drugs Regulations, 1948." He agreed to state a case. When the Dangerous Drugs Regulations, 1948, were published a Home Office notice accompanying them² stated that the Secretary of State is advised that a car cannot be regarded as a receptacle. The law is uncertain on how a doctor must leave dangerous drugs in an unattended car. It would seem to be necessary for him to lock both the car and the case in which the drugs are kept. Probably the locked case would be regarded as a proper receptacle and the locked car as a proper place for the receptacle to be kept, though it is uncertain what view the courts would take of this. To be on the safe side doctors would be well advised to attach the case to the car by means of a padlock and chain, and leave the car locked. It is a sufficient precaution to leave a locked case in an unlocked car.

Universities and Colleges

UNIVERSITY OF ABERDEEN

At a Graduation Ceremony on March 31 the following medical degrees were conferred:

M.D.—1 R. G. Simpson, 2 G. Sangster, P. H. Beattie.
M.B., Ch.B.—A. R. Adams, Mary P. H. Lewis, A. Nicol, N. A. Regan, Joan Smith, R. F. F. Steven, J. A. Tallack.

¹ With honours for thesis. ² With commendation for thesis.

UNIVERSITY OF EDINBURGH

Dr. Douglas Guthrie, Lecturer on the History of Medicine, will deliver a series of lectures entitled "The Historical Approach to Medicine" in the Physiology Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, on May 2, 9, 16, 27, and 30 and June 6, 13, and 20, at 5 p.m. The course is open to all matriculation students and graduates of the University, and to members of the University staff, without fee. Others may attend on payment of entrance fee of 10s. in lieu of the matriculation fee.

UNIVERSITY OF LONDON

The degree of D.Sc. has been conferred on Frederick Robert Selt, Ph.D., M.D., Reader in Bacteriology at Middlesex Hospital Medical School.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS GLASGOW

The following have been admitted Fellows of Faculty *qua* Physicians: J. F. Smith, M.D., R. A. Blair, M.B., J. Crorie, M.B., S. K. Gang, M.B., G. H. V. Keshani, M.B., Margaret M. O'Hare, M.B., C. Ross, M.B., I. A. Short, M.B., Mary D. Smith, M.B., R. A. Stewart, M.B., F. H. Stone, M.B., W. O. G. Taylor, M.B., R. Thomson, M.B., J. D. Woods, M.B.

The following have been admitted Fellows of Faculty *qua* Surgeons: A. A. Bonar, M.B., E. Cameron, M.B., R. K. Dewar, M.C.P.&S.O., J. Ferrier, M.B., J. D. Fraser, M.B., T. B. Gardiner, M.B., J. Jalundhwala, M.B., G. Johnstone, L.R.C.P.&S.Ed., M. T. Khale, M.B., D. MacLeod, M.B., D. A. Macpherson, M.B., A. L. Mort, M.B., J. F. P. Mullins, M.B., R. M. Nadkarni, M.B., T. R. Richmond, M.B., N. T. Sampanthan, M.B., M. Shaw, M.B., R. Sinha, M.B., G. Smith, M.B.E., M.B., R. A. Tennent, M.B., M.B., J. K. Watt, M.B.

VINESTHENE

ethyl divinyl ether

is an inhalation anaesthetic indicated especially for short anaesthesia.

It is particularly useful for children and is administered most economically by the closed method.

With 'Vinesthene', induction is rapid, anaesthesia is smooth and muscular relaxation is good.

The absence of excitement and struggling during the induction stage is a valuable factor when this anaesthetic is used for dental procedures and in Hospital Out-Patient Departments.

Compared with ethyl chloride, induction with 'Vinesthene' is much easier, there is not the same tendency to breath-holding or muscle spasm, and incidence of post-operative sickness would appear to be much less.

When the open method of administration is advocated

'Vinesthene' is best **VAM** trade mark
used in the form of brand

which is a mixture of 1 part of 'Vinesthene' and 3 parts of ethyl ether.

This gives a more even plane of anaesthesia than 'Vinesthene' and overcomes the disadvantages of open ether, particularly enabling a greater degree of relaxation to be obtained.

OUR MEDICAL INFORMATION DIVISION WILL
BE PLEASED TO SEND A COPY OF THE
MEDICAL BOOKLET 'VINESTHENE'
ON REQUEST.

Adequate supplies of these two products are now available.

'VINESTHENE' in containers of 25 c.c.

boxes of 6 x 3 c.c. ampoules.

boxes of 6 x 5 c.c. ampoules.

and

'VAM' in containers of 4 oz.

The proteolysed extract of liver for parenteral use

NEO-HEPATEX

PROTEOLYSIS—Original research in the Evans laboratories has shown that a better liberation of active principles from protein complexes, and an enhanced therapeutic potency can be obtained by the application of controlled proteolytic enzyme digestion to liver in the manufacture of anti-anæmia preparations.

POTENCY—Each batch is clinically tested before issue to ensure that a dose of 2.0 c.c. every fourteen days will restore the blood picture to normal in the average uncomplicated case of pernicious anæmia. A maintenance dose of 2.0 c.c. per month is usually adequate.

GREEN CORN AT HARVEST TIME

EVERY practising physician has
observed the increase in what may
be termed "the cult of sub-normal
health."—particularly among young
girls.

Usually the positive signs are few.
They may well be psychogenic.

If the presenting symptoms are
debility, with lethargy, constipation,
lustreless hair, adenoids and catarrhal
disorders an iodine-deficient thyroid should come high on the
list of differential diagnoses.

Adequate iodine intake even in known goitre areas would
be assured by the addition of iodine to table salt, as recom-
mended by a subcommittee of the Medical Research Council.
Medical men are invited to write for **WORLD GOITRE
SURVEY**, which presents a summary of world knowledge
on the use of iodine in the treatment of goitre and its allied
conditions. **WORLD GOITRE SURVEY** will be sent free
of charge to any interested medical practitioner.

CALGITEX

SODIUM ALGINATE SOLUTION
AND
CALCIUM CHLORIDE SOLUTION
IN
THORACIC SURGERY

EXTRAPLEURAL PNEUMOTHORAX would probably have a
larger place in collapse therapy were it not for the complica-
tion of haemorrhage into the space.¹ In this connection, the
technique of using Sodium Alginate Solution in conjunction
with Calcium Chloride Solution has proved very successful in
arresting haemorrhage. Its application is easy and no un-
favourable reactions or toxic effects have been noted. The
solutions are compatible with penicillin and other antibiotics.

FOR EXTERNAL USES the Solutions are invaluable for
arresting haemorrhage in minor cuts or wounds—when
applied they form a firm transparent film which is absorbed
during healing.

ROYAL COLLEGE OF SURGEONS IN IRELAND

The following candidates received the Fellowship of the College on April 1, having passed the examination on March 10: J. S. Martin, M. S. Strong, J. C. de R. Sugars.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council, held in the College House on March 26, with the President, Sir William Gilliat, in the chair, Miss Josephine Barnes was appointed to serve on the Population Investigation Committee of the Eugenics Society. Mr. R. C. Thomas was appointed to represent the College on the Council of the Queen's Institute of District Nursing.

Harold Renton (South Africa) was elected to the Membership.

The following were elected to the Fellowship: Doris C. Bates, R. B. Charlton, K. M. K. Duff, M. D. A. Evans, J. D. S. Flew, B. Gilbert, J. W. Johnstone, W. I. C. Morris, Margaret M. Nolan, H. L. Sheehan, D. F. Standing, C. K. Vartan, W. Waddell, W. W. Wilson, R. G. Worcester.

A prize for an essay on the "Physiology or Management of the Third Stage of Labour" was divided between Dr. Jean R. C. Burton-Brown (Oxford) and Dr. David A. Fletcher Shaw (Manchester).

Medical Notes in Parliament

Analgesia in Childbirth

Lady TWEEDSMUIR asked Mr. Bevan on March 31 at what date he asked the Medical Research Council to solve, as quickly as possible, the problem of finding a safe and effective analgesic agent for midwifery.

Mr. BEVAN replied that there was no need to make that request, because the Medical Research Council, as he was aware, took into consideration the recommendation made in this matter by the Working Party on Midwives and had decided to set up a committee in accordance with that recommendation. He hoped that before long a much cheaper and more easily transportable apparatus would be produced. That would not be allowed to interfere with provision of transport for midwives, which was proceeding at an accelerated rate. He had impressed on local authorities that they should not delay provision of apparatus in the hope that a lighter apparatus would become available.

Dr. SEGAL asked what was the lowest cost of apparatus for the administration of trilene analgesia in obstetrics.

Mr. BEVAN answered that there were several types of apparatus, all of which were portable. The lowest price of the types on the market was, he understood, about £7. The suitability of existing apparatus for use by midwives in domiciliary cases would be among the matters investigated by the expert committee appointed by the Medical Research Council. It was not yet certain that it was safe for midwives to use the trilene apparatus without assistance.

Replying to Mr. PETER THORNEYCROFT, Mr. BEVAN said there were eight county or county borough councils in whose areas no analgesia was being used in the domiciliary midwifery service. They were: Merioneth County and the county boroughs of Bath, Burnley, Chester, Dudley, Merthyr Tydfil, Nottingham, and St. Helens.

Mr. WOODBURN said on April 5 that expert medical opinion was not yet agreed on the unsupervised use by midwives of any existing trilene apparatus. The Medical Research Council had decided to set up a committee to investigate the problem.

Mr. BEVAN on April 7 told Lady TWEEDSMUIR that he could not yet say when he would receive the final recommendations of the Medical Research Council on the latest types of analgesic drugs and apparatus suitable for use by midwives alone. Although existing methods would no doubt be reviewed by the committee which had been set up, the question remitted to the Medical Research Council by the Working Party on Midwives was on the possibility of devising improved methods. This was a relatively long-term project involving the initiation and conduct of actual research work. Quick results were not to be expected.

Number of Patients

Mr. BOSSOM asked on March 31 what estimate Mr. Bevan had made for the purposes of the National Health Service of the number of patients which a doctor could reasonably be expected to see in a day or an hour.

Mr. BEVAN said the number of patients a doctor could attend varied according to the circumstances of his practice. No

precise estimate was possible. The figure of 4,000 was the maximum which the British Medical Association agreed that any doctor should have upon his list, but there were doctors with lists of 4,000 who had fewer patients to attend than had some doctors with a list of only 3,000. In parts of the country where the average age of the population was high, a higher percentage of people would need to see the doctor.

Beds for Emergency Cases

Dr. SEGAL on March 31 asked Mr. Bevan to arrange for at least one bed for the admission of emergency cases to be reserved nightly in all hospitals of over 200 beds.

Mr. BEVAN would not do this. He said hospitals normally reserved the number of beds shown by experience to be needed, and in emergency put up extra beds. There was more demand for beds to-day and many more beds to meet the demand.

Sir HENRY MORRIS JONES said that before the Health Service Act came into force no hospital in London or elsewhere refused emergency sick cases. Was Mr. Bevan aware that, in London particularly, medical men had to be on the telephone for over an hour every day trying to get sick people into hospital?

Mr. BEVAN said Sir Henry was inaccurate. Before the passage of the Act it was often difficult to get emergency cases into hospital. There was now fixed responsibility. Formerly responsibility was diffused and no one knew about the complaints. All vacant beds in London were filled up nowadays by the end of the day. Where there were emergency cases, emergency beds were established in order to deal with them. There would inevitably be instances of delay, but the Ministry would try to cut the delay down.

N.H.S. Locums

Mr. BEVAN on April 7 told Sir WALDRON SMITHERS that he would not take steps to pay for a locum tenens when a doctor in the National Health Service was ill or incapacitated. He added that in fixing the remuneration of general medical practitioners full account was taken of practice expenses. The cost of employing a locum tenens where necessary formed part of these expenses.

Hospital Staff and Beds

Asked by Dr. BROUGHTON on April 7 what increase there had been in the number of staffed beds for the acute sick in general hospitals in England and Wales since the date of the coming into operation of the National Health Service Act, Mr. BEVAN replied that figures for beds for the acute sick as such were not readily available. Between June 30 and Dec. 31, 1948, the increase in the number of staffed beds in general hospitals in England and Wales was 15,510.

Maternity Packs and Dressings

Dr. COMYNS on April 7 asked where expectant mothers attending antenatal clinics should obtain maternity packs and dressings for the lying-in period.

Mr. BEVAN said local health authorities should arrange for maternity outfits for domiciliary confinements to be supplied at clinics, through midwives, or in some other convenient way, and for other dressings required during the lying-in period to be provided by the midwife in attendance. Maternity outfits and sterilized dressings were not included in the schedule of appliances which a general practitioner could prescribe for his National Health Service patients.

Vitamins in Bread

Mr. STRACHEY, replying to Dr. BARNETT STROSS on April 4, said that there was no vitamin A in bread. The comparative figures for the vitamin B₁, B₂, and calcium of the national and pre-war white bread were (in milligrams per oz.):

	National	White
Vitamin B ₁ ..	0.063	0.015
Vitamin B ₂ ..	0.028	0.013
Calcium ..	31	3

During the past four years the rate of extraction of national flour has varied between 80% and 90%. The current rate of extraction is 85%. National flour is reinforced with calcium (creta preparata) at the rate of 14 oz. per 280 lb.

Streptomycin.—Mr. BEVAN said on March 31 that the production of streptomycin was now sufficient to cover all medical needs and to provide small but increasing quantities for export. Further expansion was planned. Since July, 1948, the number of hospitals in England and Wales where streptomycin treatment was available had increased from 30 to 220.

No. 12

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Infant Mortality, Stillbirths, and Abortions

A quarter of a million, or 1 in 8, of the children that might have resulted from two million pregnancies in the three years 1936-8 were lost as a result of spontaneous abortion, stillbirth, or death in the first twelve months of life. This estimate was made by Titmuss and quoted by the Joint Committee of the Royal College of Obstetricians and Gynaecologists and the British Paediatric Association in the report, *Neonatal Mortality and Morbidity*, discussed in a recent leading article (*Journal*, March 12, p. 444). This figure of 250,000 is so striking that it seemed of interest to examine it. During the three years there were 1,837,053 live births. The losses included 74,580 stillbirths, 103,324 deaths of infants under 1 year of age, and, according to Titmuss, 90,000 abortions, excluding criminal abortions. Titmuss did not give the details on which his estimate of abortions was based nor did he indicate whether this figure was really representative of the whole population. Consequently it is not clear whether this is a conservative estimate or not. However, the two official figures and the 90,000 estimate give a total loss of 267,904 infants or potential infants—appreciably more than the quoted quarter of a million. If to this figure is added the known total of live births (1,837,053) the total pregnancies in the three years were just over the two-million mark—2,001,633. The proportion of pregnancies which yielded children who did not survive a year, on this basis, is 267,904 : 2,001,633, which would correspond to a rate of 134 per 1,000. Large as this rate may seem, the infant mortality alone exceeded this level at the beginning of the present century. Improvements have taken place in the ten years since 1936-8, and the figure of 1 in 8 has now been reduced to something of the order of 1 in 12.

Discussion of Table

In *England and Wales* there was a rise in the notifications of scarlet fever 148 and whooping-cough 188. There was a decrease in the incidence of measles 968 and cerebrospinal fever 18.

The largest rises in the incidence of scarlet fever were those of London 42, Surrey 30, and Lancashire 26. The chief variations in the notifications of whooping-cough were increases in Lancashire 90, Kent 36, and Middlesex 31, with decreases in London 40 and Oxford 23.

The largest falls in the notifications of measles were Yorkshire West Riding 206, Middlesex 188, Lancashire 166, Staffordshire 160, Essex 158, Yorkshire North Riding 121, Southampton 110, and Surrey 101. The only outstanding exception to the declining trend was a rise of 101 in Sussex. There was no appreciable change in the notifications of diphtheria.

Of the 34 cases of dysentery 15 were notified in Lancashire (Liverpool C.B. 9; Preston R.D. 4).

Deaths from influenza in the great towns were 33 fewer than in the preceding week. A small decline occurred in every area except in the Midland and North Midland region, where an increase of 21 was recorded.

In *Scotland* there were increases in the notifications of measles 48, dysentery 13, and diphtheria 12, while a decrease was reported for whooping-cough 28. The increase in the incidence of dysentery and diphtheria occurred in the western area; in Glasgow the increases were 5 and 12 respectively.

In *Eire* there were increases in the notifications of whooping-cough 65 and diarrhoea and enteritis 18, while a fall of 38 was reported for scarlet fever. The rise in the incidence of whooping-cough and diarrhoea and enteritis was mainly due to the experience of Dublin C.B. No further cases of scarlet fever were notified from the outbreak in Donegal, Stranolar R.D., where 31 cases were notified in the preceding week.

In *Northern Ireland* the largest change in the weekly totals was an increase of 10 in the notifications of measles.

Quarterly Returns for Scotland

The births during the December quarter were equivalent to a rate of 18.5, which was 0.2 below the average of the fourth quarters of the five preceding years. The infant mortality was 44 per 1,000 registered live births, the lowest rate ever recorded for a fourth quarter, and 13 below the rate for the fourth quarter of 1947. The general death rate of 12.2 per 1,000 was 0.6 below the five-years average. The death rate for the principal epidemic diseases was 8 per 100,000, compared with an average of 25 for the corresponding quarter of the five preceding years. The chief causes of death in this group were influenza 52, whooping-cough 20, cerebrospinal fever 12, and diphtheria 9. The death rate for all forms of tuberculosis was 74 per 100,000, and for respiratory tuberculosis 67. These rates are respectively 1 and 7 above the five-years average.

Week Ending April 2

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,257, whooping-cough 2,998, diphtheria 105, measles 15,819, acute pneumonia 1,481, cerebrospinal fever 30, acute poliomyelitis 13, dysentery 62, paratyphoid 2, and typhoid 1

Medical News

Lord Boyd-Orr

Lord Boyd-Orr, formerly Director General of the United Nations Food and Agriculture Organization, was made an Honorary Fellow of the Royal College of Physicians of Ireland on April 5

Lord Addison

Viscount Addison has resigned his office as Paymaster General. He retains his post as Lord Privy Seal, and continues to be Leader of the House of Lords. He is succeeded by Sir Gordon Macdonald, retiring governor of Newfoundland

Broadmoor

Broadmoor Criminal Lunatic Asylum was transferred on April 1 to the responsibility of the Minister of Health from that of the Home Secretary, under whose charge it has been since it was opened in 1863. The asylum is now managed by a Board of Control, and its address is Broadmoor Institution, Crowthorne, Berks. The institution is part of the mental health services incorporated in the National Health Service. While the Board of Control is responsible for running the institution, decisions on the admission and discharge of patients will continue to rest with the Home Secretary. There are at present 869 patients—682 men and 187 women

Care of Cripples

The Central Council for the Care of Cripples has issued a useful pamphlet showing how, by close co-operation between the voluntary organizations and the various statutory bodies, the physically handicapped can receive full benefit from the provisions made for their well-being. In the first part detailed instructions are given on how to start and run local associations efficiently, and the second part contains excellent explanatory notes on the relevant Acts. It concludes with a list of voluntary organizations and their addresses. Copies may be obtained for 2s from the Central Council at 34, Eccleston Square, London, S W 1

David Anderson-Berry Prize

A David Anderson-Berry silver-gilt medal, together with a sum of money amounting to about £100, will be awarded in 1950 by the Royal Society of Edinburgh to the person who in the opinion of the council has recently produced the best work on the therapeutical effect of x rays on human diseases. Applications for this prize are invited. They may be based on both published and unpublished work and should be accompanied by copies of relevant papers. Applications must be in the hands of the general secretary, Royal Society of Edinburgh, 22, George Street, Edinburgh, 2, by March 31, 1950

Pollution Control in the U.S.A.

As a result of the passing of the Water Pollution Control Act in the U.S.A. last year a nation-wide scheme has been started to improve water supply and sewage disposal as well as to eliminate pollution of streams by industrial wastes. A Water Pollution Control Advisory Board is being established under the United States Public Health Service to give technical assistance and advice. Fourteen river-basin offices are being set up in different parts of the U.S.A. to carry out the scheme, and they will encourage local understanding of the need for pollution control, since it is from communities themselves that requests for aid must originate

Cooling of Ice-cream

The Ministry of Health announces that after May 1 ice-cream manufacturers will no longer be able to plead the special defence that they have ordered but been unable to obtain the necessary apparatus in any proceedings for failure to install suitable cooling apparatus. The Minister is satisfied that suitable cooling apparatus is now available in sufficient quantity to meet all the prospective demands of the trade. The special defence was introduced in the Ice Cream (Heat Treatment, etc.) Regulations, 1947, because at that time there was a serious shortage of cooling apparatus, and it was later extended to May 1, 1949, by subsequent regulations. After May 1 it will be necessary for the requisite cooling apparatus to be installed in all premises where ice-cream is manufactured other than from a complete cold mix

Award for Prevention of Blindness

Dr Lawrence T. Post, of St. Louis, U.S.A., has been awarded the Leslie Dana Gold Medal for 1948 for "outstanding achievement in the prevention of blindness and the conservation of vision." The award is given on the recommendation of the Association for Research in Ophthalmology. Dr. Post is Professor of Clinical Ophthalmology at Washington University Medical School

Medicine in Singapore

The King Edward VII College of Medicine Alumni Association, which was reconstituted in 1947, now issues its *Proceedings* as an occasional periodical. The first number includes original articles on malaria, parasitology in Malaya, and helminthic parasites, and reports of cases on a wide variety of medical disorders. It is edited by Dr B. R. Sreenivasan in conjunction with an editorial board which includes Professor G. A. Ransome

Wills

Sir Edward Stewart, formerly vice chairman of the British Red Cross Society and on the staff of St. Marylebone General Dispensary and the Royal Chest Hospital, left £55,974. Dr. Susan Sutherland Isaacs, the well-known child psychologist, left £2,849. Dr. Edmund Spencer Hemsted, of Kintbury, Berks, left £115,904

COMING EVENTS

Postgraduate Lectures

The Royal College of Obstetricians and Gynaecologists has arranged a postgraduate course of advanced lectures for those studying the special practice of obstetrics and gynaecology, to be given at the College House, 58, Queen Anne Street, London, W., from Monday, April 25, to Friday, April 29, inclusive, at 12 noon and 5 p.m. each day. The fee for the course of ten lectures is 4 guineas (10s. 6d. for a single lecture). Admission is by ticket only, obtainable from the Secretary

Port Health Authorities

The Association of Sea and Air Port Health Authorities of the British Isles will hold its 50th Annual Meeting at the Town Hall, Newport, Mon., on April 27-29. Papers to be read include: "Imported Fats," by Dr. Stuart I. A. Laird, "Water," by Major W. W. Marsden, "The Control of Water and Food Supplies on Air Routes," by Sir Harold Whittingham, "Some Experiences of an Army Hygiene Officer, 1939-45," by Dr. L. H. Murray, "Port Health and its Relation to Allied Services," by Dr. T. L. J. Coxon. Particulars may be obtained from the honorary secretary of the association, Dr. H. C. Maurice Williams, Health Department, Civic Centre, Southampton

American Congress on Obstetrics and Gynaecology

The International and 4th American Congress on Obstetrics and Gynaecology will be held on May 14-19, 1950, at the Hotel Statler, New York City. It is sponsored by the American Committee on Maternal Welfare. General sessions will be held to discuss the following topics: (1) "Physiology of Human Reproduction," (2) "Pathology of Human Reproduction," (3) "Social and Economic Problems," (4) Neoplastic Diseases of the Female Reproductive System, (5) "Obstetric and Gynaecological Procedures." Information may be obtained from Dr. Fred L. Adaire, 24, West Ohio Street, Chicago 10, Illinois, U.S.A.

Royal Sanitary Institute Congress

The council of the Royal Sanitary Institute announces that the presidents of the sections of the Health Congress to be held at Brighton on May 23-27 will be as follows: Preventive Medicine: Professor Andrew Topping, Engineering and Architecture: Sir Lancelot Keay, Maternal and Child Health: Professor W. S. M. Craig, Veterinary Hygiene: Mr. H. T. Matthews, Food and Nutrition (in conjunction with Food Group, Society of Chemical Industry): Dr. E. B. Hughes, D.Sc.; Housing and Town Planning: Mr. J. W. R. Adams, Tropical Hygiene: Professor P. A. Buxton, F.R.S., Hygiene in Industry: Professor T. Ferguson. The president of the conference of medical officers of health will be Professor R. H. Parr. A discussion on "The Hospital and Medical Services" in the Preventive Medicine section will be opened by Brigadier J. L. Glyn Hughes and Mr. Henry Lesser. At the Conference of Medical Officers of Health Dr. C. Metcalfe Brown will speak on "Public Health Research," and Dr. J. Stevenson Logan will introduce a discussion on "For and Against Institutional Midwifery." In the Tropical Hygiene section Dr. P. C. C. Garnham will speak on "Modern Concepts in Malaria Control," and Dr. W. Berry on "The West African Groundnut Scheme." There will be a symposium on "The Care and Preservation of Fish as Food."

Almroth Wright Lectures

A course of six Almroth Wright Lectures on "The Bacterial Cell" will be delivered in the Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, Paddington, London, W., on Tuesdays at 5 p.m., from May 3 to June 7. The lectures are open to all members of the medical profession and to all students in medical schools without fee. Details will be published in the Diary column of the *Journal* week by week.

Teaching Biology

"New Trends in Biology Teaching" is the theme of a two-day conference which is being held on May 6 and 7 at the Borough Polytechnic, London, S.E.1. Professor, S. Mangham will give an opening address on "Biology for To-morrow." He will be followed by Miss Hilda Franks on "Syllabuses." Dr. L. M. J. Kramer is giving a lecture-demonstration, "Preparing and Presenting Inexpensively a Year's Course Based on the Theme 'The Child's Microbial Heritage.'" At the final session Mr. Richard Palmer will talk on "Some Neglected Aspects of Human Biology in Schools." Tickets for the conference can be obtained from the British Social Hygiene Council, Tavistock House North, London, W.C.1, price 5s. (exclusive of meals).

SOCIETIES AND LECTURES**Tuesday**

SOCIETY FOR THE STUDY OF ADDICTION.—At Medical Society of London, 11, Chandos Street, W., April 19, 4 p.m., Annual general meeting; "Alcoholism as a Neurotic Symptom," by Dr. R. D. Newton.

Wednesday

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C., April 20, 5.30 p.m., "The Use of Thin Sections of Entire Organs in Morbid Anatomical Studies," by Professor J. Gough and Mr. J. E. Wentworth.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—At 28, Portland Place, London, W., April 20, 3.30 p.m., "Occupational Eye Diseases and Injuries" (I), Illustrated, by Mr. Joseph Minton.

Friday

CAMBRIDGE MEDICAL SOCIETY.—At Addenbrooke's Hospital, Cambridge, April 22, 2.30 p.m., "Some Aspects of Epidemiology," discussion by Dr. A. M. McFarlan.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At Zoological Gardens, Regent's Park, London, N.W., April 22, 7.15 p.m. for 7.30 p.m., dinner meeting.

APPOINTMENTS

BOWER, JOHN, L.R.C.P. and S.I., L.A.H., Physician, Provincial Hospital for Nervous Diseases, Farville, St. Johns, New Brunswick, Canada

DEWAR, R. DUNCAN, M.B., Ch.B., D.P.H., Medical Officer of Health, Metropolitan Borough of Deptford.

PETERS, L. B., M.B., B.S., Senior Assistant School Medical Officer and Assistant to Medical Officer of Health, Brighton Corporation.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Davies.—On April 1, 1949, to Dr. Celia Marjorie Davies (née Rapport), wife of Dr. D. L. Davies, 13, Engel Park, N.W.7, a son

Giles.—On April 4, 1949, at the City General Hospital, Stoke-on-Trent, to Ruth (née Whitley), wife of Dr. Christopher Giles, a son.

Kay.—On March 28, 1949, at Westgate, to Alexandra and Dr. David Kay, a son—Nicholas

Keat.—On April 3, 1949 to Dorothy, wife of Dr. E. C. B. Keat, a son

Lamb.—On April 3, 1949, at P.M.R.A.F. Hospital, Halton, to Joan (née Turner) S.R.N., wife of Ernest Hope Lamb, M.B., Ch.B., Squadron-Leader, R.A.F., a sister for Ernest—Susan Jane

DEATHS

Baker.—On March 19, 1949, William Thomas Baker, L.R.C.P., L.R.C.S. Ed. Duncanson.—On March 29, 1949, at Ruthin, Wales, Thomas Smith Duncan, M.B., Ch.B., of Nottingham

Hall.—On April 7, 1949, at his home, 31, The Drive, Hove, Donald George Hall M.D., F.R.C.P., J.P.

Humphreys.—On March 30, 1949, Owen Rosser Humphreys, M.R.C.S., L.R.C.P., of Cardiff

Jones.—Dunne January, 1949, Arthur Thomas Jones, M.R.C.S., L.R.C.P., J.P., of Cardiff

McKie.—On April 6, 1949, at Eastbourne, Gordon McKenzie McKie, M.R.C.S., L.R.C.P., aged 76

Wilestone.—On April 4, 1949, peacefully, at Redroof Nursing Home, Croydon, Lieut. Stone Wilestone, M.D., of Cockfield, Sussex, aged 85.

Visick.—On April 4, 1949, at the County Hospital, York, Arthur Hedley Visick, F.R.C.S., of The Old House, York

Williams.—On April 6, 1949, at Foxholes Barrs Wood Road, New Milton, Hants, Charles Rudolph Williams, M.B., Ch.B.

Wilson.—Recently, Lionel Hugh Wilson, L.R.C.P., L.R.C.S. Ed., of Sheffield

Winter.—On March 31, 1949, at Misgrove Park Hospital, Taunton, Herbert George Winter C.B.E., M.C., M.R.C.S., L.R.C.P., Broadier, late R.A.M.C.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Early Ambulation after Confinement

Q.—What are the latest views on early rising after confinements? There appears to be a volume of evidence to-day in favour of getting patients up soon after operation; how does this affect ambulation after confinement?

A.—Although letting a patient get up soon after labour is often advised and has been shown to be free from risk, it is not so popular and is not practised so widely as early ambulation after operations. The same arguments can be applied in its favour, but other considerations also arise. Very often, and especially if the patient has other young children, the pregnancy imposes a prolonged physical and mental strain, and a short period of complete rest in bed is both welcome and advantageous. Early rising, too, provides a great temptation for the woman to resume her domestic responsibilities too soon. Even in hospital practice it tends to make women clamour to return home early in the puerperium. There is also the question of the establishment of lactation, which is favoured by rest. There are, of course, counter-arguments; for instance, a woman can often breast-feed more easily sitting comfortably on a chair than propped up in bed. Indeed, it becomes almost a matter of personal opinion; yet so far many obstetricians, guided probably by general considerations such as the above, seem not to favour getting about too soon, and this is true even of those who encourage it in their gynaecological wards. Some, however, have adopted a compromise, allowing their obstetrical patients up on the fifth or sixth day. There is something to be said for selecting the treatment to suit individual patients and their circumstances rather than following a rigid routine. In the case of caesarean section, when the purely medical advantages outweigh any social disadvantages, getting the patient up on the first or second day is already widely practised—often by those who insist on the traditional stay in bed after normal labour.

Vitamin E in Heart Disease

Q.—Is there anything further to report on the claims that excellent results have been obtained in cardiac cases by the use of α -tocopherol—a vitamin-E preparation?

A.—Vitamin E is found in all body tissues, and has a variety of actions. Consequently it was tried as a therapeutic agent in many different conditions, with, as a rule, disappointing results. Vogelsang, Shute, and Shute (*Med. Rec.*, N.Y., 1948, 161, 83) reported strikingly beneficial effects in about 1,500 cases of every type of heart disease. They claimed that it was the "most effective known drug in heart disease, and certainly the safest. The percentage of cases which show improvement following its administration is high (about 80%); the degree of improvement seen in the worst cases is often marked, and allows a return to activity in many cases of great disability; the improvement continues for months, even years." Since then vitamin E has been used by a number of observers in this and other countries, but on the whole the results have been most disappointing. Makinson *et al.* (*Lancet*, 1948, 1, 102) compared results in 22 cases of angina pectoris, using vitamin E, phenobarbitone, aminophylline, and calcium lactate, and found the vitamin to be of no therapeutic value. They used a dosage of 150 mg. daily for three weeks. Ball, in a series of 10 cases of angina pectoris, using 300 mg. of "ephynal" daily for six weeks or longer, found that his results did not support the Canadian workers' claims. Levy and Boas (*Ann. intern. Med.*, 1948, 28, 1117), in 13 cases of angina pectoris and of heart failure secondary to various causes, and also Baer, Heine, and Gelford (*Amer. J. med. Sci.*, 1948, 215, 542), in 22 cases of heart disease, including patients with heart failure and angina pectoris, found the results very disappointing. Both teams of workers used adequate dosage according to the standards of Shute and his colleagues. Similar findings have been reported from Denmark (*Nord. Med.*, 1948, 37, 82). Shute (*Lancet*,

1948, 1, 301) considered that Makinson *et al.* had used insufficient dosage for too short a time, and had not given enough data about their cases. He is supported in his claims by Hickman (*ibid.*, 1948, 1, 652), who pointed out that the results may be due to a local preponderance of cases with an inadequate vitamin-E intake resulting from faulty dietary habits. Shute, however, constantly stresses that he uses the drug not as a vitamin but in relatively massive doses as a therapeutic agent. He refers to the remarkable results obtained in dogs and cattle with cardiovascular disease (Lambert, *Vet. Rec.*, 1947, 59, 355), and also to the work of Govier on the biochemical background of the clinical results. Results comparable to those of Shute have not been obtained by other workers following the administration of vitamin E to patients suffering from cardiovascular disease.

Exposure to Graphite Dust

Q.—Does graphite dust constitute a danger to health? If so, are there any precautions which can be taken to safeguard the health of those exposed to it?

A.—Mineral graphite, or plumbago, is a naturally occurring form of crystalline carbon, appearing as black soft masses or, less commonly, as crystals in igneous rocks. It is mined extensively in Ceylon, Madagascar, and West Africa, and there is also a deposit in Borrowdale, Cumberland. Graphite is used in the manufacture of electric batteries, lead pencils, grate polishes, lubricants, crucibles, and in foundries. In these manufacturing processes it is necessary for the graphite to be in the form of a fine powder, while "commercial graphite" may have added sand. The carbon content of natural graphite varies. Thus certain grades of Ceylon graphite are stated to contain between 60 and 85% carbon, while Korean graphite has a carbon content of approximately 85%. The remainder is composed of mineral ash, such as oxide of calcium, iron, or silica. Although the presence of silica in the ash has been recognized, there is little definite information about the silica content of natural graphite, but it may be as much as 5%. There is also a so-called artificial graphite with a very low silica content obtained from coal or coke by treating in electric furnaces. On the silica content will depend the risk to health of long periods of exposure to graphite dust. Precautionary measures are those for the suppression and control of the dust hazard at its source. To this end full use should be made of wet methods of working, and localized mechanical exhaust ventilation.

Pelvic Allergy

Q.—Is there such a thing as "pelvic allergy"? If so, what are its effects, how can it be identified, and how treated?

A.—Some relationship between the female genital organs and allergic states has long been suggested as a result of clinical observations. For instance, asthma may first appear at puberty or the menopause, the attacks may be associated with menstruation, and may disappear completely during pregnancy. The type of relationship is not constant, however, and may assume the opposite form. Again, symptoms referable to the pelvic organs may be manifestations of allergy—some states of pruritus vulvae and cyclical ulceration of the vagina and vulva, for example. B. Zondek and Y. M. Bromberg (*J. Obstet. Gynaec. Brit. Emp.*, 1947, 54, 1) claim to have shown that many conditions, such as menstrual tension state, migraine, angioneurotic oedema, urticaria, and cyclical keratitis, which tend to occur premenstrually are due to "endocrine allergy." They postulate that the patient is allergic to one of the hormones of her own production, and they advise desensitization by the administration of graduated amounts of the appropriate hormone, the latter having been identified by skin tests. More recently C. Macpherson (*Canad. med. Ass. J.*, 1949, 60, 54) in an article entitled "Pelvic Allergy" puts forward the view—which, as he points out, is not original—that spasmodic dysmenorrhoea in young girls can be an allergic manifestation, and he claims good results from treatment with adrenaline and antihistamine drugs. It could be argued that an endocrine antigen is unlikely in such cases because the hormone levels are at their lowest during menstruation. However, bearing in mind the fact that the basis of spasmodic dysmenorrhoea may be muscle ischaemia, it recalls the work of O. W. and G. V. Smith (*Amer. J. Obstet. Gynec.*, 1947, 54, 212) on menstrual

toxin, a euglobulin which has vasoconstrictive properties and which is liberated during menstruation. Some or all of these possibilities might well come under the unsatisfactory heading of "pelvic allergy."

There are clearly at least two problems involved: (a) general allergic reactions due to genital and endocrine functions; and (b) genital reactions as manifestations of allergic states. The whole question remains very much a matter of conjecture, and most of the suggestions mentioned above await confirmation and proof.

Contact Lenses for Myopia and Astigmatism

Q.—Can contact lenses be prescribed for a combination of myopia and astigmatism? How are they obtained, how long does it take to get them, and what is the approximate cost?

A.—Contact glasses can be prescribed for a combination of either myopia or hypermetropia with astigmatism. By presenting a spherical surface to the air the astigmatism is eliminated. To obtain the glasses a consultation should be arranged with an ophthalmic surgeon, who will determine whether the patient is suitable psychologically and the eyes are suitable physically for the lenses. On the basis of his examination of the eyes he will give directions to the technician, who will proceed with the making of the lenses. The time taken varies with the type of lenses ordered and the material of which they are made, and ranges from three weeks to three months. The cost is from 30 to 50 guineas, plus the surgeon's fees.

Essential Amino-acids

Q.—I believe that milk contains all the ten essential amino-acids. Do eggs likewise contain all ten—and are there any other non-meat products that contain them all? Can you recommend an up-to-date book on the subject?

A.—The proteins of practically all foodstuffs contain all the essential amino-acids. Gelatin is an exception. Flour contains relatively little lysine. Eggs have a high content of these amino-acids. In peas and beans the ratio of essential to non-essential amino-acids is rather lower than in meat.

Two useful books are: *Science and Nutrition*, by A. L. Bacharach (3rd ed., 1947, Watts and Co., London), and *Human Nutrition*, by V. H. Mottram (1948, Arnold, London).

Sympathectomy for Asthma

Q.—Would you please let me know what operations upon the sympathetic and parasympathetic systems have been performed for the relief of asthma, and any references in literature to the subject?

A.—The following operations have been performed upon the sympathetic and parasympathetic systems for the treatment of asthma: unilateral cervical sympathectomy (sympathetic chain and part of the stellate ganglion); stellate ganglionectomy, unilateral and bilateral; right-sided vagotomy below the recurrent laryngeal nerve; bilateral resection of the pulmonary plexus; procaine block of the stellate ganglion and upper thoracic ganglia, followed by their extirpation in cases where the asthma had responded temporarily to the block. The subject is dealt with adequately in a special chapter of 20 pages in *The Treatment of Bronchial Asthma*, by V. J. Derbes and H. T. Englehardt (Lippincott, London, 1946), which contains twenty-three references. Further references are: Gay, L. N., *Diagnosis and Treatment of Bronchial Asthma* (Baltimore, 1946); Malherbe, A., *Pr. méd.*, 1939, 47, 241; Tapella, P. A., *Prensa méd. argent.*, 1940, 27, 1553.

Sulphonamides in Pneumococcal Pneumonia and Ulcerative Colitis

Q.—(a) What is the best sulphonamide for routine use in pneumococcal pneumonia, and in what dosage? (b) What sulphonamide is advised in the treatment of ulcerative colitis? Should this be given by mouth or in the form of an enema, and what is the dosage?

A.—(a) Sulphadimethylpyrimidine (sulphamezathine), or one of the other sulphadiazine homologues, is the most suitable of the sulphonamide drugs for the treatment of pneumococcal pneumonia. In adults the oral dosage is as follows:

initially 1.5 g., followed by 1.5 g. four-hourly for two to three days; 1 g. four-hourly for the next two days; 1 g. six-hourly or a final two days.

(b) Sulphaguanidine, succinylsulphathiazole, and phthalylsulphathiazole are of value in ulcerative colitis. The third-named drug is probably the most satisfactory, and has been recommended in oral doses as large as 0.02 g. per kilo of body weight four-hourly for four weeks. Retention enemata of one of these drugs are often useful, 7 to 10 g. being dispensed in 100 ml. of water or mucilage.

Civatte's Poikiloderma

Q.—What is the aetiology of Civatte's disease, and is there any effective treatment? I have a patient who has had patches of brownish discoloration on both cheeks, with scaling and cracking of the skin of the face, for the past two years, associated with irregular menses. A dermatologist diagnosed Civatte's disease and prescribed various lotions, ointments, and later X-ray treatment combined with stilboestrol, but the skin is steadily getting worse.

A.—The aetiology of poikiloderma of Civatte is unknown. It usually affects women about the menopausal period and tends to clear spontaneously in the course of a few years. It has been thought to be dependent on some disturbance of endocrine function, adrenal or ovarian, and there does appear to be some response to oestrogen therapy in a few cases. As a rule treatment is without effect. A very similar affection, described by Riehl in 1917 and not limited to women or to this age period, is regarded as being related to the ingestion of fats or the application of creams containing tar and petroleum products.

Ganglion

Q.—I have a ganglion involving the common extensor sheath in the back of the right wrist of about six months' duration. It causes little inconvenience, but is unsightly in a doctor in practice. What is the correct treatment? Would incision, evacuation of contents, and removal of a portion of the posterior wall be likely to lead to permanent disappearance?

A.—To be strictly orthodox complete excision of the entire ganglion should be advised. But when, as in this case, it is the cause of no significant disability and little inconvenience it is tempting either to leave it alone or to attempt subcutaneous rupture of the cyst wall by very firm pressure. If operation is undertaken it should take the form of complete excision, carried out with the aid of a tourniquet under general anaesthesia. This gives the greatest prospect of permanent cure. Simple evacuation with removal of part of the cyst wall, while entailing almost as much inconvenience as complete excision, is far less likely to give permanent relief.

Stilboestrol and Seminoma Testis

Q.—A patient aged 35 was recently operated on for seminoma of the testicle. There is no evidence at present of metastases, but the possibility cannot be ruled out. Is stilboestrol, or any similar preparation, likely to be effective, as in carcinoma of the prostate? If so, what preparation and what dosage would you recommend?

A.—There is no evidence at present that stilboestrol or any other preparation is of value in cases of seminoma of the testicle. After orchidectomy for seminoma it is advisable to give a course of high-voltage x rays to the aortic lymph nodes.

Reaction to Dental Analgesia

Q.—A patient had pounding of the heart, gastric distension, and fairly severe pain in the jaw shortly after a tooth extraction. These symptoms, along with polyuria and frequency, continued until the following morning, when he obtained relief by vomiting. This appeared to be a case of acute acidosis due to the local analgesia. Is there any way of counteracting these symptoms?

A.—Reactions following injection analgesia are usually due to the adrenaline and not to the procaine or other synthetic local analgesic employed. Pounding of the heart sometimes occurs after the injection, particularly if any of the solution containing adrenaline is inadvertently injected direct into a

blood vessel. In a patient with cardiac disease the signs and symptoms may of course be more severe. Acidosis is not generally produced by local analgesia, but patients not infrequently confuse local analgesia with general anaesthesia and fast for a period beforehand. This fasting may account for acidosis. There is of course no reason why the patient should not have perfectly normal meals before any extraction involving local analgesia.

Induction of Labour

Q.—What is the best method of induction of labour for use by a general practitioner working in ordinary domiciliary practice? What is the foetal mortality, if any?

A.—It is not stated whether it is desired to induce labour at term or prematurely. In ordinary domiciliary practice the general practitioner would probably be wise to transfer to hospital patients in whom the induction of premature labour seems indicated. When pregnancy appears to be at or after term, the minimum risk to mother and foetus attaches to the induction of labour when the head is engaged, the cervix is effaced, and dilatation has begun. But when these conditions are fulfilled induction is rarely required. The safest method is a "simple induction" with castor oil, enema, and hot bath. Pituitary preparations should be used with caution and are best avoided, while quinine has fallen into disfavour because of reports of foetal death following its use. Surgical methods of induction are not generally suitable for domiciliary practice, although loosening the attachment of the membranes by a sweep of the finger inserted through the cervix is reasonably safe provided the conditions enumerated above are satisfied. The risks of induction of labour to the foetus cannot be stated in general terms; they depend to a large extent on the indication for the operation and the time at which it is done, as well as on the method employed and the state of the lower segment and cervix.

NOTES AND COMMENTS

Getting Warm in Bed.—Mr. R. D. MOTHERSOLE (Bolton) writes: It is often difficult, especially for elderly people, to get warm in bed after getting up during the night. I suppose it is a matter of common knowledge (despite the trend of modern education) that warm-blooded animals get most of the heat they need from their voluntary muscles, which act as slow-combustion stoves and immersion heaters. The fuel, I need hardly say, is glucose. But I find it is less well known, even by doctors, that by tensing one set of muscles against their opponents (e.g., flexors v. extensors) especially those of the lower limbs, but the more the better, it is possible to warm up the whole body quickly, with practically no movement of the parts concerned nor disturbance of the bedclothes.

Mind and Skin.—Dr. I. B. SNEDDON writes: My article on "The Mind and the Skin" (March 19, p. 472) was an abridged version of the paper which was given to the Sheffield Medico-Chirurgical Society on Oct. 18, 1948. I should be grateful if this correction could be made.

Ankylosing Spondylitis.—Dr. F. HERNAMAN-JOHNSON writes: I regret that the dosage of gold and sodium bismuth tartrate is not made clear in my letter in your issue of April 2 (p. 591). It is 0.001 g. of gold (as printed) and 0.5 grain (not 0.5 g.) of sodium bismuth tartrate.

Correction.—Dr. T. STEPHANIDES writes: With reference to the article "Ringworm of the Scalp: Treatment by X-ray Epilation without Subsequent Local Application" (March 26, p. 523), I would like to point out a typist's error which crept into the text. The statement "Open field 16.6 in. (42 cm.) diameter" should, of course, have read "Open field 16.6 cm. diameter." It will be noted that all the other measurements were given in the metric system only.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Allology, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the British Medical Journal alone. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 16 1949

THE SECRETARY REPORTS

N.H.S. FINANCE

How many people really know how the National Health Service is financed, what proportion of the usual employee's contribution goes to the financing of the Service, how much of the contribution goes to the family doctor? A small survey has been made for the Association by the Gallup Poll to discover the extent of the public's knowledge—or lack of knowledge—on such points. One of the most significant results of the inquiry is that only 2 out of 550

persons questioned know that the portion of the 4s. 11d. which goes to the doctor is in the region of 1d.

The facts, simply put, are that about one-eighth of the cost of the Service is met from the insurance contributions; that on average about 8½d. of the 4s. 11d. goes to the Health Service, the remainder going to unemployment benefit, sickness benefit, widow's pension, maternity benefit, retirement benefit, etc.; that the general practitioner receives about 4½d. a week (roughly 1d. from the weekly contribution and 3½d. from taxes). The full results of the inquiry are given below.

The following three questions were put to 550 men and women chosen at random in eleven districts of Central and Greater London:

1. Can you say how much you/your husband pays each week in contribution to the National Health Service?
2. Can you say what benefits this contribution covers?
3. (a) How much of your weekly contribution goes directly to the doctor?
(b) If "Don't know": is it 1d., 3d., 1s., 1s. 6d., or more than 1s. 6d.?

National Health Service

MINISTRY INQUIRY INTO G.P. REMUNERATION

The Ministry of Health has started an inquiry into the remuneration of general practitioners working in the National Health Service in England and Wales. It has circulated a questionnaire to all executive councils requiring information about payments made to all practitioners on their lists. The information is to reach the Ministry by April 23. Information about all payments made to doctors from July 5, 1948, to March 31, 1949, is to be returned. Sums which the councils should have paid, but failed to do, by March 31 are stated separately, but sums which, although earned during the period, would not normally be paid until after the close of the period will not be included.

BONDS WITH ASSISTANTS

There may be an impression that an assistant who is a trainee under the Ministry of Health scheme is in a category somewhat different from other assistants, and that the principal is protected from encroachment on the termination of the period of training. This is not so, and principals are therefore advised to enter into the usual assistantship bond with the trainee.

TEMPORARY RESIDENTS

Doctors have at last received payments for the treatment of temporary residents, but some of them may not fully understand the basis and method of payment adopted. The sum of 8s. has been paid to executive councils out of the central pool for each temporary resident attended during the two quarters ending Dec. 31, 1948. Executive councils, in making payments, were instructed to take one-third of the number of claims made by a doctor for temporary residents and credit the doctor with that number of units (a unit being equivalent to payment for an ordinary patient for three quarters) multiplied by whatever ratio of credits was in operation in the area under the old N.H.I. Act. This method of payment, as well as the amount allocated from the central pool, is provisional, and it will be reviewed by the General Medical Services Committee so that it may recommend to the Ministry the most suitable and equitable method of payment for future quarters.

EMERGENCY DENTAL TREATMENT

The Ministry of Health has devised a new procedure to facilitate the speedy dental treatment of patients who require treatment urgently. The arrangements include a new form (EC.17A), the use of which will be confined to the following items of emergency treatment: (a) not more than two extractions, (b) general anaesthetic, and (c) dressings. The fee for each procedure is 10s.

CLAIMS FOR UNEMPLOYMENT BENEFIT

Revised arrangements have been made in the procedure for claims for unemployment benefit where doubt arises whether a claimant is capable of work, or where a claimant contends that he is unfit for certain kinds of work but fit for others. Such a contention might be made in relation to the statutory dis-qualifications for refusing suitable employment or leaving employment voluntarily without just cause.

With certain exceptions such claimants will be examined by an appointed Examining Medical Officer. These officers will normally be the same as the independent Medical Referees under the control of Engagement Orders, all of whom have been invited to undertake this work, which is from the medical standpoint virtually identical.

The number of cases to be examined will probably be comparatively few.

PAYMENT OF PART-TIME SPECIALISTS

In accordance with the Spens Report on the Remuneration of Consultants and Specialists the proposed terms and conditions of service of hospital medical and dental staff (*Supplement*, March 19, p. 149) include two formulae for relating payment of part-time specialists to that of whole-time specialists. If x is the number of notional half-days worked by a part-time specialist, the part-time salary is in proportion to the whole-time salary in accordance with one or other of the following formulae, whichever gives the less result:

$$\frac{x}{11} + \frac{x}{44} \quad \text{or} \quad \frac{x}{11} + \frac{(11-x)}{44}$$

The maximum remuneration for part-time appointments is $9\frac{1}{2}$ elevenths of the whole-time salary appropriate to the grade.

The effect of this proposal is illustrated in the accompanying graph. The vertical ordinate shows the number of 44ths of the whole-time salary that the part-time specialist may earn, and the horizontal ordinate the notional half-days that he may work. Up to $5\frac{1}{2}$ notional half-days the first formula applies, and after that point the second. The maximum remuneration for part-time appointments ($38/44$ of the whole-time salary) corresponds to a working time of 9 notional half-days, and is shown by the fine-dotted line.

HEARD AT HEADQUARTERS

How They See It

The United States is taking an extraordinary interest in our National Health Service. One American medical journal, *Medical Economics*, has sent its editor, Mr. W. Alan Richardson, to make a survey of how the Service is operating, in view of the fact, as he says, that the prospect of some sort of Federal sickness insurance programme grows stronger daily in the States. Mr. Richardson, who attended the Special Representative Meetings as a visitor, is spending a month in this country. Before coming he picked out at random from the *Medical Directory* about 200 names representing a cross-section of the medical community, all the way from London to Aberdeen, and in Wales and Northern Ireland, and is endeavouring to interview as many of these doctors as he can. His schedule of questions is comprehensive and penetrating. He is here to make a balanced study uncoloured by party bias or predilection. It is gratifying to learn that he has met with the greatest courtesy and co-operation from all whom he has interviewed so far.

A Rosy Picture

Talking of the States, the *Brooklyn Eagle*, which might be compared to our *Manchester Guardian*, has column after column on the subject of our Health Service. It paints a rosy picture of its blessings. "Eyeglasses, hearing-aids, and wigs, and every possible device . . . are to be had for the asking." We are told that tens of thousands of bald men have been provided with two free wigs. Why two? That is because a man will have one to wear while the other is being cleaned and kept in good condition at a shop which gives such service at Government expense. The most enthusiastic sponsors of the Service announce, without the trace of a smile, says the *Eagle* correspondent, that untold millions now alive will live to such great ages that the nation will have to build special homes for them all over the island. Another dispatch declares that England's free National Health Service is providing everybody, even casual visitors, with anything and everything they may need for their physical and mental welfare. The general popularity of the Service, it is said, is measured by the high praise the political parties pour upon it. They are all for it, and claim it as their child. Even guarded criticism brings retribution, as it did in South Hammersmith, where the by-election was lost to the Conservatives, so says this American observer, because some of them had ventured to suggest that it was fiscally mismanaged. The average workman and his wife are delighted. In the professions and many of the "white collar" groups there is misgiving, but in the medical and dental professions themselves the chief amazement is at the absence thus far of the domination of bureaucrats.

The Milk Problem

A Joint Committee of the B.M.A. and the National Veterinary Medical Association, with equal numbers on each side, is starting some useful work. It has decided to tackle first of all the subject of milk and milk products, including the health of the cow. When that job is done it will turn to meat and meat products (presumably if by that time meat has not vanished from the British table). The committee has already had some long discussion on milk in relation to child and family health, and at its second meeting the other day it considered a long memorandum on milk distribution in which the present marketing and retailing methods were reviewed, and the question of the cleanliness of milk and the prevention of contamination at the various stages of production and delivery was gone into very thoroughly. The committee is addressing itself to the question of ensuring efficient and cheap deliveries—by efficient delivery being meant a system whereby every domestic consumer will be able to obtain, within reasonable limits, the type of milk he desires, free from any risk of disease and capable of keeping for at least twenty-four hours after delivery to his home.

Definition of Terms

When Dr. Grant, European director of the International Health Division of the Rockefeller Foundation, addressed the Institute of Almoners the other day he began by defining his terms. He said that, as he was travelling about in various countries, when people talked to him about social medicine and used similar phrases he was accustomed to ask them whether they understood semantics. "Are we speaking the same language?"—a very necessary question, especially with the new terms and phrases which are now becoming current in social and State medicine. The same difficulty of precise definition was referred to in the recent debate in the Royal Society of Medicine on specialization. The opener, Sir Robert Young, said that he consulted Dr. Johnson about the meaning of the word, but the great lexicographer had let him down. He had no definition of "specialization" to give, and of "specialty" or "speciality" he would only say that it meant "particularity." The *Century Dictionary* was not much more helpful, defining "specialization" as "the state of being or becoming a specialist." It is interesting to find Murray's first definition of "specialist" as "a medical practitioner who specially devotes his attention to the treatment of a particular disease or class of diseases," and the first reference quoted from literature to the use of the word "specialist" in that connexion is dated 1856.

The Next London Health Centre

After Woodberry Down the next health centre to be established by the L.C.C. will be at Poplar. It will be erected in the East India Dock Road, and will serve an area bounded on the north by Limehouse Cut, on the east by the railway, and on the south by the northern boundary to the West India Docks. The population which it will ultimately serve will be something like 18,000, but for the time being, until other health centres in adjoining areas are available, it will serve a population of 30,000. It will have doctors' and dentists' suites, ante-natal, post-natal, and child welfare clinics, a school treatment centre, and accommodation for ancillary services and health education. The cost is estimated at £150,000, as compared with £162,000 at Woodberry Down. The third health centre, to be included in the scheme of priorities for the year ending March, 1951, will be in Kingsland Road, Shoreditch. This will be in a converted building, and will cost only £60,000. The architect is already at work on the scheme. For the year ending March, 1952, three more health centres are on the list of priorities.

Questions Answered

Maternity Service Payments

Q.—According to the rules on Form E.C.24 the payment promised is 7 guineas and the minimal antenatal care required is the initial examination plus an examination at the 36th week. My executive council has allowed only 10s. 6d. for the antenatal visit and 4½ guineas for the confinement. The amount therefore is usually less than 7 guineas. I should be glad of your views.

A.—A fee of 7 guineas is admissible where the initial examination took place after the appointed day, a further examination was conducted at the 36th week, and where the statutory post-natal examinations are carried out (attendance at the confinement is left to the discretion of the practitioner). However, where the initial examination took place before July 5, 1948, it has been agreed that a fee of 10s. 6d. will be paid for each antenatal examination carried out after the appointed day, the practitioner looking to the patient for reimbursement for any services carried out before the appointed day.

Fitness for Work

Q.—The first sentence of a printed letter (Form R.M.2) which I have received from the divisional medical officer of the Ministry of Health reads as follows: "The above-named insured person, who is stated to be certified by you as incapable of work, has been referred by the Ministry of National Insurance for advice as to capacity for work." Unless I am guilty of deliberate wrongful certification, or my judgment is at fault, the person concerned is still unfit for work. Am I obliged to supply the particulars asked for of the case, with or without the patient's approval? Is the patient obliged to attend for examination if requested? If the regional medical officer comes to the conclusion after examining the patient that she is fit for work, and the patient and I maintain that she is not, what is then the position? Will insurance benefit be withheld, and has the patient any redress?

A.—A general practitioner is required (clause 7 (13) of Part I of the First Schedule to G.M.S. Regulations) "to furnish in writing to the medical officer within such reasonable period as the latter may specify any clinical information which he may require with regard to the case of any patient to whom the practitioner has issued or declined to issue a medical certificate." The patient is not compelled to attend for examination, but failure to attend, if requested, may result in suspension of sickness benefit.

If the R.M.O. declares the patient fit for work, suspension of sickness benefit will follow normally, but the patient has a right of appeal to a local appeals tribunal against suspension. If the patient's doctor is still of opinion that the patient is incapable of work he should continue to issue certificates of incapacity.

A CENTRAL HOSPITAL BED BUREAU

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNALORGANIZATION OF A CENTRAL HOSPITAL
BED BUREAU

BY

R. G. COOKE, M.D.

Medical Superintendent, City Hospital, Derby; Supervisor, Derby
Hospitals Central Bed Bureau

The Derbyshire Royal Infirmary and Derby City Hospitals are grouped together because for some time there has been a common waiting-list. The distribution of admissions for the first month (January) was as follows:

	From Waiting-lists	Emergencies	Others*	Total
D.R.I.	150	123	316	589
City Hospital ..	153	178	184	515
Women's Hospital ..	38	43	58	139
Children's Hospital ..	55	33	91	179
Total	396	377	649	1,422

* "Others" consist of accidents, direct admissions from out-patients, maternity cases, etc.

The proportions in the various groups differ for the various hospitals month by month according to the number of accidents and immediate admissions. At the end of the first month the state of the waiting-lists was as follows:

	On List 1/1/48	Added during January	Adm. during January	No Longer Requiring Treatment	On List 1/2/48
D.R.I.	3,590	624	303	37	3,874
City Hospital ..	266	58	38	—	286
Women's Hospital ..	210	137	55	16	276
Children's Hospital ..	4,066	819	396	53	4,436
Total					

Measures to Reduce Lists

Although all the hospitals had been working at full pressure for some time with a low average stay (varying from 12 to 15 days), the total numbers had been rising month by month for a considerable time. This was continued in the first two months of operation of the Bed Bureau, the adverse balance during this period being 589. Of the admissions 72% were immediate ones, leaving only 28% of the beds available for waiting-lists—a number quite insufficient to cope with the large number of additions to the waiting-lists. It was evident that further measures would be required, and recognized procedures were therefore dealt with more intensively.

Review of Waiting-lists.—The cases had been reviewed during the previous year and a considerable number removed, but a further review has taken place of all patients on waiting-lists

for 12 months to ascertain those who no longer require treatment for one cause or another. This has resulted in 1,164 cases being removed from the lists during the first 11 months—approximately 25% of the original number. The percentage of E.N.T. cases removed from the list on review has been lower than that of the general lists—353 E.N.T. cases were removed—but the review of these cases is not yet completed. Another factor in the difficulty of coping with the numbers of E.N.T. cases has been the fact that some of the beds of this department occasionally have to be borrowed for general emergency cases.

Towards the end of 1947 a Hospitals Co-ordinating Committee was formed in Derby. It consisted of representatives from three voluntary hospitals, a municipal general hospital, and a maternity home. The hospitals represented were: Derbyshire Royal Infirmary (339 beds), Derby City Hospital (300 beds), Derbyshire Hospital for Sick Children (84 beds), and Derbyshire Hospital for Women (60 beds).

One of the first tasks was to deal with the problem of the long waiting-lists of the hospitals. Owing to the shortage in the area of hospital beds for acute cases the combined waiting-lists of all the hospitals amounted to just over 4,000. Because of the large percentage of emergency admissions several non-urgent cases had been waiting for some years.

It was decided to set up a Central Bed Bureau, and an office was allotted in the Derbyshire Royal Infirmary. Inquiry was made in other areas. Organizations dealing with emergency admissions only were found to be in existence in London, Birmingham, and Dublin, and thanks are due for the helpful advice that they readily gave.

To try to find a comprehensive solution to the problem it was decided to deal with all cases (except booked maternity cases)—emergencies, those on waiting-lists, and private patients—through the Bureau. At a later date cases for the Isolation Hospital were also included. A separate telephone exchange is installed in the Bed Bureau Office with a number unrelated to hospital numbers, and from this exchange there is a private switch extension to the City Hospital, so that consultation is available at any time of the day or night at times when medical advice is not available in the office. The Bed Bureau telephone exchange is staffed day and night throughout the week. There are four clerks for work through the day (who also deal with all the waiting-list routine) and a rota of night telephonists. The problem is simplified considerably by the fact that the two larger hospitals have practically a common medical staff, to some extent on the unit system.

The service started on Jan. 1, 1948, and before this date the 350 general practitioners in the area were asked by circular that all applications for admission to hospital (except those for mental hospitals) should be sent to the Bureau. It was pointed out that it was the intention to facilitate admission to hospital, and that if a case required immediate admission the Bureau would undertake to provide a bed. It was also stressed that if the Bureau was to be effective it would require the co-operation and confidence of the general practitioners, and that these would not be obtained unless the service was efficient. Criticisms and suggestions were welcomed.

Size of Waiting-lists

There is a large board in the Bed Bureau office showing the bed state at all the hospitals. Hooks for each section show beds available by means of hang-on tags. As a bed is filled or becomes available a tag is removed or added as required. Direct admissions, accidents, etc., are notified by the various hospitals as they occur. The bed state is checked twice daily by telephoning the various hospitals at 9.15 a.m. and 5 p.m.

On Jan. 1, 1948, the waiting-lists were as follows:

Derbyshire Royal Infirmary	3,590
Derby City Hospital	266
Children's Hospital	210
Women's Hospital	4,066
Total	

By far the largest factor in the size of the waiting-list was provided by the ear, nose, and throat department, whose waiting cases on Feb. 1 numbered 2,260 out of 4,436—about 50%.

Use of Accessory Accommodation—Beds are used in out lying cottage hospitals, to which some patients from these areas are transferred in a pre convalescent stage. The largest measure of co operation has been received from the various cottage hospitals. During the 11 months 439 cases have been so dealt with. The local Isolation Hospital has also recently provided a small block of eight beds for convalescent cases, which is proving a great help.

More minor cases are dealt with by being admitted for one day—e.g., cases of varicose veins, certain cases of D and C etc. Certain cases doubtfully suitable for admission are brought to the out-patient departments, seen by the appropriate consultant and returned home if considered suitable. Admission of certain cases is deferred for a few days after consultation and agreement with the outside practitioner. This has resulted in some cases not requiring admission. Some institutional cases have not been admitted to hospital after consultation with the outside practitioner. The Graph illustrates the size of the lists each month.

A comparison of the numbers put on waiting-lists during the month and the numbers admitted and taken off the lists during the same month shows the following figures:

January	Debit balance	370	August	Credit balance	262
February	Debit balance	219	September	Credit	
March	Debit balance	17	balance		85
April	Credit balance	72	October	Debit balance	60
May	Credit balance	84	November	Debit	
June	Debit balance	193	balance		68
July	Credit balance	32			

The advent of the National Health Service has seen a great increase in attendance at out patient departments with consequent swelling of waiting lists. Comparative total out-patient attendances at the various hospitals for the year ending Nov 30 are as follows: 1946-7, 103,695; 1947-8 132,616.

This great increase has of course affected adversely the reduction of the lists. During the period Jan 1 to Nov 30 1948 7,260 cases were added to waiting-lists and if some scheme had not been put into operation the lists would have tended to become unmanageable. Much of this increase should not recur, and the general state is more satisfactory than it was twelve months ago. The present position is that for the medical and general surgical lists all non-urgent cases entered prior to Jan 1 1948, have now been admitted; some of these had been waiting for long periods. All cases are reviewed weekly, and all urgent cases are admitted early. Consultants visit the office regularly with advice on their cases. A comprehensive view of the problem is facilitated by the fact that all the hospitals have the same management committee. The organization has received the greatest help and co operation from hospital staffs and practitioners, and this has made the scheme workable.

When all hospitals are full and an urgent case has to be admitted (which cannot go to another hospital if in a fringe area) there is an inter-hospital arrangement whereby the local hospitals dealing with the type of case in question take it in turn to accommodate the patient. Free choice of hospital by practitioner and patient is preserved so far as practicable, but it has been found that special request for a named hospital does not arise frequently. The organization of such a service depends on a skeleton scheme as a basis and the local working out of details which will differ in different areas.

Summary

A Central Bed Bureau has been instituted for an area where there is a shortage of hospital beds for acute cases and a sharply rising waiting list. All cases, emergency and waiting list, are included. This gives a comprehensive view of the problem as a whole. The fullest co-operation of all hospital staffs and practitioners is evident. The hospitals have tended to become regarded as a single unit, and requests for a particular hospital have not been encountered often.

With the assistance of ancillary measures to save beds the waiting lists requiring admission are on a more satisfactory basis in spite of the great increase in demand consequent on the introduction of the National Health Service.

In areas where there is a shortage of hospital beds for acute cases it would seem to be desirable to institute a comprehensive scheme for admissions suiting local needs, especially in view of the greatly increased numbers of persons attending hospitals.

Correspondence

Absurdities in Pav-bed Regulations

SIR—I have been perusing the regulations for pav-bed accommodation issued by the Ministry of Health 1948 No 1490 (*Supplement* July 31 1948, p 61) and note that the fee to be paid a surgeon depends on whether the operation he performs is classified as major* (fee 50 guineas) intermediate (fee 25 guineas), or minor (fee 10 guineas).

Turning to the schedule of gynaecological operations I find that whereas hysterectomy is classified as a major operation, simple myomectomy is classified as an intermediate operation. But what is a simple myomectomy? Does it refer to the position, or the number or the size, or sizes of the fibroids in the uterus? Anyone having expert knowledge of gynaecological operations knows that the average risks of myomectomy are about the same as those of hysterectomy (Wertheim's operation excluded), while the skill and experience required for the former operation is considerably greater than that required for the latter. Myomectomy because it is conservative, fulfils a much higher ideal than destructive hysterectomy, and yet this precious schedule puts a premium on the latter.

Salpingectomy and salpingostomy (chronic whatever that means with regard to salpingostomy) did the author think there was an operation for acute tubal closure?) are likewise classed as intermediate though anyone with experience of tubal surgery knows that many of the operations for chronic tubal disease (especially when tuberculous) are exceedingly difficult and lengthy while salpingostomy particularly when performed to re-establish the patency of the inner ends of the tubes, is an exceedingly delicate and prolonged operation requiring special experience and skill.

There are many other absurdities in the schedule, but these I cite will suffice to show that whoever drew it up did not possess the expert knowledge it required or else was exceedingly careless and perfunctory. One would have thought that the Ministry would have had no difficulty in procuring acknowledged authorities on gynaecological surgery to draw up the schedule. Or is it that among the ranks of these there are no Socialists?—I am etc.

London W 1

VICTOR BONNEY

Remuneration of Specialists

SIR—Truly we live in an age where quantity overrules quality. The outbursts of criticism and comment on the terms and conditions of general practitioners under the Act, obviously unsatisfactory to all doctors, are in direct contrast to the lack of interest in the plight of the consultants, relatively a mere handful of individuals. *The Times* echoed by *The Lancet* in a leading article lays emphasis on the dissatisfaction of the general practitioners at being paid less than the consultants and the *British Medical Journal* generally appears to think the consultants are very fortunate.

Before commenting on the Minister's proposals it would be as well to capitate certain basic facts and events which must be taken into consideration.

(1) No consultant or specialist at present holding a senior post has benefited from the proposed salaries payable to trainee specialists. He has learnt his art under the old unpaid or underpaid system, conditions which he accepted in the hope of recouping the lost (financial) years when fully trained.

(2) Private practice is fast disappearing. The causes of this are the high rate of compulsory insurance levied on the erstwhile private patient, the high cost of nursing home beds (and their scarcity) and the fact that for private beds the hospitals have now doubled and in some cases trebled their charges.

(3) Consultants are to be paid for their hospital work which they previously performed free.

(4) The free consultation in the patient's home is replaced by the domiciliary scheme.

(5) The Consultants and Specialists Committee of the British Medical Association is alleged to represent all the consultants and specialists in the country. It is hard however, to see how the

members of this committee are to obtain the views of their constituents. It is understood that the Royal College of Physicians is calling a general meeting to discuss the proposals, but no word has been heard of the Colleges of Surgeons and Obstetricians and Gynaecologists or the Scottish Corporations doing likewise. The representatives of the regions will have received proposals from the staffs of the hospitals in the regions, but these representatives (of the great majority of consultants and specialists) are very much in the minority on the committee.

Bearing in mind the above facts, it is suggested that the proposals would be acceptable if adjusted in certain respects.

(1) The Spens Report, accepted in principle by the Minister and the profession, should be properly implemented. This means that the rates of remuneration should be raised to cover the 85% increase in cost of living.

(2) The fees for domiciliary visits should bear some relation to the time spent and knowledge required. The fee of 4 guineas is adequate for a patient within a hundred yards of the consultant's home, but there are not many of these. A reasonable fee should be paid according to the distance travelled in a scattered region, and allowance must also be made for the fact that a six-mile journey in London takes as long as a twenty-mile one in Devonshire.

(3) The special merit awards should be allotted purely on seniority. The jealousy and bad feeling likely to be engendered by any other system would be detrimental to the profession. Also, any system requiring recognition is likely to encourage massive publication of inaccurate and useless information with the idea of catching the assessor's eye. The busy and competent consultant will never be noticed.

(4) The mileage allowance bears no relation to the costs of a car under present conditions, to the county rates paid before July 5, or to the Whitley Council scales for local authorities. It has been rumoured that members of the Coal Board receive 2s. 6d. per mile, but I cannot substantiate this and would accept correction.

(5) Why should there be a limit to the number of domiciliary visits paid for? No other trade or profession is expected to work for nothing. No doubt the Minister fears dichotomy, and the mass of honest consultants must work for nothing lest a few black sheep steal an unnecessary fee or two.

No doubt there are other criticisms both constructive and destructive, but it would be better if they were voiced now and not, like the general practitioners', after the signature has been placed on the dotted line.—I am, etc.,

Exeter, Devon

DEREK JEFFERISS.

SIR,—Some comparisons may now be made between the proposed remuneration of whole-time National Health Service specialists and whole-time non-professorial medical university staff, and from the point of view of the latter they are most unsatisfactory.

The universities seem to have been influenced too much by the fear of possible reaction from their staffs of faculties other than medical, who have now in any case had their salaries raised. It should be a *sine qua non* that medical men receive the same treatment in all branches of the profession. To state, as has been done, that the amenities of university life compensate for less remuneration is hardly intelligent reasoning, because by virtue of his work and frequent emergency calls, day and night, the clinical worker cannot take the vacations and "time off for thinking" that the non-medical don can. Junior members of university staffs in many centres, although paid by the university, have little if any contact with academic university life, and are not necessarily members of any university college.

It would appear that in many cases the maximum salary for the university specialist is the minimum for his opposite number in the National Health Service, and he is to lose a considerable sum (the equivalent of nine months' extra salary) because the universities are not bound by a clause retrospective to July 5, 1948. The obvious solution of allowing the university specialist to be remunerated for clinical work which, after all, he carries out in a National Health Service hospital has not been accepted.

I trust that the British Medical Association will note these facts and come to the aid of a small but important branch of the profession. The only individual remedy would be to resign and take a National Health Service post. The universities, I predict, will not get the best if they adhere to their present decisions.—I am, etc.,

Oxford.

G. GORDON LENNON.

Democracy or Oligarchy?

SIR,—Most doctors hate committee work and politics—this is an axiom. The minority who take up this sort of work, whether the motive be a subconscious wish for power or a strict sense of obligation, tend to become separated from their colleagues. Usually they are beset by two dangers again: which they must be constantly on guard if they are to remain faithful to the cause they set out to serve.

In recent years the work of the medical politicians has become rapidly more and more exacting. It demands a immense amount of work, for instance, to be a useful member of the B.M.A. Council or to keep sufficiently informed of day-to-day developments to stand up effectively for medical interests on a local executive council.

As his grasp of the complex issues develops, the medical politician finds it increasingly difficult to bridge the gulch between himself and the bulk of his professional colleague who stand aloof. He begins to lose the common touch in matters political, and to bother less and less to explain his actions and consult the wishes of those whom he represents. He tends to feel, with some justification, "I'm doing this work for them. Why should I run after them? The least they can do is to keep in touch with me if they want a voice in things. And so, little by little, he may lose his basic ideal of democracy and contribute to the growth of its most dangerous weed—oligarchy.

When one finds that recommendations of the B.M.A. Council to the Representative Body, or of the General Medical Service Committee to its parent, the Conference of Local Medical Committees, are published in the national Press as if they were established policy before the profession's representatives have even met to consider them, one is moved to ponder these things.—I am, etc.,

Orpington, Kent.

A. C. E. BREACH.

Statistics of Extra Work

SIR,—It is the general opinion of the vast majority of general practitioners that the amount of work demanded by patients has greatly increased since the inception of the National Health Service Act. If this is the case, and I believe that it is, it will be necessary to prove this to the Ministry of Health beyond any shadow of doubt.

In my opinion it can be done if doctors will punctiliously enter on the back of the Medical Record Cards (Forms E.C.1 and E.C.6) every item of service rendered to a patient, no matter how trivial. The Ministry of Health's instruction "This column is provided for doctors to enter A, V, or C at their discretion" should be disregarded altogether. It should be a simple matter to compare figures obtained in this way with similar statistics which were obtained in N.H.I. days and which are already in the hands both of the B.M.A. and the Ministry of Health.

I am well aware that at the end of a busy day it is very laborious to enter up items of service in this way, but if we are to be in a position to prove our statements with regard to added burden of work in the new Service we must be prepared to make the necessary extra effort.—I am, etc.,

Belford, Northumberland.

D. T. McDONALD.

Refresher Courses

SIR,—I intended to enrol for a G.P. refresher course to be held at the University of Edinburgh, for which Government grants are available. The University confirmed that a place would be reserved for me and I applied for the grant through the usual channels.

The Department of Health for Scotland, which is responsible for financial arrangements, has now informed me that my application for a grant has been refused. The reason given is that payment of fee and expenses can be made "only for doctors who either are ex-Service medical officers or are in general practice as principals under the National Health Service arrangements." Since I am an assistant and not a principal no grant can be made to me.

It would be interesting to find out why this discrimination between principals and assistants is being made. Should not the medical standard of an assistant be just as high as that

of a principal? Surely every doctor in general practice, whether he works as a principal or as an assistant, carries an equally great responsibility towards the patient. At any rate, if the Ministry intends to exclude assistants from grants towards courses, such a decision should be made perfectly clear in advance. Although there exists a memorandum setting out the conditions (G.P.R.C.), nothing is said about the exclusion of assistants, and disappointments which could be avoided are thus bound to follow.—I am, etc.,

ASSISTANT.

Trade Unionism

SIR.—What I have to say in this letter will be acceptable to the advocates of trade unionism, but I hope to address myself with sufficient objectivity to interest at least those who are either indifferent to or antagonistic to any organization with a trade union structure.

The medical profession as a whole is realistic. It cannot change the framework of the new social order, whether we like it or not. There is no looking back, but on the contrary we must adapt ourselves with some intelligent anticipation to the future. The liberty of the profession can be enjoyed only in obedience to laws which are not irksome or oppressive yet involve control and restraint for the benefit of the whole medical community. We require, as Professor Whitehead puts it, "a doctrine as to the social mingling of liberty and compulsion."

The growth of group action in the pursuit of economic interests can be effective only if the group organization concerned can exercise adequate control over its members and those within its sphere of action. To do so we must survey the internal legal structure of the group entities which have so largely replaced the individual in the economic struggle.

The growth of trade unions and business associations leads to the replacement of individual bargaining by collective group agreements which more and more curtail the freedom of the individual by penalizing the outsider and compelling the member to submit to collective terms. It means a sacrifice of freedom in substance. This point most doctors, who think clearly and freely, have recognized, but it means an enormous change of attitude and outlook.

What are the aims of trade unionism? Perhaps the best definition is that of the Webbs: "A trade union as we understand the term is a continuous association of wage-earners for the purpose of maintaining or improving the conditions of their employment. The purpose of the trade union is the protection of the standard of life—that is to say, the organized resistance to any innovation likely to tend to the degradation of the wage-earners." These definitions are true in 1949 as in 1902, when the Webbs wrote the *History of Trade Unionism*. The purpose of trade unionism has not changed, but its methods.

Such is the influence of the movement that its co-operation is now recognized as vital in the execution of the plans of the Government. The Government is at every stage bound to consult, as other Governments did in two wars, the unions on matters of industrial and social policy. The old methods of strike, agitation, and political opposition are in the process of being replaced by negotiation and consultation on terms of equality with the employers. Trade unionism should encourage a community of interest between employer and employee, even if the employer is the State and the employee the doctor.

Unless we possess legal powers analogous to those of a trade union, both as regards withdrawal of service and the economic support which would be essential if that service is withdrawn, and we are afforded the full protection of the Trade Disputes Act, 1906, we are rendered materially impotent in our negotiations with the Government. In the words of Mr. Justice Holmes, "True liberty of contract can begin only where equality of bargaining power begins."

The change in the status of the doctor since July 5, 1948, has not only altered but increased the problems of the profession. Many doctors, for reasons which I can well appreciate, refuse to consider themselves as "workmen" or "employees." They still feel that they are independent contractors. I would respectfully remind them and Sir Valentine Holmes, K.C., that *employed and employment* are defined in the National Insurance Act in Section 1 (2) and in Section 78, and include trade, business, profession, office, or vocation. A person who is gainfully

occupied for the purposes of National Insurance is one who is engaged in any trade, business, profession, office, or vocation, and is wholly or substantially dependent thereon for a livelihood. "Self-employed" persons include small traders and all professional persons, unless, though qualified, they are paid a salary or other remuneration under a contract of service.

The Minister of National Insurance has designated general practitioners as "self-employed," yet has ruled that specialists in contract with regional hospital boards who are engaged for more than half their time in their appointment under one board are to be regarded as "employed" persons, but that those who are engaged for less than half their time under one board are regarded as "self-employed"—a complete lack of uniformity and contrary to the definitions in Section 1 (2) and in Section 78 of the National Insurance Act. Although the Minister of National Insurance designates some of us as "self-employed" we are by virtue of the above-mentioned Sections "employed" persons because of our salaries, remuneration and emoluments on which we are wholly or substantially now dependent for a livelihood.

I submit, therefore, with some respect that the arguments expressed by Sir Valentine Holmes, K.C., on points (2) and (3) in his further and fuller Opinion published in the *Supplement* of April 2 (p. 171) are not cogent because they are based on incorrect assumptions.

With regard to his point (1), that he does not think that doctors are employed in "trade or industry," I would draw attention to the words of Lord Wright in *National Association of Local Government Officers v. Bolton Corporation*, 1943, A.C. (at pp. 184, 185). "'Trade' is, not only in the etymological or dictionary sense, but in legal usage, a term of the widest scope. It is connected originally with the word 'tread' and indicates a way of life or occupation. In ordinary usage it may mean the occupation of a small shopkeeper equally with that of a commercial magnate. It may also mean a skilled craft. It is true that it is often used in contrast with a profession. A professional worker would not ordinarily be called a tradesman, but the word 'trade' is used in the widest application in the appellation 'trade unions.' Professions have their trade unions. . . . From another point of view it may be said that every person who seeks to dispose of his services is a trader in that respect." And to cite Lord Simon in the same judgment at p. 176, "If there can be a 'trade union' to which higher grade officers of a municipal corporation can belong, it does not seem an impossible use of language to say that a dispute concerning their conditions of service may be a trade dispute." The same will apply to a trade union of doctors.

Finally, Sir, I would emphasize that I do not regard trade unionism as "political." Many of the conservative "white collar" trade unions contain a much higher percentage of Conservatives than of the two other parties. I am neither a rigid Tory nor an unbending Socialist. I am interested in trade unionism because my Liberal principles urge me to strive for a higher standard of living and more tolerable working conditions for the doctors in return for the truly efficient and arduous service rendered by them since the inception of the National Health Service Act.—I am, etc.,

London, W.8.

J. ARTHUR GORSKY.

POINTS FROM LETTERS

Graduated Capitation Fee

Dr. D. M. O'CONNOR (Launceston, Cornwall) writes: How does Dr. Bamford calculate (*Supplement*, March 19, p. 157) that on a fixed capitation fee "more the work, more the pay"? As things are at present the plausible doctor is at least as well rewarded as the conscientious. . . . I might be classified by Dr. Bamford as either "lazy" or "bad" or both, but I find that 2,250 names on my list in a partly rural practice give me all the work I can possibly do (I have averaged over twenty visits on the last six Sundays). . . .

Dr. QUENTIN EVANS (Herne Bay, Kent) writes: I was very glad to see the letter of Dr. J. W. O. Holmes (*Supplement*, March 26, p. 164), with which I fully agree. There can be no question that some doctors are quite capable of giving efficient medical attention to a large list. With a properly loaded mileage fund, or other means for compensating sparse areas, there seems no justification whatsoever for a tapering capitation fee.

Meetings of Branches and Divisions

DENBIGH AND FLINT DIVISION

At a meeting of the Division on Feb. 3 Professor Wilfrid Gaisford lectured on "Treatment of Some Common Disorders in Infancy." He said that it should always be their aim to keep infants out of hospital if possible. The risks of sending an infant into hospital—at least into most hospitals—were much greater than was generally realized.

Immediately after birth an infant should cry lustily and be a healthy pink colour. If he remained blue, one must clear his airway and give him oxygen. But if he was born white and did not cry, the position was very different. If the delivery had been difficult the condition was probably due to shock and damage to the respiratory centre. The chief points in treatment were: (1) The greatest gentleness in manipulation; (2) immediate warmth; (3) oxygen; (4) head and shoulders to be raised (having made sure the airway was clear of mucus and liquor). If the cause was haemorrhage the infant would usually die. But it might be only severe oedema, which was remediable. Cerebral dehydration was best accomplished by hypertonic rectal saline or 0.5 ml. 50% mag. sulph. intramuscularly. Phenobarbitone gr. 1/8 or 1/6 might be given if there was restlessness or twitching, and the infant should be kept undisturbed in complete quiet in the dark.

Pallor might occasionally be due to blood loss, an occult haemorrhage from rupture of placental vessels—the so-called "vasa praevia." In that case the mucous membranes were also obviously bloodless and the immediate and urgent necessity was for blood. The anaemia gravis resulting from blood destruction in the infant of an Rh-negative mother did not usually become pronounced for a couple of days, but might be present at birth in severe cases. The differentiation from the anaemia due to blood loss was made by the almost certain presence of an enlarged spleen in the Rhesus baby—and, of course, the possibility should have been known beforehand by Rh testing during the antenatal period, which should be done as a routine in every primigravida.

With regard to the feeding of premature infants, there was a die-hard superstition that unless they were given breast milk they would not thrive. That was not true. The ideal food for premature babies was undoubtedly premature milk—i.e., colostrum, with its high protein and mineral content and low fat. The institution of a "colostrum bank" for premature babies might be impracticable but would be very valuable. In the meantime they could do well on artificial milk formulas until they reached the weight of a normal infant. From then on breast milk was the ideal food.

Vomiting in the first few hours of life was quite a natural procedure, particularly if much fluid had been swallowed during the birth process. But if vomiting occurred after three or four consecutive feeds and was accompanied by excessive mucus and by cyanosis, then a congenital abnormality should immediately be suspected. To-day, with the advances that have been made in thoracic surgery, there was a reasonable chance of survival in the commoner abnormalities. Any infant showing such symptoms after feeding should be sent to hospital forthwith. Vomiting continuing from the second day onwards might be a sign of cerebral trauma. If bile-stained and projectile vomiting occurred, duodenal stenosis was likely. Pyloric stenosis did not occur at this age, although it was commonly called "congenital."

Haematemesis, like melaena, might be true or spurious. In each case the spurious preceded the true—in haematemesis by two or three days and in melaena by 12-24 hours. The spurious was due to swallowed blood, and the true to the physiological hypoprothrombinemia which occurred between the second and fourth day after birth, before there had been time for vitamin K to be synthesized in the infant's gut. Vitamin P might also be implicated, for there was an undoubted seasonal incidence in these haemorrhagic diseases of the newborn. There were, in addition, other causes of haemorrhage.

The cause of diarrhoea varied in different epidemics. Some were staphylococcal, some due to *Giles's bacillus* (a non-motile form of *Bact. coli*), and some possibly due to a virus. Almost always these organisms were penicillin- and sulphonamide-resistant, but many were streptomycin-sensitive.

There were four obvious points of attack for infections in the newborn—the eyes, the skin, the upper respiratory tract, and the umbilicus. The most important was the upper respiratory tract. The commonest source of infection was the oro-pharynx. A parent or relative—or even the doctor—with a cold might be the infective agent. As breathing was entirely nasal at that age blocking of the airway made suckling difficult. Prevention was obviously the remedy but when the infection had occurred nasal instillation of 0.5% ephedrine about 10 minutes before feeds might relieve the congestion sufficiently to enable the feed to be taken in comparative comfort. Occasionally a small length of rubber catheter might have to be passed into each nostril to secure an airway. There was no evidence that sulphonamides or penicillin were advantageous. Fingers, swabs, and gauze should never be put into an infant's mouth to clean it. A sip of water after each feed was all that was necessary to ensure cleanliness.

INFANCY

Excessive crying attracted most attention. Most of the infants were in good condition. The estimate of the parents' characters would be helpful. Screaming from pain was usually recognizable, and a napkin pin transfixing the penis was not likely to go long unremedied. Definite association with micturition was a clear pointer. Acute otitis did not usually cause screaming in infants. It was the persistent grizzler with intermittent crying bouts, or the continued screamer that he was talking about. The commonest cause was colic, and the commonest cause of colic was underfeeding, resulting in the swallowing of wind. All mothers were told to "burp" their babies during and after a feed but not before. That was an omission. The stomach should be cleared of gas as far as possible before the feed was begun. An infant had an appetite which varied physiologically within wide limits. Why should an infant be fed every 3 or 4 hours and, in the case of the artificially fed, be limited to, or forced to take the particular quantity described?

Infants on the breast or bottle would do better if allowed to select the volume of their feeds and the intervals between feeds—with two provisos: (1) the mother must be intelligent; (2) if a cow's-milk formula was used, it must be properly balanced.

The only practical differential diagnosis of pyloric stenosis was pylorospasm. There was a difference in the general appearance of the child. One with a spasm tended to be gaining weight, although perhaps slowly, and would have good faecal stools. The true stenosis showed (a) constipation, or hunger diarrhoea, and (b) oliguria. If in doubt, the best treatment was phenobarbitone gr. 1/8-1/6 according to weight given a quarter of an hour before feeds. It would not improve in 48 hours.

If there was no improvement in 48 hours with visible gastric peristalsis, then operation. But the infant should be removed from hospital after 48 hours, or 72 at the most. Nothing was more depressing than to operate on an infant, only to lose him from gastro-enteritis or pneumonia caught in hospital.

It was often not realized how much sugar an infant could take. It was easily digested, provided readily available energy, and promoted peristalsis by its fermentation in the gut and thereby aided evacuation. The important thing was the ratio of carbohydrate to protein. In cow's-milk feeds the optimal proportion was attained when one part of sugar was added to 12 parts of whole milk. Bringing the sugar up to this level would often cure constipation in infancy. In the case of breast-fed babies constipation might be a sign of underfeeding.

Failure to thrive was a great source of worry to parents and doctors alike. Having excluded organic and constitutional disease the chief line of approach was the "self-selection" method of feeding. Such infants were not suitable for admission to hospital, and many began to improve as soon as they were allowed to assert their individuality as regards feeding. Of equal importance was the avoiding of emulsions and oily preparations, which tended to promote anorexia.

Finally Professor Gaisford pleaded for the home nursing of infants with acute infections such as bronchopneumonia and meningitis—especially the latter. Sulphonamides and penicillin given haphazardly could do a lot of damage. One really large dose would often succeed, and—particularly in meningitis—the less the spinal canal was interfered with the quicker the infant got better. The general condition of the infant was the clue to progress, not the alterations in cells and protein in his cerebrospinal fluid, and not even his temperature. That might fall gradually over a period of days without treatment. Injections given 3- or 4-hourly were unpleasant in childhood. Their aim should be to deal a shattering blow to the infecting organism and then to leave the natural powers of resistance to take over, which, if they were given a chance, they would usually do.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

LONDON SATURDAY APRIL 23 1949

WOMEN WAR CAPTIVES IN RUSSIA

BY

R. F. A. DEAN, M.R.C.S., L.R.C.P.

(From the Medical Research Council Unit, Wuppertal, B.A.O.R., and Department of Experimental Medicine, Cambridge University)

In August, 1948, 24 women who had recently been released from camps in Russia were admitted to one of the hospitals in the British zone of Germany which received returning prisoners of war in need of medical care. They were, on the whole, in very good clinical condition, and this seemed remarkable when considered in relation to the known or generally believed stories of hardships of life in Russia. It was therefore decided to obtain from some of the women careful and detailed accounts of their experiences.

In order that the accounts might be comparable and more easily managed, a questionnaire was drawn up and was followed as closely as the women's talent for diversion allowed. The account now presented was put together from the replies received. So far as possible it is an exact record of the replies, and comment has been excluded.

Six women, whose ages ranged from 21 to 37, were chosen for the questioning. They were all women who had come to the British zone as *Ost-Flüchtlinge*—that is, they no longer had any homes in any of the four German zones. They were questioned in complete privacy by a woman doctor who spoke German and English fluently, and they gave the accounts of their lives in Russia with perfect willingness and, so far as could be judged, without exaggeration of their hardships or pleasures. They appeared to be excellent witnesses, and their statements, made without hesitation and quite spontaneously, bore the ring of truth. The frequency with which they corroborated each other's stories was extraordinary. Two of the women (Margret and Ida) were, in fact, discovered to have been inmates of the same camp by the exactness of their descriptions of camp conditions.

The Women, and How They were Taken into Captivity

The six women were Ida and Elli, both aged 21; Hanna, aged 24; Margret, aged 26; Agnes, aged 32; and Emma, aged 37. All six came from the eastern portion of Germany, which is now partly Russian, partly Polish. Hanna came from the south (Silesia) and all the others from the north (Pomerania; East and West Prussia). They had all lived in country districts, and all except Hanna, who worked in an office, were doing housework and farm-work in their own homes. The two eldest women were married. Agnes had a daughter aged 12, but Emma had no children. Agnes's husband had to join up in 1942, and she then went home to her mother; Emma's husband, who was also a soldier, was reported missing in October, 1944.

The villages in which the women were living were occupied by Russian troops in February and March, 1945; and shortly after the occupation Elli, Hanna, and

Margret were visited by soldiers, who told them to go away with them immediately for three days' work. Elli, who had been expecting a summons of this kind, was wearing extra clothing and was told to take a blanket with her. Hanna was caught when on a visit to the neighbouring town. There she was questioned extensively, then taken to her home and told to dress in her warmest clothes. Margret had a rucksack, in which she packed some warm garments. Ida was taken from her home and told she must work for four months, and she also was allowed to pack a bag with some clothing. Agnes would have been taken from her home in the same way, but the Russians who came for her were apparently unnerved by the screams of the children who saw her going. Next day, however, while she was at some compulsory work of clearing away rubble, she was arrested with the women who were working with her and given no chance to go home. Emma hid in her mother's home for fourteen days after the Russians came, and then went with other women to the Russian commandant to ask for work, which they hoped might provide them with some sort of protection. They were set to mind horses. After a fortnight of this Emma was taken to the next village to clear away rubble. She could send no word home, and did not, in fact, see her home again.

It appears that to some extent age determined the choice of prisoner. Thus Elli and her sister aged 15, and four girls of similar ages, were taken together; Margret's father (49), her sister (20), and her brother (18) were taken with Margret herself, but her two sisters (13 and 7) and her mother were left. There was at this stage no examination to determine fitness for work. All the six women knew of cases of women who were pregnant when they were taken off. One gave birth on the journey to Russia, and she and her child died. Many others whose children were born later were repatriated after a short time.

Conditions on the Journey

It was usual for the women to be collected in cellars or other safe places. When the numbers were sufficient they were either marched or taken by lorry to a railway centre; a period of from seven to 14 days was usually occupied in these preliminaries, and all the six women said that it was physically the most exhausting of their experiences and the most severe mental strain. There was a widespread fear at this time, which seems to have been to some extent justified, that they were in constant danger of rape. There was no actual corporal punishment on the march, but the guards were very strict, urging the prisoners on with their rifle butts. Some of the women had to

long distances. For instance, Elli had a very hard journey. Her party was forced to walk for the first two days, and many of the women broke down and were left by the wayside, and Elli does not know their fate. The night of the second day was passed at a farm, where they were offered good food but were too exhausted to eat it. The next day the party were lodged with about 2,000 other women in a bank building, where they were kept for two days. On the third day they set out on a journey in which they walked 100 km. in three days. Many fell out, and the officer in charge said: "If you cannot get along, stay here and go 'kaput'."

At the railway centres it seems to have been usual to provide washing facilities, and something was done to eliminate lice. For the actual railway journey into Russia the women were packed into cattle-trucks, about 80 in one truck. Sleep was very difficult, and if one woman wanted to lie down, other women had to stand. For toilet purposes there was a hole in the floor of the truck. Washing was impossible, and the food was very inadequate; a little bread was distributed three times a day, and each woman had one spoonful of sugar a day. All six women agreed that the lack of water was, however, the worst of their deprivations, and Elli and Emma said that their parties were actually screaming for it. One girl aged 18 in Elli's truck died after having diarrhoea. Elli thought that about 40 to 50 of the 2,000 women in her transport died on the journey. The train journeys lasted from two to four weeks; Ida and Hanna had the shortest journeys, and Elli the longest.

One woman, Hanna, ended her journey in the Caucasus, and the other women went to the Urals. The women all remained in these districts, but they were moved from camp to camp several times until they finally settled in camps where they stayed for periods lasting up to two years. In the Urals the variations of temperature between summer and winter were extreme, with cold in winter down to minus 50° C.; but in the Caucasus the climate was more temperate. The camp conditions in the first few months were obviously very bad. The camps usually consisted of collections of wooden huts, which were in a filthy condition and overcrowded. Many deaths occurred in these first months; Elli said that 18 of the prisoners with her died in one day, and she and the other women believe that the total number of women prisoners was almost halved by death by the end of 1945. The chief causes of death were typhoid and similar gastro-intestinal illnesses, and "water," which was apparently a generic term for swellings of feet, hands, and face.

The Work and How it was Done

The first medical examination was made by Russian doctors, or by German doctors under Russian supervision, within three to four weeks of arrival. The women were classified according to their capacity to work, but the examination consisted merely of an inspection. There was no thorough investigation. They were put in four groups: Group I were the fittest, and Groups II and III were less fit but still capable of work, whereas those in the fourth group, called "O.K." (*ohne Kraft*), were unfit for anything except cleaning and other chores in the camp. Margret and Emma were classified at this preliminary examination as "O.K." and the others as Group II.

Margret and Emma had no set work for the first six months. Agnes was put to work in a lime-kiln, and her job was to fill trucks with the lime. She said it was very hard work and the lime made her eyes smart; other women had lime burns. Ida, and Margaret as soon as she was well enough to be put in Group III, worked in a peat-

field, carrying the turves, stacking them, and loading them into trucks. The actual cutting of the peat was usually done by men or by the fittest women. Elli worked in a coal mine 275 metres below the surface. There she had to drag pit-props a distance of about 700 metres. The mine tunnels were only about 1.5 metres high, so that she had to walk in a bent position. For a short time she had to shovel coal. Hanna was not so specific in her account of her work. She was in a labour camp where the women were called on to do all kinds of work, such as helping to build roads and houses, and for a short time she worked in a silver mine. In July, 1945, Emma was put to work in a tile factory. For the first month she had to lay down boards for the tiles to dry on, but for the next six months she had to clear dust from the chambers in which the tiles were baked. These chambers were very hot and dusty. Afterwards she went back to carrying the boards.

All the women stated that a specific amount of work known as the "norm" had to be done each day. Each group had a different "norm," which was fixed according to the fitness for work, and Ida gave the following example. In her peat-field the "norm" for a Group II worker was to clear eight rows, each 200 paces in length, and this was to be done in eight hours. Group III had only six rows to clear, and this was expected to take six hours. Both groups were therefore thought capable of doing the same amount of work per hour. If the "norm" was not completed within the set time the women had to go on until the rows were finished. If for any reason other than obvious illness the women failed to complete the "norm" they were liable to be given solitary confinement for one to three days. There was no corporal punishment.

All had one free day each week, but some had to do camp cleaning on this day. Although the women longered not to work they did not actually refuse, the reason being perhaps that, as will be shown later, in most cases good work guaranteed better food. All the women said that they were worked to their utmost capacity.

Payment for work was sometimes made in money, sometimes in goods. If, as in Elli's camp, they were paid in money they had to buy all their own food, but the earnings were enough to enable the best workers to buy as much as they wanted. The average worker or sick woman earned less and managed to buy only the food offered in the camp kitchen. In most camps it seems to have been a rule not to pay the women in money but to set the "norm" as the minimum amount of work which guaranteed free food. Extra work—graded in percentage above the "norm"—was rewarded sometimes by money payment and sometimes by material for garments.

The Food in the Camps

There was general agreement that the food was of very poor quality and inadequate in quantity during 1945 and 1946, but that it improved to some extent later. Despite this improvement all the six women except Elli said that they were always hungry. They usually had three meals a day, but Hanna and Emma had only two. The number and time of Emma's meals were determined by the fact that she had to work for eight hours without a break. Meals were served in her camp only at 6 a.m., 12 noon, and 6 p.m. The staple items of diet were cabbage soup, bread, and *Brei*, which was a kind of soup made principally from cereal, but Emma received *Brei* only if her work was considered good.

On the average the women seem to have been given 600 to 800 g. of bread per day; the quality of the bread was, however, said to have been very poor. As a rule 0.5 kg. of sugar was issued once a month, but many months

ssed without it. Ida said that the younger women often ate the whole pound straight off. She also ate stinging nettle, which she had gathered on her way to work. They were eaten raw after she had rubbed them in her hands so that they might not sting her tongue. All the women agreed that the food was not adequate for the work they were expected to do. The meals never satisfied them, and Anna said that she thought no one could have survived on the basic camp rations. In her camp extra food could be bought. In 1946 she sold her coat for 520 roubles to a Russian civilian and used the money to buy potatoes and some fruit. She said they were always looking through their belongings to see what they could turn into food.

In Margret's camp extra food also had to be bought, but only the men who were fellow prisoners were paid. The women were able to get some of the men's money by doing various jobs for them. Emma in the last two months was able to earn 930 g. of bread a day because, although she was in Group III, her output of work was that expected of a woman in Group II. This was her only way of getting extra food. Agnes could not get food for extra work, but managed to do some needlework and knitting for Russian civilians, who gave her potatoes and milk in exchange. Elli had a different story because her earnings were from 30 to 50 roubles a day and her basic food requirements only cost about half this amount. Bread cost her 3 roubles and 10 kopeks for 1 kg., and a small portion of *Brei* 10-90 kopeks. She was in the comparatively fortunate position of being able to supplement her diet out of her income with such extras as milk, but that cost 10 roubles for 0.5 litre. Meat at 80 roubles for 0.5 kg. was too expensive for her to buy.

The women were asked if they craved for any particular food. Elli said that she had no cravings, as she could have bought anything if she had wanted to pay for it. Ida longed for potatoes and meat—something “*kräftig*”; Hanna for potatoes and something sweet. Emma wanted milk and butter, Margret and Agnes wanted “proper” whole potatoes, *Brötchen mit Wurst*, and cake.

Living Conditions, Medical Care, and Illness

The permanent camps consisted of a collection of one or four wooden huts set in a compound and surrounded by wire fence. In the larger camps the compound was about the size of a football ground. There was only one entrance to the camp, which was guarded. The number of women in each camp varied widely, from 80 in Hanna's camp to 1,000 in Emma's. In each camp there were usually a small number of German men who were civilian internees and who had been taken from their homes at the same time as the women. Twenty to thirty women occupied one room, spending their free time there during the day and sleeping there in beds which consisted of double-tiered wooden frames with straw mattresses. All the six women except Agnes had blankets, but she had to use her coat instead. Ida and Emma complained about the bugs, which disturbed their sleep. There was no possibility of any kind of privacy in the camp. Although washing facilities were more or less primitive, and soap was scarce, all the women agreed that they could maintain a reasonable standard of cleanliness. Emma, Margret, and Ida said that they were examined for lice once a week but that hair was shaved only if lice were actually found.

All but Agnes said there was a monthly sick parade, which was held by a German or Russian doctor. It was merely an inspection with the object of reclassification if necessary. In most camps a doctor was available to see acute cases and to decide if an illness was severe enough to prevent the woman from working. Elli said that to be

certified as sick there must be fever over 37.5° C., furunculosis, or a swollen face. In Ida's camp there were once considered to be too many women with temperatures over 37.5° C., and so the critical temperature was raised to 37.8° C.

In all except the smallest camps a room was set apart for women who were ill, and they were looked after by a nurse—usually a German girl, who did this instead of other work. This room was only for women who were really ill and was not available for those who merely needed rest. Severe cases were sent to the local civilian hospital or to the hospital of a neighbouring camp centre. Ida unfortunately had diphtheria in her first year. She was sent to the local Russian civilian hospital and was treated like the other Russian patients. She stayed there for four weeks, and was then sent back to camp, where she had to start work again immediately, although she complained of pains and stiffness in her legs, of water running out of her nose when she drank, and of difficulty with her speech. After five days' work she was seen by the Russian doctor, who put her on light work in the camp kitchen for three months. Her condition got worse and worse, and eventually she was sent back to the civilian hospital. There she rested for four weeks, and was then given some kind of light therapy, and her condition began to improve. The most common illnesses seen in the camps were typhoid and diarrhoea, malaria, and furunculosis. Tuberculosis and other lung diseases do not seem to have been especially prevalent. The six women attributed most of the illness to bad food, but Agnes said that much of the illness in her camp was due to the work with lime.

Nearly all the deaths of which the women had any knowledge occurred within the first year, and were attributed chiefly to the bad conditions. Even so, Elli thought that the women who died were those who let themselves go too much, who were very depressed and did not put up a fight. Some women who were beyond caring drank stagnant or polluted water and became ill and died. Some women actually went mad. Hanna told a gruesome story of the first months of her imprisonment, when food was very scanty and large numbers died. She thought that, in proportion to the total numbers, more men died than women. During these first months the whole camp was practically a hospital. Fatigue parties took out the corpses at night to bury them in mass graves. Wolves came and dug up the corpses and ate them, and Hanna was with a party which was sent out to rebury the bodies. Her uncle was one of those who died in her camp.

The six women were asked what illnesses they themselves had suffered from. Margret, Agnes, Hanna, and Emma all had oedema of the legs in varying degrees. Margret had it when she arrived in Russia, and said she noticed it more often on her days of rest than on working days. Her hands and face were also swollen. She and Agnes also had polyuria. As previously mentioned, Ida had diphtheria, and Elli and Hanna had malaria. Ida eventually owed her release to a periodontal cyst which increased steadily in size. The Russian doctors preferred to send her home rather than operate on her. Hanna had typhoid and what she believed to be nephritis. She, Ida, and Margret all had lice, but none of them had typhus. Among minor ailments which were not referred to as illness were very painful pins-and-needles in Elli's hands, Margret's breathlessness, palpitations, and hot flushes, and Agnes's giddiness. Elli, who had started to develop a goitre when she was 16, found that it almost disappeared when she was in Russia. It seemed to enlarge as her general condition improved.

Unfortunately only Elli was able to keep any record of her weight. She weighed 51.5 kg. in 1944, and only 41 kg. in 1947. She weighed 51 kg. on her return in 1948. Hanna, who in 1947 was able to weigh herself on the potato scales, thought that by then she had lost about 23 kg. from her 63 kg. in 1944. Ida thought that she was at one time about 7 kg. under her normal weight, and Margret and Emma merely said that they got very thin.

Lack of clothing was not blamed as a cause of illness. All six women were allowed to keep what clothing they had of their own, and in addition to this were given padded clothing for the winter. The materials they earned by extra work, and other materials and wool which were obtained by barter or purchase, were made up during leisure hours, and it was evident that a great deal of care and trouble were expended on the making of the garments. The women brought back with them to Germany underclothing, blouses, and cardigans, all of which were very well made and proved the interest that was taken in the work. In the early days before needles and other sewing materials were available the men in one camp made knitting-needles from pieces of wire. Skill in needlework was made to serve a double purpose, as some Russian civilians were willing to pay with food for knitting or sewing.

The walk to work and the work itself precluded any idea of physical activity in leisure hours. The women were usually confined to the barrack precincts, but in the last year or so some degree of freedom was allowed. Elli, Ida, and Margret could then go to the nearby village alone, and Agnes was allowed to go into the woods sometimes to gather mushrooms and berries on her free day. In Ida's camp there was dancing once a week to music played on home-made instruments, and in Emma's camp there was even a club with a wireless set and occasionally a film show. There was a reading-room in this club and German newspapers. Agnes said that there were no books in her camp; Margret said books were to be had, but she was not interested in them. The reaction of the six women to imprisonment varied according to their temperament, and most of them appeared to have accepted their fate in a way which, when they were questioned, was expressed by a shrug of the shoulders accompanied by some remark

such as: "We had to be contented"; "We did not worry much—it was no use"; or "Was sollten wir machen?"

The girls in Elli's camp were perhaps less apathetic. They were living under more normal conditions, because they were paid for their work, and although they had to pay for their own food they could improve their condition by other purchases. This enabled them to maintain an interest in life, although, as Elli said, they had almost given up hope of ever returning home. They had ceased to worry about it, and disbelieved the rumours of repatriation. Hanna said she always thought, "I must get home," but she tried to be cheerful and to keep in good spirits because she realized that this gave her the best chance of survival. Agnes knew of one woman, aged 35, who tried to escape from Russia and reached Moscow before she was caught. She was said to have been sent to Siberia for fifteen years. The other women knew of no attempts at escape made by women, and laughed at the idea. In some camps a few children had been born, and Ida said that she liked to play with them in her leisure hours. None of the other women seems to have found any outlet for her maternal feelings, but no comment was made which indicated an appreciation of this lack.

The first chance of communication with relations came early in 1946, when most of the women were able to send postcards. Elli said that even the privilege of sending the first postcard was held out as an inducement for the best work. Ida and Elli were the first of the six to receive news from home, which they did in June and September, 1947, but Emma did not hear from her husband until March, 1948. Hanna had no news at all until she reached the British zone; the three other women had postcards from relations in the first three months of 1948. Margret and Agnes both said that not knowing what had happened to their families was almost the worst of their trials. Incidentally, Ida felt that the lack of freedom was the hardest to bear—even worse than the bad food, which was the chief complaint of the other women.

Menstruation and Sexual Feelings

Before their captivity all the women had menstruated regularly at intervals of 25–31 days, and the periods were normal. They all stopped menstruating in Russia, and the accounts are summarized in the accompanying Table. Or

Table Summarizing the Menstrual History

Name	Age of Menarche	Age when Taken Prisoner	Date of Last Period	Circumstances of Last Period	Date and Circumstances of Reappearance of Menstruation	Comments
Ida	17	18	April, 1945	En route to railway base	August, 1948, in Germany	No periods while she was in Russia, but a heavy yellowish discharge every 4 weeks. Headaches and "sexual feelings" in the head at the same time as the discharge. She thought other girls had similar symptoms
Elli	14	18	April, 1945	En route to Russia in railway truck	January, 1946, while working on a collective farm. Periods regular for 3 months, then stopped when she began mine work and did not restart until 1947. Stopped again May, 1948, and restarted August, 1948, in Germany	The restart in 1947 was due, she thought, to better food she received at that time
Hanna ..	14	21	September, 1945	In hospital for typhoid and malaria	Not yet restarted	She was certain that cessation was due to bad food, as girls who worked the kitchen menstruated as long as they were getting better and eating food. She herself menstruated "as long as she had any calories in her body"
Margret ..	15	23	January, 1945	At home	Not yet restarted	
Agnes ..	15	29	April, 1945	En route in railway truck	Not yet restarted	Had headaches and backaches every four weeks
Emma ..	16	34	March, 1945	While working for Russians (minding horses) before being taken prisoner	Not yet restarted	

da and Agnes noticed anything which might have replaced or formed a part of the normal menstrual cycle.

The women were asked if they were worried by the stoppage of periods. Hanna said that she was worried, but that the doctors reassured her. Margret, Agnes, and Emma were not anxious about it, and Emma thought it was "*sehr natürlich*." Hanna and Elli thought that normal sexual desires persisted, and Elli's replies suggested that if she had found a suitable partner she might have had intercourse with him. She was the only one of the four unmarried women who admitted that she was not a virgin before captivity in Russia. Ida was on very good terms during the last year in camp with a German boy aged 18, but the friendship was of an adolescent type and did not advance to sexual intercourse.

Since their return to Germany the two married women had met their husbands and had opportunities for intercourse. Agnes, who had had a number of years of married life before the war, said that, although she was happy to be with her husband again, she was "*zu schwach*" for sexual relations. Emma, who was married (at the age of 33) while her husband was on leave from the Army and had spent only one other short leave with him, said that her relations with him after their four years of being apart were perfectly normal. Margret dismissed the subject by saying that she was too young and that she was not interested in the men in the camps.

Four of the women knew personally women in their camps who became pregnant while they were in captivity, some of the fathers being German prisoners and others Russians of German or other descent. No details of the menstrual history of the women who became pregnant could be obtained. The children were born in the local hospitals, and all the mothers were able to breast-feed their children. Pregnant women received extra food from the 10th month and during lactation, and Elli said the children in her camp looked very bonny. These pregnancies were not the results of rape. All the women agreed that the danger of rape was over as soon as they were "*verladen*" into their cattle-trucks. (The word *verladen*, which was always used by the women when talking about their train journey, is normally never used for human beings but only for cattle and goods.) All the women except Margret were able to avoid rape during the critical first weeks, and regarded this as very good fortune. Margret said she had been raped "only twice"; she did not enlarge on this statement.

The Release from Captivity

During the last year there were rumours in most of the camps that release might be near for women in Group III. Previously only women who were unfit for work had been sent home. Release, when it actually came in July, 1948, was sudden and unexpected. Margret, Agnes, Emma, and Hanna were released because they were in Group III, and Hanna said that she was lucky in that the choice was made according to the classification of March, 1948. She had actually since then considerably improved in health. Elli was released because she had had an accident in her mine at Christmas, 1947. She had broken her collar-bone and two ribs when she was crushed between two trucks. Since then she had been on lighter work and made a good recovery. Ida, who was a Group I worker in the last two years, was sent home because of her dental cyst.

All the women gave a similar account of their return journey. Although they again travelled in cattle-trucks until they reached the border of the Russian zone at Frankfort-on-Oder, the conditions were very much better than on the outward journey, and there were no complaints of ill-treatment. They went from Frankfort-on-Oder to

Göttingen, where they were medically examined. The very great majority of all the women repatriated at this time were dismissed from hospital care or left hospital at Göttingen of their own accord to join relations in the western zones. Twenty-four women who preferred to stay under medical care after meeting their relations were sent to another hospital at the beginning of August, 1948, and the six women questioned belonged to this party.

Finally all the six women were asked what their plans were for the future. Margret hoped that when she was fully recovered she would be able to join her mother, who had come to the British zone and was trying to build up a home again in Hilden, near Düsseldorf. Ida expected to join her mother, now in a village near Krefeld, and had made inquiries about work in a factory where her brother was working. Hanna planned to keep house for her uncle and cousin in the British zone. Elli's family was widely scattered, and she could not decide what she would do. Her mother was still in her old home in Pomerania, and her father, who had been a prisoner of war in England, was working for a farmer in the Ruhr Valley. She had other relations near Münster and she might go to them. The two married women, Agnes and Emma, intended to join their husbands, who were trying to establish themselves in the British zone. They would leave hospital as soon as they felt completely well.

Summary

An account is given of the experiences of six German women who were taken into captivity in Russia. This account was compiled from the information they gave after they had returned to Germany. Great hardships were endured at first, but conditions gradually improved, and the women were in good clinical state on their return.

Menstruation ceased soon after the women were captured, and five of them had amenorrhoea for nearly three years.

P.T.A.P.: THE PRESENT POSITION

BY

LEWIS B. HOLT, M.Sc.

The Wright-Fleming Institute of Microbiology, St. Mary's Hospital, W.2

AND

GUY BOUSFIELD, M.D.

In the prophylaxis of diphtheria A.P.T. has certain drawbacks: it is not constant in its composition and, especially in adults, there may be unpleasant reactions. One of us (L.B.H.), working in the Wright-Fleming Institute of Microbiology, produced a purified diphtheria toxoid which instead of being precipitated by alum was adsorbed on to pure aluminium phosphate—a more suitable compound. To this prophylactic he gave the name P.T.A.P. (signifying *Purified Toxoid precipitated by Aluminium Phosphate*).

In November, 1944, it was decided that the results obtained in guinea-pigs with this new diphtheria prophylactic justified field trials (Holt, 1947). At that time we appreciated that numerous important problems arose in diphtheria prophylaxis regarding which there was very little accurate knowledge. These included: (a) the route of choice for inoculations—subcutaneous or intramuscular; (b) the dose of toxoid (Lf units) administered as adsorbed toxoid for the satisfactory mass immunization of children; and (c) the optimal amount of mineral carrier (AIPO₃) to employ. The new method gave us complete control of the composition of the prophylactic and therefore promised

that these questions could be answered with a measure of reliability not previously obtainable.

In the preliminary trials very small amounts of aluminium phosphate carrier were employed. The results of these trials (Bousfield, 1947a) revealed two important facts: (1) that aluminium phosphate is an extremely suitable vehicle for adsorbing toxoid when used for human prophylaxis, in that local or general reactions were absent or at most trifling; and (2) that the efficiency of the prophylactic, as judged by the Schick conversion rate (S.C.R.) in young children following one inoculation, increased as the amount of phosphate was increased, but without clear-cut evidence of an optimal amount. The amounts of carrier eventually used, and with no untoward reactions, were very much greater than would be considered safe if presented as A.P.T.

As the work progressed it was found that samples of P.T.A.P. having a mineral content of 10-15 mg. AlPO_4 per ml. gave the best Schick conversion rates (dose 0.5 ml.); that this new prophylactic improved in antigenicity on storage (three months) at room temperature (Bousfield, 1947b); and that consecutive batches, chemically almost identical and of the same age, were antigenically the same (Bousfield, Duke, *et al.*, 1948).

We propose here to set forth further details showing the superiority of P.T.A.P. over A.P.T. in the immunizing of children and some further details about its constitution and use.

Uniformity of Antigenicity in Successive Batches of P.T.A.P. and A.P.T.

It has been found that successive batches of A.P.T. sometimes show disturbing variations in efficiency when tested in the field (Bousfield, 1947c).

These variations were greatly reduced by the acceptance in 1942 of more stringent provisional regulations (B.M.J., 1942). Even so, although the new regulations eliminated the grossly inferior products they did not solve the problem of variations in antigenicity. These, of course, are more readily demonstrated when the responses to single inoculations are observed (Bousfield, 1947a).

Evidence showing the degree of antigenic uniformity obtainable with P.T.A.P. has already been published (Bousfield, Duke, *et al.*, 1948), but it may be useful at this stage to recapitulate. In Table I a summary of the results already published is given together with those obtained recently from single inoculations employing six unselected batches of Government issue A.P.T. It will

TABLE I.—Uniformity, and Performance of Six Consecutive Batches of P.T.A.P.* (30 Lf and 10 mg. AlPO_4 /ml.), and of Government Issue A.P.T. (Lf>50/ml.) Dosage 0.5 ml.†, Administered Intramuscularly. Children all Schick-positive before Immunization, and Post-Schick-tested Four Weeks After a Single Inoculation.

Batch No.	Post-Schick Results							
	P.T.A.P.				A.P.T.			
	(+)	(-)	Total	S.C.R. %	(+)	(-)	Total	S.C.R. %
1	9	143	152	94.1	11	66	77	85.7
2	5	144	149	96.6	11	87	98	88.8
3	6	149	155	96.1	6	35	41	85.4
4	4	146	150	97.3	22	111	133	83.5
5	4	160	164	97.6	1	28	29	96.6
6	0	141	141	100.0	1	39	40	97.5
Total	28	883	911	96.6	52	366	418	87.5

* Redrawn from Bousfield *et al.*, 1948.

† Two and one-half times the officially recommended first dose for A.P.T.

Statistical Analysis of the Results

	χ^2	df	P
P.T.A.P.	9.284	5	<0.10
A.P.T.	8.930	5	>0.10
Comparison	44.436	1	<0.001

Namely, there is no significant heterogeneity between the six batches in either group, but P.T.A.P. is definitely superior to A.P.T.

be noted that with P.T.A.P. the Schick conversion rate varied from 94.1 to 100%, with an average of 96.6; and the rate for A.P.T. varied from 83.5 to 97.5, with an average of 87.5%. These latter figures were obtained with a dose of 0.5 ml., which is two and a half times the officially recommended first dose.

The differences among the samples of each group are not statistically significant in either case, but the difference between the results obtained with P.T.A.P. and A.P.T. is significant.

Route of Choice

It was thought of some importance to determine whether the immunity response after intramuscular injection differed from that after subcutaneous injection. To answer this question the following evidence may be taken into account: direct observations (Schick conversion rates) made at a fixed time interval on a number of subjects who had been inoculated by one or the other route; the immunity response curves over a period of time following injections by either route; and a combination of the results obtained from the above two methods.

In regard to the first method, samples of P.T.A.P. were employed containing a fixed amount of toxoid (5 Lf in 0.5 ml.) and widely different amounts of aluminium phosphate carrier. The conversion rates were determined 28 days after inoculation. The results, which are summarized in Table II and have their probit analysis depicted in the diagram, show that the intramuscular route gives a significantly better response.

TABLE II.—Comparative Antigenicity of P.T.A.P. of Varying AlPO_4 Content, when Administered Either Subcutaneously or Intramuscularly. (Toxoid Dose Constant at 5 Lf in 0.5 ml. S.C.R. Determined 28 Days After One Inoculation).

Mg. AlPO_4 Injected	Schick Conversion Rate %	
	Subcutaneous Route	Intramuscular Route
1.5	65.6 (93 cases)	87.3 (79 cases)
2.5	83.3 (54 ")	95.2 (83 ")
3.5	85.0 (100 ")	92.7 (82 ")
4.5		94.1 (85 ")
5.0	93.3 (45 ")	
5.5		92.9 (55 ")
6.5		96.4 (84 ")
7.5	91.5 (47 ")	97.4 (88 ")
	(339 cases)	(556 cases)

Statistical analysis of Comparable Groups					
Mg. AlPO_4 Injected	χ^2	df	P		
1.5 ..	10.949	1	..	<0.001	
2.5 ..	5.346	1	..	<0.05	
3.5 ..	2.605	1	..	<0.20	>0.1
7.5 ..	2.807	1	..	<0.1	>0.05
Total ..	21.707	4	..	<0.001	

Regarding the second method, no data are available concerning the time for maximal Schick conversion rate in children who had received subcutaneous inoculations either A.P.T. or P.T.A.P. It has been found in guinea-pigs, however, that when A.P.T. or P.T.A.P. is administered subcutaneously the time for maximum antitoxin response was always the same regardless of the amount of mineral carrier employed—namely, 25 to 28 days (Holt, unpublished observations). This was correlated with the time for fibrous encapsulation of the residual mass (nodule formation) to occur—namely, some 7 to 10 days.

Since the time interval for the (sterile) foreign-body reaction in the human is the same or even a little longer, seems justifiable on this point to transfer the evidence direct from the guinea-pig to the child.

When an inoculation is made intramuscularly it would seem reasonable to infer that the continuous movement of the muscle fibres would not only usefully disperse the injected particles but delay or even prevent fibrous

Probit Analysis of the Two Curves

	χ^2	df	P
Homogeneity of subcutaneous series ..	1.620	3	>0.50
Homogeneity of intramuscular series ..	2.532	5	>0.70
Parallelism between the two curves ..	1.724	1	>0.10

Namely, no significant deviation from parallelism.

Both the subcutaneous route and the intramuscular route show a linear dependence on the probit of the response (percentage of Schick negatives) with the logarithm of the dose of carrier, a result analogous to that shown by Carlinfant (1948). The two lines are parallel, and the ratio of potency of the intramuscular to the subcutaneous route is 2.6 with 95% fiducial limits of 1.4 and 5.0; therefore the intramuscular route is definitely superior to the subcutaneous route.

encapsulation. Should this occur the antitoxin response curve to moderately large or large doses of P.T.A.P. or A.P.T. should show a peak value later than 28 days after injection. This was in fact found to be the case.

Three sets of figures are available on this point. The Schick conversion rates after a period of time were observed in children who had received intramuscular inoculations of 0.1 ml. A.P.T. (Lf 50), 0.5 ml. P.T.A.P. (Lf 200, 5 mg. AlPO_4 /ml.), and 0.5 ml. P.T.A.P. (Lf 190, 8 mg. AlPO_4 /ml.). In the case of the very small dose of A.P.T. the conversion rate showed a peak value at the sixth week, and in both cases of P.T.A.P.—where much more carrier was employed—the Schick conversion rate was still rising at the end of twelve weeks (Bousfield, 1947c). These observations show that conversion rates obtained four weeks after an intramuscular injection of P.T.A.P. would have been higher had the tests been carried out at a later date.

This conclusion, now referred back to Table II, means that in the case of the subcutaneous route the conversion rates found represent maximal ones and those for the intramuscular route submaximal.

From all these considerations it is concluded that the intramuscular inoculation of P.T.A.P. containing reasonably large amounts of mineral carrier results in a more complete utilization of the prophylactic than that following subcutaneous inoculation, with its early fibrous encapsulation of much of the material injected.

Optimal Amount of Mineral Carrier

In determining the optimal amount of mineral carrier to employ in young children it is not possible to substitute any animal for the child, and it would be unwise in our present state of knowledge to rely too much on investigations based on a weight-for-weight basis between animal and child. The results already published (Bousfield, 1947a) clearly demonstrate the great part played by the amount of carrier inoculated, and reveal that the best conversion rates are obtained with samples of P.T.A.P. containing 10–15 mg. AlPO_4 per ml. (see Table II). But to be able to say definitely that 15 mg. is better than 10 mg., or vice versa, involves two serious difficulties, as the percentage differences involved are very small. These difficulties are: (a) the rapidly increasing dose of antigen required to immunize the residual less responsive members of a population, and (b) because of this, the necessity for studying really large numbers of cases, if it is sought statistically to substantiate any conclusion drawn, when Schick conversion values greater than 90% are achieved.

With the limitations indicated above borne in mind, the evidence shown in Table VI strongly indicates but does not conclusively prove that P.T.A.P. containing 10 mg. AlPO_4 per ml. is better than an antigen containing 15 mg.

Essential Lf Dosage

In order to answer this problem it was considered necessary to use a rather longer time interval between inoculation and the post-Schick test. It was therefore decided to determine the Schick conversion rate three months after a single intramuscular inoculation of samples of P.T.A.P. each containing 15 mg. AlPO_4 /ml. and different amounts of purified toxoid. The figures obtained from a preliminary test were as shown in Table III.

TABLE III—Schick Results

Toxoid Injected (Lf)	Three Months After One Intramuscular Injection of 0.5 ml.		
	(-)	(+)	S.C.R. (%)
5	114	6	95
10	123	2	98.4
15	118	5	96
20	124	1	99.2
30	120	4	96.7
Total ..	599	18	97

$$\chi^2 (5 \text{ Lf/the rest}) = 1.8, P = 0.2.$$

These results do not show any statistically significant differences.

This experiment was repeated. For the more recent trials, two similar series of preparations were used, and observations were made at three time intervals—three, six, and fifteen months after injection.

It is clear from the results shown in Table IV that, using a dose of 7.5 mg. of AlPO_4 , the same excellent responses were obtained with amounts of toxoid varying from 10 to 30 Lf. Even with 5 Lf of toxoid the response was not appreciably lowered.

Amounts of toxoid as low as 10 Lf/ml. gave results equally as good as those obtained from the amounts prescribed by the T.S.A. Regulations (50 Lf/ml.). It seems, therefore, that much of the toxoid demanded by the present regulations is wasted when used in P.T.A.P. This is a matter of no small importance economically when toxoid of the quality described is used.

Another point of importance arising from these findings is the persistence of the immunity induced by one dose of P.T.A.P., which suggests that we may in fact be in sight of a single-injection prophylactic against diphtheria.

TABLE IV.—Schick Conversion Rate after One Inoculation of 7.5 mg. of AlPO_4 , with Varying Amounts of Purified Toxoid (Children Aged 1 Year at Time of Inoculation)

Lf Injected	Schick Failure Rate %		
	Material E.3061		
	After 3 Months	After 6 Months	After 15 Months*
5	5.0 (120)	4.0 (50)	4.08 (47)
10	1.6 (125)	4.1 (49)	4.08 (49)
15	4.06 (125)	1.9 (52)	1.75 (57)
20	0.8 (125)	5.6 (54)	4.76 (63)
30	3.23 (124)	1.8 (58)	3.64 (55)
	619 cases S.C.R. 97.08%	263 cases S.C.R. 96.7%	
Duplicate Material E.3143			
5	5.3 (75)		
10	2.6 (76)

Statistical Analysis of Results E.3061 and E.3143 Combined

 χ^2 2.142 .. df 4 .. P 0.7

The results are homogeneous, and no statistical difference exists between the several samples.

* This series, tested 15 months after a single inoculation, is obtained by retesting all the children available who were injected with batch E.3061 and found negative three months later. (Although the antigen in Schick toxin results in a definite second response effect, this is transitory and does not affect the immunity level when the tests are repeated 12 months later. This was shown by the study of a further 239 children, who received the same material and were not post-Schick tested until 12 months after the single inoculation. This group showed an overall conversion rate of 95.4%, which compares with an approximate 93.3% for the group (271 cases) which received the intermediate Schick test.) The findings thus represent the persistence rate of immunity in children who responded to a single inoculation. To get a true picture of the situation in such a group of children as is shown in the results of the three-months test in batch E.3061 at a period of 15 months (assuming that those who failed had not received a further inoculation), it is necessary to add the percentage of failures in the original group to the failures found 15 months after inoculation. If this is done one can say that the expectation in the five groups not post-Schick-tested for 15 months would be approximately:

5 Lf still Schick + at 15 months	..	9.1%
10 Lf " " " " " "	..	5.7%
15 Lf " " " " " "	..	5.8%
20 Lf " " " " " "	..	5.8%
30 Lf " " " " " "	..	6.9%

With the possible exception of the 5 Lf series, these figures would compare reasonably favourably with those obtained 15 months after the present routine two-injection treatment with A.P.T.

pH of P.T.A.P.

It was noted by Dr. W. B. Stott (M.O.H., Cuckfield) and one of us (G.B.) that during the injection of P.T.A.P. babies showed some signs of temporary discomfort. It was obviously desirable to rectify this if it could be done without affecting the efficiency of the prophylactic.

That the injection of P.T.A.P. in 0.5-ml. doses did cause some pain was confirmed by inoculating a number of adults. The pain, which was trifling and transient, was suspected to be due to the slight acidity of the prophylactic—pH 5–5.2. When the reaction was altered to pH 7, or even to pH 6, and again tested on adults, it was found that, apart from the needle puncture, the injection was painless. It became necessary, therefore, to determine the stability and efficiency of P.T.A.P. prepared in such a way that the final mixture was so nearly neutral that pain was avoided.

A quantity of P.T.A.P. was prepared containing 30 Lf of purified toxoid and 10 mg. AlPO_4 per ml.; one part was adjusted to pH 5 as usual and the other to pH 6.5. Both samples were then left at room temperature (20–22° C.) for six months and tested for potency by animal assay as follows: They were each diluted 1 in 60 with physiological saline, and 1-ml. quantities were injected subcutaneously into normal guinea-pigs.

The dose, therefore, was 0.5 Lf and 0.16 mg. of mineral carrier. The animals were bled four weeks later and the

sera from each group pooled. At the same time they were given a second identical inoculation. Two weeks later they were bled again, and the antitoxin titre of each serum was determined. The results obtained are shown in Table V.

TABLE V.—Animal Assay of Acid and Nearly Neutral P.T.A.P., Lf 30, 10 mg. AlPO_4 /ml. (Six Months Matured at Room Temperature)

Pig No.	Group A (P.T.A.P., pH 5)		Group B (P.T.A.P., pH 6.5)	
	Mean Value 28 days after 1 dose 0.2 u./ml.		Mean Value 28 days after 1 dose 1.0 u./ml.	
	Individual Values 14 days after 2nd dose, u./ml. serum		Individual Values 14 days after 2nd dose, u./ml. serum	
1	2.5		10	
2	0.2		8	
3	7.0		7	
4	1.5		1.5	
5	1.0		3	
6	4.0		1.5	
7	2.2		4	
8	0.1		2	
9	5		8	
10	2		3	
11	1.25		2.5	
12	2		—	
Arithmetic Mean	..	2.4	..	4.6
Geometric Mean	..	1.48	..	3.4

Statistical Analysis

$$= \sqrt{\frac{\bar{x}}{s^2 (n_1 + n_2)}} = 2.1$$

which, for 21 degrees of freedom, gives a P value of 0.05.

From the figures obtained it seemed probable that the prophylactic at a reaction of pH 6.5 was actually a better antigen than that at pH 5.

For the purpose of determining by clinical trial the relative efficiency of nearly neutral and acid P.T.A.P. three preparations were made: (a) P.T.A.P., Lf 30, 10 mg. AlPO_4 /ml., pH 6.5; (b) P.T.A.P., Lf 30, 15 mg. AlPO_4 /ml. pH 6.5; and (c) P.T.A.P., Lf 30, 10 mg. AlPO_4 /ml., pH 5. They were matured for six months at room temperature before use.

As before, Schick-positive children between their first and second birthdays were used. The dose administered was 0.5 ml. intramuscularly, and the Schick conversion rate was observed four weeks later. The "pain factor" was assessed on three grounds—"reaction" to (1) the needle-pain, (2) the actual pressing of the syringe plunger (the inoculation proper), and (3) duration of "reaction" after withdrawal of the needle.

These factors were assessed as carefully as possible and were recorded as +, ++, or ++++. The total number of plus signs set down against each preparation was divided by the number of cases observed.

TABLE VI.—Comparison of P.T.A.P. at pH 5 and pH 6.5 (S.C.R. Observed Four Weeks After a Single Intramuscular Inoculation of 0.5 ml.)

Composition of P.T.A.P.			Post-Schick Results			
Lf/ml.	pH	AlPO_4 /ml.	(+)	(-)	S.C.R.	"Pain-factor"
A. 30	6.5	10 mg.	2	206	99.0	0.68
B. 30	6.5	15 mg.	10	181	94.8	0.65
C. 30	5.0	10 mg.	4	167	97.7	1.05

Statistical Analysis

I. Series A and B (comparison of the 10- and 15-mg. preparations at pH 6.5):

$$\chi^2 = 4.612; \text{df} = 1; P = < 0.05$$

(after Yates's correction for continuity, difference significant at the 5% level).

II. Series A and C (comparison of the pH 5 and pH 6.5 preparations):

$$\chi^2 = 1.47; \text{df} = 1; P = 0.25$$

The results, summarized in Table VI, show that there was a greatly reduced overall "reaction" to the pH 6.5

nixtures. Furthermore, they reveal that there was no eduction in potency when such mixtures were used—in fact, the results obtained with the 10 mg./ml. preparation were virtually perfect, and indicated that 10 mg./ml. of aluminium phosphate is optimal.

Résumé, and Conclusion Arising from Latest Findings

It is now four years since field trials on P.T.A.P. were begun. A number of important points had to be unequivocally established. It has been shown that in order to obtain the best results a far greater amount of carrier must be used than would be considered safe if presented as A.P.T. With these very large amounts of carrier the remarkable conversion rates of 97–99% following a single inoculation have been achieved, and this immunity has been shown to persist in 94% of the children for 15 months or more. Of equal importance is the virtual absence of local or general reactions; and not one child in over 6,000 inoculated developed a sterile abscess.

The work progressed in stages. Up to now the optimal amount of mineral carrier has been determined, the route of choice has been found, an approximation of the requisite quantity of purified toxoid has been made, and most of the discomfort of the earlier preparations has been abolished. Also, as a result of improved laboratory technique, the purity of the toxoid employed as routine procedure has been increased to 2,000 Lf/mg. p. N₂ (90% pure toxoid). Toxoid of this purity was used in all the more recent work described above.

On the basis of these findings the composition of P.T.A.P. now prepared is as follows:

AIPO ₃	10 mg./ml.
Toxoid:		
(a) amount	50 Lf per ml. (by law)
(b) purity	2,000 Lf/mg. p. N ₂
NaCl	0.85%
Preservative	0.01% sodium ethyl mercury thiosalicylate
Reaction	pH 6–6.5

The prophylactic is stored at room temperature for three to six months before issue.

Summary

Purified toxoid, aluminium phosphate precipitated (P.T.A.P.), is an accurately standardized diphtheria prophylactic, which in its antigenicity, stability, and freedom from reactions has distinct advantages over alum-precipitated toxoid (A.P.T.).

Study of the results obtained from experimental work and field trials shows that: (a) The optimal amount of mineral carrier for young children is 5 mg. AIPO₃, in a 0.5-ml. dose. (b) Intramuscular inoculations confer appreciably better immunity than do subcutaneous. (c) P.T.A.P. produces a definitely better Schick conversion rate than does A.P.T. A single inoculation of 0.5 ml. P.T.A.P. containing 10 or more Lf units of purified toxoid and 10 mg. AIPO₃ per ml. produces in children a Schick conversion rate of >95% one month after injection. At three and six months the S.C.R. is still over 95%, and has not fallen appreciably even after fifteen months. (d) P.T.A.P., adjusted to pH 6, is an antigen at least as efficient as the earlier more acid (pH 5) preparation, and causes less discomfort on inoculation.

The composition of P.T.A.P., as now prepared, is accurately described.

For facilities at various stages of this work we desire to thank Dr. A. Anderson, M.O.H., Heston and Isleworth; Dr. H. W. Barnes, M.O.H., Camberwell; Dr. P. L. T. Bennett, M.O.H., Fulham; Dr. H. D. Chalke, D.M.O., No. 7 London Division; Dr. H. Smith, D.M.O., No. 1 London Division; Dr. A. G. G. Thompson, M.O.H., Lambeth; and Dr. W. H. S. Wallace, D.M.O., No. 8 London Division. Grateful thanks are also due to Dr. L. Cavalli, of the Department of Genetics, Cambridge, for assistance in the statistical analyses.

A METHOD OF INCREASING THE LUNG BLOOD SUPPLY IN CYANOTIC CONGENITAL HEART DISEASE

BY

N. R. BARRETT, M.Chir., F.R.C.S.

AND

RAYMOND DALEY, M.D., M.R.C.P.

(From the Departments of Thoracic Surgery and Cardiology,
St. Thomas's Hospital, London)

The purpose of this report is to describe an ancillary method of increasing the pulmonary blood supply in patients suffering from congenital cyanotic heart disease in whom the main defect is inadequate blood flow to the lungs. There are already two methods of increasing this blood supply. An anastomosis has been created between a systemic artery and one of the pulmonary arteries (Blalock, 1947; Potts and Gibson, 1948), and valvulotomy has been successfully practised in patients with valvular stenosis (Brock, 1948; Sellors, 1948).

These procedures have improved many seriously incapacitated children. Enthusiasm has been rekindled in a field in which endeavour had almost ceased, and physicians and surgeons have been brought together at a time when "progress" has often led to divergence of paths.

Theoretical Considerations

It has been found that anastomosis or valvulotomy may not be practicable or advisable in every case. There are patients in whom the pulmonary arteries may be absent or too small for any form of anastomosis. The Blalock type of operation may be impossible if the aortic arch lies at the base of the neck or if there is unusual aortic branching.

The clinical condition of some patients is so serious before operation that even the most skilled and experienced surgeon may hesitate to embark upon a procedure which may take many hours to complete. Conversely, some congenital cardiac deformities alter function to such a minor degree that it is unreasonable to undertake an operation of great magnitude. Therefore, if a simple operation could be devised which offered hope of amelioration it might serve a purpose in some cases.

It occurred to one of us (N.R.B.) that a simple alternative method of improving these patients might be to produce vascular pleural adhesions and so to bring blood into the lungs from the parietes. Attempts to revascularize the heart (by omentopexy and similar procedures) have been disappointing, but there are reasons for believing that success might be achieved if the same principles were applied to the lungs. These reasons are:

(a) Some children are born without pulmonary arteries and survive; thus blood from systemic collateral vessels can reach the alveoli.

(b) In patients suffering from pulmonary tuberculosis in whom an artificial pneumothorax has been induced and

adhesions cauterized it is common to find blood vessels either in the middle of adhesions or, as isolated strands, spanning the pneumothorax from the parietes to the visceral pleura. These vessels carry blood from the extrapleural tissues to the lung and sometimes are the main blood supply to a diseased area: for instance, if vascular adhesions over a large tuberculous cavity situated near the edge of the lung are divided the peripheral wall of the cavity may slough.

(c) At thoracotomy performed on patients suffering from Fallot's tetralogy collateral vessels coming from the mediastinal, the phrenic, and the internal mammary arteries are often seen entering the hilum of the lung. It is well known that in some of these patients death may follow a thoracotomy when an anastomosis could not be achieved, and this may be due to severance of collateral vessels in the course of dissection.

With these points in mind, thoracotomies were performed upon two patients suffering from Fallot's tetralogy, and the experiences obtained gave clinical support to the proposition. The object was to perform a Blalock's operation, but in neither case could the operation be carried out.

The first patient was a small girl. The right chest was opened in the hope that the right subclavian could be anastomosed to the right pulmonary artery. Dense, diffuse vascular adhesions were found, and it was only after these had been divided that the hilum was reached and a very small pulmonary artery isolated. This artery was not clamped, but about twenty minutes later the child died, and at necropsy it was found that the left pleural cavity was obliterated by adhesions and that the left pulmonary artery was also diminutive. Death probably occurred because an important collateral circulation had been removed on the right side as the pleural adhesions were cut to expose the hilum.

The second patient was also a little girl. The aortic arch was high in the mediastinum, and the innominate artery came off so far towards the left side that it was anatomically impossible to approximate the right subclavian to the pulmonary artery. A good deal of dissection in the mediastinum was carried out before the attempt was abandoned, and in the end the mediastinal pleura was not closed because of oozing from the raw surface which was left. After the operation the parents were informed that nothing beneficial had been achieved or could be done; hence it was surprising to find a few months later that the girl was much improved. Before this operation she could walk only 40 to 50 yards (37-46 metres) before becoming severely dyspnoeic, whereas after operation she could walk a mile (1.6 km.). Since then a further operation has been performed on the left side and adhesions have been deliberately created. She can now walk three miles (4.8 km.), has given up her push-chair, and goes to an ordinary school. (See Case 1, below.)

Surgical Technique

After these experiences operations were developed expressly to create vascular adhesions, and they have been practised when, for the reasons already described, systemic pulmonary anastomosis or valvulotomy seemed to be impracticable. The ordinary methods of pleurodesis, such as the injection of a small amount of strong silver nitrate into the pleural cavity or insufflation of iodized talc, were not used, because it was felt that more effective blood vessels would be created if the surface of the lung was brought into direct contact with the vessels in the chest wall. For this reason the first cases were treated by opening both pleural cavities—at separate operations—and removing the parietal pleura from the upper mediastinum, from the dome of the pleura, and from the upper half of the chest. Powdered asbestos (0.4 g.) was

dusted on to the raw surfaces, the chest was closed and, after instituting temporary drainage, the lung was completely re-expanded.

At each of these operations a fairly extensive examination of the anatomy of the congenital abnormality was undertaken and the pericardium was often opened, but in spite of this the children sustained the procedures well and there has been no mortality. The parietal pleura has not been stripped off the lower part of the chest and the diaphragm, because it was felt that this might reduce the vital capacity too much. We have found that bilateral excision of the pleura actually reduces the vital capacity by about 200 ml. in children under the age of 10 years.

Another type of operation to improve the circulation to the lungs has also been tried. The great omentum has been brought up into the chest and placed in contact with the left lung. The use of the omentum, although attractive in that it carries a large blood supply and can easily be transposed to the lung, is not without theoretical and practical disadvantages. Experience gained in the management of recent chest wounds has shown that whenever a knuckle of omentum passes through a small hole in the diaphragm a diaphragmatic hernia begins to form and steadily increases in size as more and more omentum is insinuated into the pleural cavity. Hence any method of bringing the omentum straight up through a convenient artificial hole in the diaphragm is certain to be complicated by the development of a diaphragmatic hernia. To overcome this the omentum has first been brought up into the upper part of the rectus sheath so that it lies immediately superficial to the muscle fibres of the transversus abdominis and deep to the rectus abdominis. From this point it has been introduced into the left pleural cavity by creating a tunnel in the tissue behind the costal margin and then spread out and stitched in the fissure between the upper and lower lobes of the left lung. As large a surface of the lung as possible has been brought into contact with the omental vessels. Powdered asbestos has been dusted on to the fissural surfaces of the lung before the omentum has been stitched into place.

Results

This communication is a preliminary report and is submitted because the surgery of congenital cyanotic heart disease is progressing so rapidly that ideas and experiences gained from a small group of patients may be useful stepping-stones to better surgical treatment.

Assessing results of operation is a matter of difficulty. The majority of "blue children" lead sheltered lives and their activity is restricted to a degree which is not commensurate with their ability. Hence a stay of a few weeks in hospital, where the services of physiotherapists and occupational therapists are available, almost invariably improves the morale of the patient and increases functional ability. The sensitive, uncommunicative child lying in bed with clubbed fingers hidden under the bedclothes soon becomes active, and tries to play games and to sit at table with the others for meals. These factors must be taken into consideration before increased exercise tolerance can be attributed to the beneficial result of any particular operation, but increased exercise tolerance is an important method of assessing any treatment and it is of course the criterion by which the patient and relatives judge improvement.

Estimations of arterial oxygen saturation provide evidence of improvement if the conditions under which the blood is taken remain comparable and the child is not upset by the procedure. Decrease of polycythaemia and oxygen capacity is good evidence of improvement if enough time is allowed for correction of post-operative anaemia.

Probably the most satisfactory objective evidence is obtained by the measurement of oxygen intake as a percentage of ventilation before and after a standard exercise according to the method of Courmand (Baldwin, Courmand, and Richards, 1948) and Bing (Bing *et al.*, 1947). From the results of this test the pulmonary blood-flow response to effort can be inferred.

In the following case histories it will be seen that only some of these tests have been carried out in the majority of the patients.

Case Histories

Case 1.—A girl aged 8 years suffered from the tetralogy of Fallot. She was very cyanosed and unable to walk up more than one flight of 12 stairs. She squatted frequently and the edges of her frock were soiled and torn. The oxygen capacity was 25.9 vols.%. The aortic arch was so high in the mediastinum that no systemic artery could be brought down to the pulmonary artery. At the first operation, in April, 1948, the right hemithorax and superior mediastinum were explored. No collateral vessels were found. Three months later she was able to walk one mile on the flat. In August, 1948, the upper half of the parietal pleura on the left side was removed and 0.4 g. of asbestos insufflated. By December, 1948, she could walk two to three miles (3.2 to 4.8 km.) on the flat, was able to climb 50 stairs without dyspnoea, and had ceased to squat. Her arterial oxygen saturation was then 80% at rest and 45% after walking up and down three flights of stairs. Oxygen capacity was 23.3 vols.%.

Case 2.—This patient, a girl aged 16 years, had been to an ordinary school but had to be taken there in an invalid chair. She subsequently worked as a bookbinder. She was able to lead only a sedentary life and could not walk up more than one flight of stairs or dance slowly more than once round a ballroom. She suffered from the tetralogy of Fallot, and before the first operation the resting arterial oxygen saturation was 78%. Oxygen capacity was 28.2 vols.%. It was felt that her disability was not of sufficient degree to warrant a major operation. Consequently in May, 1948, a right thoracotomy was performed. A few apical vascular adhesions were present, which were divided when the upper parietal and mediastinal pleurae were removed, and 0.4 g. of asbestos was insufflated over the exposed area. In October, 1948, the same procedure was carried out on the left side. By January, 1949, she was able to walk about 1½ miles (2.4 km.) on the flat and go up three or four flights of stairs, and had attended a dance "without anyone knowing there was anything wrong with me." Her arterial oxygen saturation was then 88% at rest and 60% after walking up three flights of stairs. Oxygen capacity was 23.4 vols.%.

Case 3.—A mentally retarded boy aged 13 years was suffering from pulmonary stenosis and an interventricular septal defect. He was very dyspnoeic after walking 50 yards (46 metres) and when in hospital squatted most of the time. The arterial oxygen saturation was 85% at rest. Oxygen capacity was 20.8 vols.%. Oxygen consumed per litre ventilated was at rest 33.5 ml., after standard exercise 26.7 ml. Carbon dioxide produced per litre ventilated was at rest 26.5 ml., after standard exercise 21 ml. In September, 1948, a right thoracotomy was performed. There were no adhesions and no visible collateral vessels. The upper halves of the parietal and mediastinal pleurae were removed and 0.4 g. of asbestos was insufflated. In November a similar operation was carried out on the left side and in addition an omental graft was brought up to the left lung. By January, 1949, he was able to run up and down six flights of stairs without undue dyspnoea and had entirely given up squatting. Arterial oxygen saturation was then 84.5% at rest and 62.1% after exercise. The oxygen capacity was 21.4 vols.%. Oxygen consumed per litre ventilated was at rest 30 ml., after standard exercise 36 ml. Carbon dioxide produced per litre ventilated was at rest 21.7 ml., after standard exercise 23 ml.

Case 4.—A well-developed girl of 12 years who had been blue from birth was proved by angiocardiology to have a common truncus arteriosus and absent pulmonary arteries. She attended an ordinary school and was able to walk about

440 yards (400 metres) slowly on the flat, but was very dyspnoeic after ascending three flights of stairs. The arterial oxygen saturation was 57.5% at rest and 44% after three flights of stairs. Oxygen capacity was 33.3 vols.%. Oxygen consumed per litre ventilated was at rest 18 ml., after standard exercise 14.5 ml. Carbon dioxide produced per litre ventilated was at rest 17.5 ml., after standard exercise 12.5 ml. In November, 1948, a left thoracotomy was performed and the absence of a pulmonary artery on the left side was confirmed. There were a large number of collateral vessels entering the hilum. Pleural adhesions were absent. The omentum was grafted into the interlobar fissure, and the upper half of the parietal pleura was removed, 0.6 g. of asbestos being insufflated over the raw surface. Three months later (*i.e.*, after only one side of the chest had been operated upon) her exercise tolerance had increased by about 50%. The arterial oxygen saturation was then 73% at rest and 46% after three flights of stairs. Oxygen capacity was 25.9 vols.%. Oxygen consumed per litre ventilated was at rest 24.5 ml., after standard exercise 23 ml. Carbon dioxide produced per litre ventilated was at rest 22.7 ml., after standard exercise 18.8 ml.

Case 5.—A timid girl aged 10 years was suffering from Fallot's tetralogy and arachnoidactyly. Her deformities were so great that she had been almost constantly bedridden. She became dyspnoeic after struggling along a few steps. Arterial oxygen saturation was 42% at rest. Oxygen capacity was 30.1 vols.%. In May, 1948, the right hemithorax was explored. The innominate artery bifurcated at the base of the neck, and an anastomosis using the right subclavian artery would have been very difficult. No adhesions were present, but there was some collateral circulation. A large area of parietal and mediastinal pleura was removed and 0.4 g. of asbestos insufflated. In August, 1948, a similar operation was performed on the left side. After many months in hospital she was educated to walk, and by January, 1949, she was able to walk about 50 yards unaided. Arterial oxygen saturation was 55% at rest. Oxygen capacity was 25.8 vols.%.

Case 6.—A mentally retarded boy aged 12 years was suffering from Fallot's tetralogy. He had attended an ordinary school, but since 1945 his activities had been so limited by dyspnoea that his attendances became very infrequent. He squatted a great deal and his maximum slow-walking distance was about 100 yards (92 metres). Oxygen capacity was 29.1 vols.%. In July, 1948, a right thoracotomy was performed. There were few collateral vessels and no pleural adhesions. The right subclavian artery was unsuitable for anastomosis because it came from the aortic arch distal to the left subclavian. The pulmonary arteries were very small. Accordingly the right parietal and mediastinal pleurae were extensively removed and 0.4 g. of asbestos was insufflated. A similar operation on the left side was carried out in September, 1948. When seen in February, 1949, he had ceased to squat and his range of activity had increased so that he could walk up 72 stairs or about 440 yards on the flat without discomfort. Oxygen capacity was 22.1 vols.%. His mother reported that she recently went to collect him at school in his wheel-chair, but he had run several hundred yards and arrived home before her.

Conclusion

Judged by clinical means, such as improved exercise tolerance, diminution of cyanosis, and less frequent squatting, it is considered that there have been two good results (Cases 1 and 3) and that three patients have shown considerable improvement (Cases 2, 4, and 6). One patient (Case 5), whose condition was complicated by arachnoidactyly, has been educated to walk, but her skeletal deformity is so great that improvement is difficult to assess.

Of the four cases of which there are details of resting arterial oxygen saturation before and after operation significant improvement has occurred in three (Cases 2, 4, and 5) and no change in one (Case 3).

In six patients the blood oxygen capacity was measured before and after operation and was significantly decreased in four. One patient (Case 3), although clinically improved, showed no change in arterial oxygen saturation or oxygen

capacity, but his oxygen intake and carbon dioxide production, measured as a percentage of ventilation, changed from markedly abnormal to normal figures.

The results may be improved after a longer follow-up period than three to four months, but it is thought that as preliminary observations they are encouraging enough to warrant further application of the procedure to patients who for various reasons are unsuitable for the types of surgery already devised.

Our thanks are due to Miss M. Young, of the Sherrington School of Physiology, and to Dr. Evan Jones and Dr. M. B. Matthews, of the cardiac department, St. Thomas's Hospital. We would also like to state that Dr. James W. Brown has seen these patients and encouraged us to further trials.

THE ASSOCIATION OF MATERNAL OBESITY, LARGE BABIES, AND DIABETES

BY

J. A. L. GILBERT, M.D., F.R.C.P.Ed., M.R.C.P.
Lund Research Fellow of the Diabetic Association

(From the Clinical Endocrinology Research Unit of the Medical Research Council, University of Edinburgh)

The obstetric histories of the majority of diabetic women are characterized by an abnormally high foetal loss rate before the onset of clinical diabetes (Miller, Hurwitz, and Kuder, 1944; Miller, 1945; Henley, 1947; Gilbert and Dunlop, 1949). The foetal loss rate shows a progressive increase during this period, reaching a maximum in the immediately pre-diabetic phase, and is higher among women developing diabetes before the age of 45 than among those in whom the disease has its onset after this age.

Allen (1939), in reviewing the obstetric histories of diabetic women, noted that a high percentage of large babies were born many years before the onset of clinical diabetes. Further, Miller, Hurwitz, and Kuder (1944) report the incidence of babies with birth weights in excess of 11 lb. (5 kg.) to be as follows; non-diabetic women, 0.07%; pre-diabetic women, 3.9%; and diabetic women, 6.4%. Miller (1945, 1946) surveyed the birth weights of 22 babies born to 16 mothers who eventually developed diabetes after the age of 40. All deliveries were carried out in the hospital at which these women later sought treatment for their diabetes. Of the 22 babies three weighed 5 kg. (11 lb.) or more, six weighed 4.5 kg. (9.9 lb.) or more, and 15 weighed 4 kg. (8.8 lb.) or more. The number of babies in each weight group was 200, 27, and 7 times the expected incidence respectively, which led him to conclude that women developing diabetes after the child-bearing age are recruited almost wholly from the 5-7% of mothers giving birth to babies weighing more than 4 kg. (8.8 lb.). The recent publication of Kriss and Fitcher (1948) confirms these observations. These workers report that 58% of their diabetic women had at some time prior to the onset of clinical diabetes given birth to at least one baby of 10 lb. (4.53 kg.) or more in weight. The average "latent period" between the birth of the first of such babies and the development of diabetes was 24.2 years.

Large babies were formerly attributed to maternal hyperglycaemia, resulting in the transfer of an excess of glucose to the foetus. Bill and Posey (1944), Bigby and Jones (1945), and Henley (1947), however, report the delivery of large babies in spite of well-controlled diabetes, and this has also been my experience.

White and Hunt (1943) and White (1946) conclude from observations of diabetic pregnancies that the unusually large babies are accounted for by an excess of chorionic gonadotropin.

Allen (1939) observed a relationship between excessive maternal gain in weight during pregnancy and the birth of large babies. Watts (1935) and others, who injected into pregnant rats what was at that time assumed to be anterior pituitary growth hormone, observed an unusual gain in maternal weight and in foetal size; such finding may in some measure explain Allen's observations. The report of Miller (1946) again suggests the importance of the growth hormone in the production of large babies: he drew attention to the similarity of the splanchnomegaly observed in the babies of diabetic mothers to that found in acromegalic patients.

Young has often stressed the relationship between the growth-promoting and the diabetogenic effects of anterior pituitary extracts. Thus in 1941 he reported that puppies treated for long periods with daily injections of diabetogenic pituitary extract failed to exhibit glycosuria as did adult dogs, but rapidly increased in weight. Diabetes did eventually develop, however, in some of the animals after many months' treatment. Further injections of the anterior pituitary extract produced only a diabetogenic effect, the growth-promoting influence having been lost. Luken (1946) suggests that diabetes does not result from an excess of any one anterior pituitary hormone but from the combined oversecretion of both the growth and the adrenotropic hormones.

It is thus apparent that maternal obesity, an abnormally high foetal loss rate, and an unusually high incidence of large babies may occur many years before the onset of clinical diabetes, and that the investigation of women with such obstetric histories may show that a considerable proportion of them become diabetic in the course of time. Such a group of women form the basis of the present investigation.

Selection of Patients

Pre-diabetic foetal loss reaches a maximum during the two-year period immediately before the diagnosis of diabetes (Gilbert and Dunlop, 1949). It follows that some of the women who in 1941-3 had abnormal obstetric histories but showed no signs of diabetes might in 1948 have developed this disease.

The obstetric histories of 5,000 women confined in the Simpson Memorial Maternity Pavilion, Edinburgh, between August, 1941, and April, 1943, were therefore examined and 150 of these were found to have unexplained histories of repeated abortions, miscarriages, intrauterine deaths, neonatal deaths, and babies weighing 10 lb. or more. Mimeographed forms asking for the results of all pregnancies since 1941-3 were sent to these women, but owing to the evanescent nature of Edinburgh's wartime population only 75 replies were received. Thirty-five of these gave histories of one or more normal pregnancies since 1941-3 and were therefore discarded from the investigation. The remaining 40 had either not been pregnant since 1941-3 or had had abnormal pregnancies. Of these it has been possible to examine 21 in hospital, the remaining 19 having declined admission owing to pressing domestic obligations.

The usual glucose-tolerance test was performed on all 1 patients, six of whom showed curves which were typically diabetic—i.e., they had fasting blood-sugar levels of more than 120 mg. per 100 ml. and levels which rose to more than 200 mg., remaining above 120 mg. at the end of two hours.

Table Comparing Patients with Diabetic Blood-sugar Curves and those with Normal Curves

	Diabetic G.T.T.	Non-diabetic G.T.T.
No. of patients	6	15
Age	39-46 years; aver. 44.2 years	28-45 years; aver. 39.3 years
Obese	6	8
No. of live births	25	40
No. of babies more than 10 lb.	11	5
No. of patients with babies of 10 lb. or more	5	3

G. T. T. = Glucose-tolerance test.

From the accompanying table it will be seen that the average age of those patients with diabetic blood-sugar curves was five years above that of those with normal curves. It seems probable, therefore, that some women of the latter group may yet develop a diabetic tendency.

The very high incidence of obesity is remarkable, 14 of the 21 patients being more than 14 lb. (6.35 kg.) in excess of the normal mean weight for their age and height, while all six patients with diabetic blood-sugar curves were 10 lb. (13.6 kg.) or more above their "correct" weight. All patients dated the onset of obesity from their first or second pregnancy, and with each successive pregnancy there had occurred a further gain in weight. Obesity was a less pronounced feature among the women with normal blood-sugar curves than among those who had become diabetic.

Women with unsatisfactory first pregnancies are usually admitted to the Simpson Memorial Maternity Pavilion for second and subsequent confinements. Consequently, accurate birth weights of the majority of viable infants in this group were available. The difference in the incidence of babies weighing 10 lb. or more among the diabetic and non-diabetic groups of women is striking—11 out of 25 compared with 5 out of 40. Thus there seems to be an association between the production of large babies and ensuing maternal diabetes.

Obese Non-diabetic Women

The high incidence of obesity among women with unsatisfactory obstetric histories suggests that maternal obesity may be related to a high foetal loss rate. The second step in the present investigation therefore consisted in a survey of the obstetric histories of 84 obese non-diabetic women attending the dietetic out-patient department of the Royal Infirmary, Edinburgh. All patients were interviewed personally. The group was unselected, and represented 84 consecutive attendances of obese non-diabetic women at the department.

As in the previous group of patients, the vast majority of these women associated the onset of obesity with an early pregnancy. The ages of these patients varied between 35 and 72 years, with an average of 46.8. Among the 341 pregnancies involved there was a foetal loss rate of 13.4%. This rate is similar to the pre-diabetic foetal loss rate of 12.5% observed by Gilbert and Dunlop in women developing diabetes after the age of 45, the majority of whom were over weight, and contrasts with the control foetal loss rate of 8%.

The majority of confinements among the obese non-diabetic women and among the women developing diabetes after the age of 45 were carried out either at home or in

institutions from which birth-weight records were not available. Consequently it was impossible to ascertain the precise incidence of large babies. However, many patients spontaneously volunteered the information that they had had large babies, quoting birth weights of up to 14 lb.

Discussion

The present investigation reveals that six out of 21 women who had had obstetric histories of a high foetal loss rate and who had given birth to babies weighing 10 lb. or more eventually developed diabetes and that the diabetes was associated with obesity. Thus the incidence of diabetes in those women far exceeds the expected incidence of diabetes in a similar age group of women which is given by Joslin (1946) as 0.864%. The association between the production of large babies and the development of maternal diabetes which was noted by Miller (1945) and Kriss and Fletcher (1948) is therefore confirmed by the present study.

The abnormally high foetal loss rate in the obese non-diabetic women of the present survey is similar to that occurring in the obstetric histories of women developing diabetes after the age of 45, most of whom were also obese (Gilbert and Dunlop, 1949). The unusually high incidence of the birth of large babies was a further similarity in the obstetric histories of these two groups of patients. The present observations therefore suggest that close correlation exists between increasing maternal obesity, the production of large babies, and ensuing maternal diabetes.

Both clinical and experimental studies suggest that the anterior pituitary lobe plays an important part in the production of obesity, large babies, and diabetes. The frequent onset of obesity and diabetes at the time of the menopause has been attributed to anterior pituitary overactivity secondary to the loss of the inhibiting effect of oestrogens on the pituitary. Further, the onset of obesity and a diminished carbohydrate tolerance following spontaneously occurring or artificially produced amenorrhoea, as was reported by Ogilvie (1935), supports this hypothesis. The reported results, however, of oestrogen therapy in menopausal diabetes are conflicting.

Young (1941, 1945), from his experimental observations, concludes that excess diabetogenic activity of the anterior pituitary lobe may be balanced by hyperfunction of the pancreatic islets induced through an overproduction of the anterior pituitary pancreatic hormone. The effect of such a balance is the production of growth by a reduction in carbohydrate oxidation and an associated conservation of nitrogen (Young, 1941, 1945; Ogilvie, 1944). The resulting growth manifests itself, according to the age of the patient, either in the abnormal height of the pre-diabetic juvenile or in the obesity of the middle-aged subject. This growth is maintained only so long as the pancreatic islets respond to the excessive secretion of pancreatic hormone, but ultimately islet exhaustion may supervene, manifesting itself in cessation of growth and clinical diabetes. Other observations are in accord with this hypothesis. Thus, Ogilvie (1933, 1935) has reported pancreatic islet hypertrophy in a high proportion of obese non-diabetic subjects and a latent period of many years between the onset of obesity and the occurrence of diabetes. Further, Joslin (1946) notes that a rapid loss of weight by obese subjects may precede the onset of diabetes.

Applied to the present study these findings suggest that the anterior pituitary growth factor may be in part responsible for the maternal obesity and diabetes, and that this factor passes across the placenta, causing the foetus to be both abnormally long and abnormally fat. The foetus

thus appears to combine the type of growth displayed by both the pre-diabetic juvenile and the obese middle-aged diabetic.

The clinical and experimental observations discussed suggest that an excessive secretion of the anterior pituitary growth factor during pregnancy may account for the production of progressive maternal obesity, large babies, and ultimate maternal diabetes.

Summary

Twenty-one women with obstetric histories of unexplained abortions, miscarriages, intrauterine deaths, stillbirths, and neonatal deaths, and the birth of babies weighing 10 lb. or more, were admitted to hospital for investigation. Six of these patients were found to be diabetic. All six were grossly obese and five had had babies weighing 10 lb. or more.

Evidence is brought forward to show a correlation between progressive maternal obesity, the birth of unusually large babies, and ensuing maternal diabetes. It is suggested that an excessive secretion of the growth factor during pregnancy may account for the associated phenomena.

I wish to thank Professor D. M. Dunlop and Dr. R. F. Ogilvie for their helpful advice and criticism, and Professor R. J. Kellar for so kindly putting the case records of the Simpson Memorial Maternity Pavilion at my disposal.

GLOSSITIS IN ADDISONIAN PERNICIOUS ANAEMIA

EFFECT OF SYNTHETIC VITAMINS OF THE B COMPLEX

BY

ALEXANDER BROWN, M.D., F.R.F.P.S.
M.R.C.P.Ed.

(From the Muirhead Department of Medicine, the University and Royal Infirmary, Glasgow)

Glossitis has been recognized as a common feature of Addisonian pernicious anaemia since the work of Hunter (1909). Some evidence of involvement of the tongue is obtained in about 70% of cases (Brown, 1946). Adequate treatment of the anaemia with potent liver extract usually results in the disappearance of oral symptoms.

Glossitis is also a common feature of the sprue syndrome and of many deficiency states such as pellagra. Its occurrence has been attributed to deficiency of specific vitamins such as nicotinic acid and riboflavin. The fact that the sore tongue of the pernicious anaemia syndrome is indistinguishable from that occurring in well-recognized nutritional deficiencies suggests that in pernicious anaemia it may again be due to a vitamin deficiency, and that it may

be corrected by appropriate treatment with one or more of the members of the vitamin B complex.

The present report describes the occurrence of glossitis and a syndrome suggestive of ariboflavinosis in patients with Addisonian pernicious anaemia and the effect of treatment with certain synthetic vitamins of the B complex.

Clinical Observations

Seven patients with pernicious anaemia are described in whom there was a well-marked disturbance suggestive of deficiency of one or more members of the vitamin B complex. The diagnosis of pernicious anaemia was made on the following grounds. In all cases the clinical picture was compatible with the diagnosis; all had a macrocytic anaemia with a megaloblastic bone-marrow reaction which showed a satisfactory response after treatment with highly purified liver extract; all had a histamine-fast achlorhydria, and in none was there evidence of steatorrhoea or dietary defect.

Of the seven patients, six had severe painful glossitis. Five of the six had been receiving parenteral liver therapy for periods ranging from four months to two years; they were receiving it regularly every two to four weeks during the period of this present study. As indicated in the case reports, the glossitis had either existed since the original illness or developed during its treatment with parenteral liver. The development of a sore tongue was not always controlled by liver therapy, and on occasion bore no relation to the immediate or subsequent haematological status of the patient. In the seventh case (treated for five years) glossitis was associated with angular stomatitis and vascularization of the cornea.

Case 1

A man aged 58 developed pernicious anaemia, for which liver therapy was started in February, 1946. His tongue was red, glazed, and smooth, but did not cause pain until June 1946, when its appearance deteriorated and it became extremely sensitive and painful. Blood levels at this time and during the subsequent six months were maintained above 4,500,000 red cells per c.mm. by regular administration of anahaemic. From June 15, 200 mg. of nicotinic acid daily for seven days left the condition of the tongue, if anything, worse. On June 2 100 mg. of calcium pantothenate was given intramuscularly and then 100 mg. daily by mouth.

By the third day discomfort had disappeared; by the seventh day only slight redness at the tip remained, and by July the organ was merely clean and atrophic. Calcium pantothenate was stopped on July 6, and from this date only routine liver therapy was given. Lingual discomfort returned within 14 days. By July 27 the organ was diffusely red and raw-looking, painful, and extremely sensitive, with numerous deep fissures. From July 27, 100 mg. of calcium pantothenate was given daily by mouth. By the fourth day undue discomfort could not be provoked even by hot foods or by deliberate friction against the teeth. By the seventh day objective evidence had almost entirely disappeared. By Aug. 17 the tongue looked more nearly normal than at any time since the patient had first been seen. Atrophy was less marked and central furring had developed. Fissuring was no longer present. Treatment with pantothenate was discontinued, and by March, 1947, there had been no recurrence of the glossitis.

Case 2

A married woman aged 40 had received liver therapy for two years, when the tongue, previously pale and atrophic became red and very uncomfortable. When seen with this complaint in February, 1946, blood values had been maintained for two years at normal levels (between 4,800,000 and 5,570,000 red cells per c.mm.). From Feb. 23, in addition to the continued regular administration of highly refined liver extract (anahaemin), 300 mg. of nicotinic acid was given daily by

nouth. Gradual improvement occurred, and by April 13 the only visible abnormality was slight marginal redness. The organ was still uncomfortable and unduly sensitive to hot foods. Continued treatment failed to improve matters, and nicotinic acid was stopped on April 27. She continued to receive regular injections of liver extract (anahaemin), but symptoms gradually returned. By Aug. 24 severe general glossitis was present. From this date she was given 100 mg. of calcium pantothenate daily by mouth. From the fourth day the tongue was comfortable, and by the seventh nothing abnormal was evident except slight atrophy. Treatment was stopped. Symptoms returned at beginning of November, and by the 23rd severe marginal glossitis was present, causing great discomfort. From this date she was given 100 mg. of calcium pantothenate daily by mouth. By the third day the tongue was almost completely asymptomatic. By the seventh day it looked almost normal, and by the 14th day it showed only a smooth atrophic veal-like condition. Treatment was stopped. Up to February, 1947, there had been no return of symptoms.

Case 3

A man aged 61 had received liver therapy for pernicious anaemia for nine months. His tongue had been normal in appearance and sensitivity during this period. In spite of continued regular treatment, and in the presence of blood values unchanged above 4,300,000 red cells per c.mm., from June, 1946, he gradually developed a painful glossitis. By July 27 the organ was diffusely affected and extremely sensitive and remained so without change until, from Aug. 24, 100 mg. of calcium pantothenate was given daily by mouth. Great subjective improvement was noted within 48 hours, and by the seventh day the organ was not even unduly sensitive. It was also normal in appearance. Calcium pantothenate was stopped, and up to March 15, 1947, there had been no return of symptoms.

Case 4

A married woman aged 58 had had a sore tongue before liver therapy was begun for pernicious anaemia in 1946, and during maintenance treatment which kept blood levels at above 4,500,000 red cells per c.mm. she suffered almost continuously. On June 7, 1946, after about two years' observation and treatment, the tongue showed a severe marginal glossitis with numerous sharp-edged fissures. It was extremely sensitive. By Aug. 3, in spite of continued treatment with liver extract, conditions remained unchanged. She was given 100 mg. of calcium pantothenate intramuscularly. Within 48 hours all discomfort had disappeared and within seven days signs had almost completely disappeared. Routine liver therapy thereafter failed to maintain this improvement, although the red cell count did not fall below 4,400,000 per c.mm.; but within five weeks of giving pantothenate the tongue had returned to its previous condition. On Oct. 6 a further 100 mg. of calcium pantothenate was given intramuscularly. Within 48 hours marked improvement had occurred, and by the seventh day all evidence of active glossitis had disappeared. Return of symptoms was evident in about three weeks, and by Nov. 2 active glossitis was again fully established. From this date 50 mg. of calcium pantothenate was given daily by mouth. By the third day the tongue was much less sensitive, and by the seventh day all discomfort had disappeared and the organ looked merely pale and atrophic. Treatment was stopped and conditions in the mouth remained unchanged for almost a year. In October, 1947, active glossitis again appeared, uninfluenced by continued regular administration of liver extract and with blood levels above 4,500,000 per c.mm. throughout. By Nov. 10 the tongue showed diffuse redness and was extremely sensitive. A simple dose of 50 mg. of pantothenate was given intramuscularly. Within 48 hours symptomatic relief was evident, and on the seventh day all redness had disappeared, but the tongue was atrophic. There had been no return of symptoms up to May, 1948.

Case 5

A woman aged 73 was admitted to hospital in April, 1944, on account of pernicious anaemia associated with severe glossitis and stomatitis. The tongue was diffusely red and

showed slight fissuring. The oral features were unaffected by liver therapy even when this was given twice weekly (4 ml. of anahaemin on each occasion). The blood count rose with a reticulocyte response in an unusually slow fashion, and throughout the following observation period the red cell levels failed to reach 4,000,000 per c.mm. Administration of 150 mg. of nicotinic acid daily by mouth from May 19, 1945, was followed by great improvement. By the seventh day the tongue was less sensitive and looked much less raw. The lips had healed completely. By the 14th day the tongue was merely atrophic and all discomfort had disappeared. Continuation of treatment for four months failed to improve the atrophy. After about two months' treatment with liver extract alone, active glossitis again became troublesome, and by February, 1946, the tongue had returned to its previous condition. On this occasion repetition of nicotinic acid treatment (150 mg. a day) was beneficial, but failed to relieve the condition completely. Treatment was stopped after three weeks, and 5 mg. of riboflavin was given daily by mouth from Feb. 28. Complete subjective and objective evidence of active glossitis disappeared within seven days. Treatment was stopped, and by June 3 symptoms had returned. On this date 100 mg. of calcium pantothenate was given intramuscularly. During the following 10 days the glossitis gradually became more severe. On Aug. 14 administration of riboflavin was again begun (5 mg. a day), with complete subjective and objective recovery by the seventh day. Further observations on this case were not possible.

Case 6

A married woman aged 58 was first seen on account of a sore tongue which had been troublesome for about two years. She was found to have pernicious anaemia. The tongue was diffusely red over the dorsum and very sensitive, although sensations of taste were impaired. From April 5, 1947, treatment with liver extract being withheld, 50 mg. of calcium pantothenate was given daily by mouth for seven days; no benefit resulted. After a further seven-day period of observation riboflavin was given in doses of 5 mg. daily for a week, again without benefit. Thereafter nicotinamide in daily doses of 200 mg. for two weeks was associated with slight aggravation of the glossitis. From May 10 folic acid was given by mouth in doses of 20 mg. a day. By the seventh day marked relief had occurred, and by the 10th day it was complete. By the 14th day the tongue was normal in appearance. A satisfactory haematological response also occurred with this treatment, and by Aug. 16 the tongue and the blood levels were normal. Folic acid was discontinued. Within four days the tongue became uncomfortable and active glossitis gradually progressed until liver therapy was begun on Aug. 23. Thereafter both anaemia and glossitis remained adequately controlled.

Case 7

This woman, aged 61, had been receiving liver therapy for five years, when she failed to receive adequate treatment and relapsed. During recovery from this relapse, with weekly administration of 4 ml. of anahaemin and with a red cell count of 3,410,000 per c.mm., she developed a very severe bilateral angular stomatitis involving the mucocutaneous junction, marginal glossitis, and vascularization of the cornea in the upper and outer quadrants, more pronounced in the left eye, where penetration of small vessels amounted to about 2 mm. There was also severe conjunctivitis. Treatment with riboflavin was begun on Dec. 28, 1946. Within a week the angular stomatitis and the conjunctivitis had improved, and by Jan. 25, 1947, the corneal change was seen to be receding. By Feb. 1 the tongue and lips were normal, and within a further 14 days the eyes also were normal. Riboflavin was discontinued after a short period. There was no return of symptoms.

Summary of Results of Treatment.—The results obtained by the administration of synthetic vitamins of the B complex to these patients are summarized in the accompanying table. No single substance was found to be effective throughout all cases, and although consistent results were obtained in the one individual with a single vitamin for periods up to 15 months (Case 4), it was also found in one

Table Summarizing Results of Treatment

Case No.	Sex	Clinical Status	Blood Level (Millions)	Lesions	Effective Treatment	* Vitamins Ineffective
1	M	Treated 4 months	4.5 +	Glossitis	Pantothenate, oral + i.m.	Nicotinic acid
2	F	Treated 2 years	4.8-5.8	"	Pantothenate, oral	Nicotinic acid (partial effect)
3	M	Treated 1 year	4.3 +	"	Pantothenate, oral	—
4	F	Treated 2 years	4.4 +	"	Pantothenate, (1) i.m., (2) oral	—
5	F	Treated 1 year	3.5-4.0	Glossitis, stomatitis	Nicotinic acid, riboflavin	Nicotinic acid later inadequate
6	F	Untreated	3.4	Glossitis	Folic acid	Pantothenate, nicotinamide, riboflavin
7	F	Treated 5 years	3.41 +	Glossitis, angular stomatitis, vascularization of cornea	Riboflavin	—

instance (Case 5) that different vitamins might be effective at different times against apparently similar lesions.

Discussion

The significance of glossitis in pernicious anaemia is not understood, but it is generally recognized that if sore tongue is a feature before treatment is begun it is usually cured by liver extract. Indeed, so commonly does the glossitis respond to liver extract that it has been said that reappearance of tongue manifestations in patients under treatment is an indication of inadequate therapy (Wintrobe, 1946). This suggests some direct relation between the glossitis and the anaemia. There is, however, evidence to the contrary (Oatway and Middleton, 1932; Brown, 1946).

In the present series glossitis occurred without obvious relation to present or subsequent blood levels (see Cases 1, 2, and 4 especially). The significance of this is not clear, especially in view of the apparent rarity of such an occurrence in the experience of others (Wintrobe, 1946). It seems unlikely from what is known of the individual patients that exceptional dietary inadequacy was by itself responsible. All had good appetites and were taking apparently adequate diets. The possibility of a combination of minor defect of absorption in pernicious anaemia and a sub-optimal post-war dietary cannot be entirely discounted. The question arises whether increased dosage with liver extract would have been effective treatment for the glossitis. No definite answer can be given from these results, which are concerned with the effect of single pure substances, but it should be noted that blood counts were maintained at normal and even high levels (Case 2), and in spite of this the tongue was sore. In addition Case 5 received unusually large doses of liver extract without effect on the tongue.

It would seem possible that the development of a sore tongue in pernicious anaemia reflects a breakdown in a metabolic system similar to that responsible for the megaloblastic marrow and the neurological changes. The fact that in this series the glossitis could be controlled by the administration of synthetic vitamins suggests that the breakdown may involve the availability of the vitamin found effective. Members of the B complex exist in natural foods often in a conjugated and not immediately available form. The suggested breakdown in availability may occur at this stage in assimilation, or later in closer relationship to their final functions as parts of enzyme systems concerned with cellular metabolism. Liver extract contains a factor which in the majority of cases rectifies the defect responsible for the mucosal changes and at the same time corrects those responsible for the marrow and neural disturbances. Vitamin B₁₂, which may be identical with the anti-pernicious-anaemia principle of liver, has been found effective against the anaemia, the neurological changes, and the glossitis. Conceivably this substance may promote the utilization of certain other essential substances, some of which are well-known vitamins of the B complex.

The role of pantothenic acid in human nutrition is not yet fully understood, and the instances described here are

believed to be the first in which this substance has been found to influence symptoms in pernicious anaemia. If this effect represents restoration of an actual deficiency it is difficult to account for the latter except on the basis of a metabolic disturbance secondary to a more fundamental defect such as that already suggested. Pantothenic acid is widespread in Nature, and a deficiency conditioned in such a way seems more probable than one due simply to inadequate intake, especially in persons whose diet is not obviously abnormal.

Summary

Seven patients with Addisonian pernicious anaemia are described each of whom had a sore, red, raw-looking tongue. One also had angular stomatitis and vascularization of the cornea.

In each case it was found possible to control these changes with a single member of the vitamin B complex in pure form. Four cases of glossitis responded to calcium pantothenate, and one each to nicotinic acid and folic acid. One case responded first to nicotinic acid and later to riboflavin. The patient with glossitis, angular stomatitis, and vascularization of the cornea responded to riboflavin.

The significance of these findings is discussed, and it is suggested that the epithelial changes described reflect a breakdown in some metabolic system which may be similar to that responsible for the megaloblastic marrow and the neurological complications of pernicious anaemia.

I wish to thank Professor L. J. Davis for his advice and criticism in the investigations and in the writing of this paper.

UNUSUAL SYMPTOMS IN PETROL-TANK CLEANERS

BY

INDER SINGH, M.B., B.S., M.R.C.P., F.R.F.P.S.
 Lieutenant-Colonel, I.A.M.C.

On Sept. 18, 1945, men from a certain labour unit were employed in cleaning a large petrol tank. It had just been drained of its contents, and to overcome the effects of undue exposure to the petrol vapour inside the tank the men were ordered to work in frequent shifts. The air inside the tank was not rendered gas-free, nor were the men given any airline masks or special clothing to wear. After the initial respiratory discomfort and irritation of the eyes the workmen became accustomed to the vapour and some of them stayed in longer.

Two men, whose cases are recorded below, went to the extreme and worked almost continuously for nearly seven hours. No adverse effects during this period prevented them from doing so. Towards the end, however, they

were seized with intense giddiness and they staggered and fell. They were rescued in an unconscious state by other workers. With first-aid measures both came round in about half an hour and complained of severe vertigo, a sense of constriction in the chest, and pains all over the body. They had to be carried to their quarters. The course of their illness was as follows.

Case 1

A man aged 25 was admitted to hospital the day after exposure to petrol vapour. Vertigo was severe and he complained of headache, marked loss of muscular power, soreness of the throat, irritation of the eyes, loss of appetite, and numbness, coldness, and intense pain in the lower limbs; pain in other parts of the body was less acute. Apart from congestion of the throat and eyes there were no abnormal physical signs.

6th Day.—The patient was improving. The calf muscles were, however, acutely tender on pressure. The knee- and ankle-jerks were sluggish. Five multivitamin tablets, each containing vitamin B₁, 1 mg., vitamin B₂, 1 mg., nicotinic acid, 10 mg., and ascorbic acid, 25 mg., were given three times a day.

10th Day.—Improvement was marked. Only slight pain remained in the lower limbs. Next day he was discharged as cured at his own request.

16th Day.—He returned to the hospital with headache, vertigo, and Parkinsonian tremor of both hands and early rigidity. He was irritable and irrational.

26th Day.—Parkinsonian rigidity and tremor were well established, and frequent oculogyric spasms were accompanied by spasms of the muscles of the face and mouth. His face, which was very pale, and his attitude, voluntary movements, and speech, were typical of the disease. Mental and bodily asthenia was profound, and most of the time the patient lay quiet in bed, showing no interest in himself or his surroundings. Rarely he asked for a bed-pan or urinal; mostly he passed his urine and stools in bed. His mood was very changeable, and he often cried without apparent reason. There was progressive loss of weight. The ankle-jerks were very feeble, but the calf muscles were not tender. The knee-jerks were slightly exaggerated and the abdominal reflexes were rather brisk. Heart sounds were very feeble. The pulse was regular, 72 a minute, and of low tension and volume. Blood pressure was 95/70 mm. Hg. Respiration was normal, and the temperature was usually subnormal. Both eyes were slightly icteric (effect of suppressive nepadrine). There was still conjunctivitis of the right eye. Urine showed no albumin, sugar, or abnormal quantities of lead, and deposits were normal. Stools were also normal. A blood count showed: Hb, 120% (Sahli); red cells, 6,830,000 per c.mm.; white cells, 12,600 (polymorphs 68%, lymphocytes 23%, nonnuclears 2%, eosinophils 1%, and basophils 6%). There were no malaria parasites in the smear. The bilirubin content of the blood was 0.7 mg. per 100 ml. (icterus index 3.5). Blood urea was 16.6 mg. per 100 ml. Wassermann and Kahn reactions were both negative. The patient weighed 118 lb. (53.52 kg.), having lost 23 lb. (10.43 kg.) since the onset of the disease. He was put on a nutritive high-protein diet of over 4,200 calories. In addition 10 multivitamin tablets were given thrice daily. Suppressant mepadrine was stopped.

36th Day.—For the first time during his stay in hospital the patient had a temperature of 100° F. (37.8° C.) at 6 p.m. Blood smears and thick drops were negative for malaria parasites. Subsequently the temperature was 99° F. (37.2° C.) at 10 p.m., 99.6° F. (37.55° C.) at 2 a.m. next morning, and once again normal at 6 a.m. and after. Between 1 and 10 a.m. he passed four samples of characteristic haemoglobinuric urine, the first very dark, the second and third dark brown, and the fourth considerably lighter. Subsequent samples were progressively normal to the naked eye, although spectroscopic examination showed the presence of oxyhaemoglobin till the next morning. Apart from the transient low fever described above there were no constitutional symptoms and no haemoglobinaemia in a blood sample taken at 10 a.m. Haemoglobin fell from 125 to 120%, and the red cells from 6,830,000 to 6,510,000 per c.mm. The leucocytosis was raised from 12,600 to 14,200, with polymorphs 72%, lymphocytes 20%, mononuclears 2%, eosino-

phils 1%, and basophils 5%. There were no malaria parasites in the smears or thick drop preparations. Spectroscopically, serum collected from blood taken at 10 a.m. with care to prevent haemolysis showed only traces of oxyhaemoglobin, and the icterus index remained at 3.5. There was no appreciable rise in blood urea. The Donath-Landsteiner reaction, the acid-serum test, and the Wassermann and Kahn reactions were negative. Spherocytosis was absent and fragility of red cells was normal. No haemolysins were found *in vitro* in the serum. Urine did not show any evidence of abnormal quantities of lead excretion. Alkalis and fluids were given by mouth, and, on empirical grounds, 20 ml. of concentrated antivenene was injected intramuscularly to prevent further haemolysis.

48th Day.—Improvement set in fairly rapidly. Rigidity and tremor were less pronounced. Headache, giddiness, and oculogyric spasms disappeared. His mood was less changeable and he was taking general interest all around. He was able to stand and to walk slowly by himself, and his weight had begun to rise. Insomnia still persisted.

76th Day.—The patient was now almost completely normal. A noticeable feature was a fall in his erythraemia; the red cells were now 5,200,000 per c.mm., and the Hb was 90%. The blood pressure was 120/80 mm. Hg. Insomnia was less troublesome. Mentally he was still moody and depressed.

96th Day.—He was discharged completely cured.

Case 2

A man aged 23 was admitted on the day after exposure to petrol vapour. His complaints and condition were essentially similar to those of Case 1, but vertigo was very severe and he had considerable pain associated with pins-and-needles in all parts of the body. The throat was very congested and there was conjunctivitis of the right eye. Unlike Case 1 there was no temporary improvement and the patient was completely bedridden.

13th Day.—He developed a Parkinsonian tremor of both hands, at first only when he attempted a voluntary movement, but two days later at rest also, with early rigidity. He was becoming very irrational.

26th Day.—His complaints were identical with those of Case 1, but he was more severely affected. Most of the time he was depressed and cried without any obvious reason. He talked of his family in trouble, which he said would finish without his help. Later he started getting out of bed and running away, and often fell and injured himself. He complained of the sisters and nursing orderlies harassing him, the loss of his pay-book although it was still with him, and a sense of impending death. He said he was guilty, and persistently begged for pardon for all the sins he had committed. There were physical signs of bronchitis at both bases. Heart sounds were very weak. The pulse was regular, 80 a minute, of low tension and volume. The blood pressure was 110/80 mm. Hg. Respiration was normal and the temperature was usually subnormal. Stools were strongly positive for ankylostoma ova. The urine contained no albumin, sugar, or abnormal quantities of lead, and deposits were normal. A blood count showed: Hb, 80%; red cells, 5,630,000 per c.mm.; white cells, 6,800 per c.mm. (polymorphs 62%, lymphocytes 26%, monocytes 4%, eosinophils 0%, and basophils 8%). There were no malaria parasites in the smears or thick drop preparations. The bilirubin content of the blood was 0.4 mg. per 100 ml. (icterus index 2). Blood urea was 53 mg. per 100 ml. Wassermann and Kahn reactions were negative. The patient weighed 130 lb. (58.97 kg.), having lost 28 lb. (12.7 kg.) in 26 days. Similar diet and multivitamin tablets were given as in Case 1.

38th Day.—The patient passed characteristic haemoglobinuric urine, sherry-red in colour, just after midnight. A second sample passed two hours later was lighter, and a third passed in the morning was almost normal. Subsequent samples were macroscopically normal, and before evening there was no spectroscopic evidence of oxyhaemoglobin in the urine. Constitutional symptoms and haemoglobinaemia in a sample of blood taken at 10 a.m. were conspicuous by their absence; the patient did not even have the little fever which occurred in Case 1. Spectroscopic examination of the blood showed only traces of oxyhaemoglobin, and there was no rise in the

icterus index. The blood count was not appreciably changed. The results of other tests as carried out in Case 1 were likewise all negative. Similar treatment was adopted.

48th Day.—The patient had an attack of severe abdominal pain below the umbilicus associated with tenderness in the right iliac fossa, vomiting, fever with rigor, and a leucocytosis of 13,200, with polymorphs 56%, lymphocytes 28%, monocytes 4%, and eosinophils 12%.

60th Day.—There were signs of improvement in the rigidity, tremor, and mental condition.

66th Day.—The patient complained of pain all over the body. He had haemoglobinuria again, and this time it was severer than that of Case 1. After midnight he passed three samples of very dark urine followed by urine of gradually diminishing colour. About twelve hours after the first sample was passed it had cleared considerably, but to the naked eye it was not completely clear until the evening. Once again there were no constitutional symptoms other than the preliminary aches and pains in the body, and no haemoglobinaemia about twelve hours after the first sample of haemoglobinuric urine, and the icterus index did not rise. The haemoglobin fell to 75%, and the red cells to 4,930,000 per c.mm. The white cells numbered 8,400 per c.mm., with polymorphs 68%, lymphocytes 23%, eosinophils 8%, and monocytes 1%. The results of blood smears and other tests carried out previously were all negative. Treatment similar to that in Case 1 was given; 10 ml. of concentrated antivenene was repeated next day also.

By the 80th day the patient had almost completely recovered, and on the 96th day he was discharged as fit.

A follow-up of both cases for twelve months showed that recovery was complete in all respects, and there had been no recurrence of haemoglobinuria.

Discussion

In general petrol is a mixture of hydrocarbons of varying volatility and toxicity, the toxicity decreasing as the boiling-point increases. Octane, which is present in high proportion in some petrols, is very toxic—e.g., n-octane is about seven times as toxic as pentane (Lawrence, 1945). Some commercial petrols contain benzene and other aromatic hydrocarbons which are of still greater toxicity. The amount of lead tetra-ethyl is normally too small to be toxic, but, in circumstances to be discussed later, may give rise to lead-poisoning.

The toxic symptoms which arise after the inhalation of petrol vapour depend on the concentration of the vapour and the duration of exposure to it—e.g., Fieldner, Katz, and Kinney (1921) found that 1 part per 1,000 produced drowsiness in men after 15 minutes' exposure, and vertigo, ataxia, and nausea at the end of one hour, but 7 parts per 1,000 produced definite intoxication in five minutes. A very high concentration of the vapour causes almost immediate unconsciousness, and death from respiratory arrest (Rambousek, 1913).

Ordinarily, exposure to low concentration of vapour produces emotional changes simulating those of drunkenness. There may be excitement or euphoric exhilaration. Tolerance may be acquired by repeated exposure, and in such persons tremor of the hands without any emotional changes may alone occur on exposure to low concentrations of the vapour (Hamilton, 1925; Kulkow, 1926). Women may burst into fits of uncontrollable hysterical laughter or crying. Men may become irritable and quarrelsome.

Higher concentrations irritate the eyes, the skin, and the respiratory passages. A sense of constriction in the throat, burning pain in the chest and abdomen, a feeling of pressure over the heart, and irritation of the skin are followed by drowsiness, headache, vertigo, nausea, and muscular weakness. Tonic contractions of flexors of the hands and twitchings of the muscles of the trunk and limbs have been described at this stage by Rudd (1944).

With still higher concentrations the euphoric exhilarative period is very short. The patient becomes rapidly disorientated and abusive. Hallucinations may occur and he may defy rescue and become rapidly delirious and comatose. Convulsions may occur, but may be delayed till he is removed to fresh air for resuscitation (Machle, 1941).

From short exposures recovery is quick and is followed by deep slumber from which he can be roused. After prolonged exposure coma may last several days and end in death from respiratory failure. Recovery from coma may be heralded by muscular twitchings, and is usually associated with severe headache, vomiting, severe abdominal pain, pain in the extremities, extreme restlessness, a bursts of hysterical laughter. Headache, insomnia, loss of appetite, vomiting, pain in the extremities and abdominal and muscular weakness are the usual immediate after-effects and may last several days. An early erysipelas-like eruption on the skin of the face and the mucous membrane of the mouth and throat followed by necrosis is an early fatal complication that rarely occurs (Floret, 1927).

Sometimes damage inflicted on the nervous system gives rise after a variable period to symptoms simulating those of disseminated sclerosis or other organic nervous diseases (Potts, 1915). The onset of epilepsy has been described by Floret (1927). Peripheral and cranial nerves may be involved, often singly, such as the sciatic (Jansen, 1912), hypoglossal, and optic. Recovery may take place or nervous disability may be permanent. Lawrence (1919) recorded the occurrence of discomfort and tenderness of the right iliac fossa on the second day after exposure to petrol vapour, lasting till the twelfth day, without an abnormal amount of lead in the urine or faeces.

Lead tetra-ethyl is readily soluble in fats and oils, hence poisoning can occur by its absorption through the intact skin. The chief mode of absorption is, however, through the pulmonary epithelium from inhalation of its vapour. In this form, the amount absorbed being proportionate to the vapour pressure in the lung alveoli. As much as 5% of lead per litre may be present in air saturated with vapour, and the symptoms of poisoning are entirely due to this lead content. Owing to the solubility of lead tetra-ethyl in fats, however, the central nervous system is chiefly affected.

The concentration of lead tetra-ethyl in leaded petrol is usually not more than 1 in 3,000 by volume, and in this concentration the occurrence of lead-poisoning is unknown in workmen engaged in its distributive and allied trades, as well as among the general public (Kehoe, Thamann, and Cholak, 1934; Final Report of Departmental Committee, 1930; Lind, 1936). It is unlikely that lead tetra-ethyl plays any part in the symptomatology of acute petrol-vapour poisoning, except when the exposure is prolonged and the concentration of lead in the air is more than the safe limit of 1.5 mg. per 10 m.³ of air (American Public Health Association, 1943). Thus under controlled conditions, when the concentration is kept below this limit, poisoning is hardly ever occurred in workmen engaged in the manufacture of the product and its blending with petrol (Kehoe, 1934; Kehoe and Machle, unpublished data, 1936).

No cases have been found in can-fillers and can-washers although the urine has contained from 0.026 to 0.6 mg. lead per litre (Cassells and Dodds, 1946).

These authors state that some of the men engaged in underground or semi-underground pump-houses, where ventilation was poor and the concentration of the vapour naturally higher, however, showed mild symptoms of intoxication and a urinary lead concentration which was as high as 0.275 mg. per litre. Workers in depots below the level of the surrounding countryside, and hence

with poor natural ventilation, showed a high urinary lead concentration but no symptoms of intoxication. However, 15 cases of poisoning are described in tank-cleaners who overlooked or disobeyed regulations governing the cleaning procedure. Machle (1935) had previously recorded 11 similar cases. In these the poisoning was due to inhalation of lead tetra-ethyl vapour in high concentrations rising out of the sludge or sediment deposited at the bottom of large tanks after storage for some time; these contained in analysed cases as much as 0.044 to 0.84% of organic lead compounds. Symptoms occurred after one to 17 days of exposure. "The classical signs and symptoms of lead-poisoning—namely, abdominal colic, tremors and fibrillary twitchings, myalgia, neuralgia, constipation, pallor, blue line on the gums, paralysis, stippling of the red blood cells, and punctate basophilia—either did not occur or were a very minor part indeed of the picture" (Cassells and Dodds, 1946), although in fatal cases the various organs showed a high concentration of lead—e.g., brain 0.6 to 1.74 mg., spleen 0.27 to 0.29 mg., liver 2.35 to 2.5 mg., kidneys 0.79 to 1.2 mg., against the normal maximum of brain 0.09 mg., spleen 0.07 mg., liver 0.28 mg., kidneys 0.16 mg. per 100 g. of wet tissue (American Public Health Association, 1943).

The earliest symptom was insomnia, with difficulty in falling asleep, broken sleep, and troubled dreams. Following this, and sometimes preceding it, came a nasty sweet taste in the mouth and halitosis, lack of appetite, nausea, vomiting, and diarrhoea with or without abdominal pain. Next in evidence were irritability, restlessness, nervousness, anxiety, difficulty in passing urine, and possibly tiredness. At this stage the pulse was slow, the temperature subnormal, the blood pressure diminished, and the reflexes increased, with the body weight showing slight loss. When exposure was longer and more severe "the signs and symptoms progressed to increasing tiredness and loss of body weight, tremor, muscular weakness and twitching, oddities of behaviour, and evidence of mental confusion, and then, quite abruptly, came the onset of acute maniacal symptoms with suicidal tendencies, or the occurrence of a convulsion" (Cassells and Dodds, 1946).

Although the classical signs and symptoms of lead-poisoning were absent urine examination showed a lead concentration which was usually above 0.15 mg. per litre. In fact, when the urinary lead concentration was less than 0.1 mg. per litre and symptoms of the above nature were displayed lead tetra-ethyl was considered unlikely to be the cause. The excretion of lead in the urine continued for a long time after exposure ceased, and sometimes the urinary concentration continued to rise in spite of cessation of exposure, to be followed by a progressive and gradual fall.

The clinical symptoms had apparently no relation to the urinary lead concentration—for in one of Cassells and Dodds's cases mental symptoms were present when the urinary lead concentration was 0.215 mg. per litre, but had disappeared later on when it had risen to 0.295 mg. Apparently loss of weight was sometimes very excessive, as shown in another of their cases by a gain in weight of 74 lb. (33.1 kg.) in about three months during the stage of recovery, and by a loss in a further case of between one and two stones (6–12 kg.) in about five weeks during the illness. Although the deep reflexes were usually exaggerated, at times they were diminished; in some cases they were exaggerated, while in others they were diminished—e.g., in one case "all reflexes were exaggerated except the biceps jerk, which was only just elicited." Cerebral symptoms in one case occurred suddenly in the midst of apparent recovery and ended fatally. There were no permanent sequelae: recollection of dreams was all that remained in one case.

Tropical conditions predispose to the occurrence of cases of lead tetra-ethyl poisoning. The two men whose cases are recorded in this paper were engaged, without any provision of airline masks or special clothing, in cleaning a tank which had not been rendered gas-free by ventilation after the petrol had been drained away. They thus faced a dual risk—one from the inhalation of petrol vapour, and the other from the absorption of lead tetra-ethyl by inhalation as well as by direct absorption through the intact skin.

The initial respiratory discomfort and irritation of the eyes were no doubt due to the effects of petrol vapour. It appears that sheer determination to work, associated with a fairly low concentration of the vapour, delayed the onset of giddiness, ataxia, and unconsciousness. To the effects of the same vapour may be ascribed the immediate symptoms, such as vertigo, headache, muscular weakness, anorexia, soreness of the eyes and throat, and pain in the lower limbs.

Symptoms of lead tetra-ethyl poisoning in a petrol-tank cleaner after exposure for a single working day have been described by Cassells and Dodds in one of the cases in their series, mentioned above. It will have to be conceded that these two workmen also absorbed enough lead during the day's exposure to give rise to such symptoms as marked loss of muscular power, muscular tenderness on pressure, and sluggish ankle- and knee-jerks due to its probable neuritic, muscular, spinal, or vasoconstrictor action. The numbness and the coldness of the lower limbs were perhaps due to vasoconstriction and the inability of the blood vessels to relax on account of the action of lead on them. Symptoms such as headache, anorexia, and body pains could be common to both effects.

Among the symptoms tremor, slow pulse, subnormal temperature, increased reflexes, loss of body weight, muscular weakness, and oddities of behaviour have all been described, as recorded above, in lead tetra-ethyl poisoning. It has been said that when symptoms of this nature are displayed lead tetra-ethyl is unlikely to be the cause if the urinary lead is less than 0.1 mg. per litre; yet on account of the similarity of symptoms it may be conceded that in my two cases these were due to lead tetra-ethyl in spite of failure to demonstrate pathological quantities of lead in the urine, and especially as in one of the cases there was no correlation between cerebral symptoms and the urinary lead concentration.

The unusual symptoms appearing in my two cases were:

1. *Acute Parkinsonism*.—As symptoms of organic nervous disorder are known to occur as sequelae of petrol-vapour poisoning it cannot altogether be ruled out that this was the case in these two patients. It is also known, however, that lead, through its vasoconstrictor action, can give rise to temporary blindness, angina pectoris, and gangrene of the extremities. Although localizing signs do not occur in lead encephalopathy, a similar selective action may play a part in the causation of acute Parkinsonism.

2. *Pain Simulating Acute Appendicitis*.—Discomfort and tenderness in the right iliac fossa, starting on the second day after exposure to petrol vapour and lasting until the twelfth day, recorded by Lawrence in one of his cases without any evidence of abnormal amounts of lead in the urine or faeces and apparently without any leucocytosis, bears a strong resemblance to an attack of similar pain in Case 2. However, in this instance it occurred 48 days after the exposure and was associated with a leucocytosis of 13,200 without a relative increase in the polymorphs. Such a leucocytosis is known to be associated with lead colic, and it is not impossible, therefore, that the appendicular reaction in this case was due to lead rather than to delayed effects of petrol vapour or to an incidental appendicitis.

not known. The incidence of 62% of *Staph. pyogenes* in the nasopharynx and its relative predominance is not unexpected in view of the findings of others (Kneeland, 1930; Torrey and Reese, 1945). The high incidence of 50% in the faeces is much greater than has been recorded heretofore (Todd, 1922; Crowley, Downie, Fulton, and Wilson, 1941), owing largely, it is believed, to the selective medium employed. It is a relevant point in considering the staphylococcus as a possible aetiological agent in enteritis.

The high incidence of penicillin-resistant strains in both nasopharynx and bowel probably reflects the strains circulating in a hospital environment. It is of interest that a similar incidence was found by Barber and Rozwadowska-Dowzenko (1948) from strains from infections, also in hospital. The figures obtained from this series of infants, taken in conjunction with time and place, may be regarded as a contribution to the further study of penicillin resistance of staphylococci in the community.

Summary

An investigation into the incidence of staphylococci in the nasopharynx and faeces of 130 normal healthy breast-fed infants aged 0-7 days born in the Maternity Department of St. Mary's Hospital, Manchester, is recorded.

From the nasopharynx *Staph. pyogenes* was isolated in 62% of the infants and from the faeces in 50%.

Of the *Staph. pyogenes* strains isolated from the nasopharynx 55.5%, and from the faeces 58.5%, were penicillin-resistant. All the resistant strains produced penicillinase.

Only four strains of *Staph. pyogenes* isolated were resistant to streptomycin.

In the cases that were specially tested there was homogeneity in the staphylococcal flora of the nasopharynx and bowel in individual infants so far as sensitivity to penicillin was concerned. In three-quarters of the infants who harboured *Staph. pyogenes* in both nasopharynx and bowel the strains from the two sources corresponded in their susceptibility to both penicillin and streptomycin.

The high incidence of *Staph. pyogenes* in the faeces was due largely to the use of a selective medium, and the high incidence of penicillin-resistant strains probably reflects the strain circulating in the hospital.

I wish to thank Professor W. F. Gaisford for his interest and advice and Professor H. B. Maitland for helpful criticism.

This work was undertaken whilst holding the Cow and Gate Research Fellowship in Child Health tenable in the Department of Child Health, University of Manchester.

The Ministry of Health has issued a circular describing the procedure to be followed in caring for persons of unsound mind arriving at seaports and airports. If a British subject of unsound mind is not met by a relative or friend who will take charge of him, the medical officer there should call in the appropriate duly authorized officer of the local health authority, who is responsible for removing a person of unsound mind. An alien of unsound mind is prohibited by the Aliens Order, 1920, from being given leave to land, but Article 14 of the Order enables the Secretary of State to exempt any person from that prohibition. An immigration officer who considers that an alien is of unsound mind should seek the advice of the Medical Inspector of Aliens. If the latter is satisfied that the alien is of unsound mind, he gives the appropriate certificate on Form Port 12 to the immigration officer. If, nevertheless, the alien is allowed to land, the immigration officer is responsible for his disposal, and he may then deal with him in the same way as for a British subject.

Medical Memorandum

Unusual Physical Signs in Strangulated Inguinal Hernia

The following case of strangulated inguinal hernia is recorded because it illustrates three physical signs which should receive wider recognition.

CASE REPORT

A normal healthy man aged 33 was admitted to hospital complaining of a swelling in the right groin and vague abdominal pain. The swelling in the groin had been present for about six weeks and had not given rise to any symptoms until three days before admission when it became painful and enlarged rapidly, extending into the scrotum. He complained of some generalized abdominal pain of colicky nature, a little nausea, and constipation for two days. He was also reported that blood-stained fluid had been aspirated from a hydrocele on the right side some hours previous to admission.

On examination a large fusiform swelling was seen in the right groin, extending downwards and continuous with a very large swelling in the right half of the scrotum. It was impossible to get above the swelling in the groin, yet the swelling of the scrotum was clearly cystic and translucent, although not brightly so. There was a gurgling cough impulse over the swelling in the groin. Auscultation of the abdomen revealed some increase of peristaltic sounds, and the heart sounds could be clearly heard throughout the whole abdomen.

At operation a loop of ileum was found to be strangulated at constriction about half-way down an hourglass-shaped hernial sac. About 6 in. (15 cm.) of bowel was involved, and the distal sac, which was very large, was filled with dark blood-stained fluid. Considerable ascites was present in the abdominal cavity, with moderate intestinal distension.

The strangulated bowel was thickened, waterlogged, and dark purple in colour, and the mesentery was thrombotic and oedematous. After the usual measures to restore the circulation it was decided to resect the bowel, and a piece about 2 ft. 6 in. (76 cm.) was removed and an end-to-end anastomosis performed. The large congenital sac was removed and the hernia repaired. The patient made an uninterrupted recovery and at a follow-up three months later had no complaints.

COMMENTARY

The Cough Impulse.—In a case of suspected strangulated hernia the presence of a cough impulse should not necessarily rule out the diagnosis. As in this case, the site of strangulation may be some way distal to the external abdominal ring leaving the proximal part of the contents unstrangulated.

Blood-stained Hydrocele.—The collection of blood-stained fluid from a hydrocele is usually considered to be associated with some disease or trauma of the testis. The above case demonstrated that it may be associated with intestinal obstruction. Such a finding was of even greater interest in another case I had some years ago. A man presented with a recent developed hydrocele of a hernial sac with blood-stained fluid. On lying the patient down it was found that the sac could be slowly emptied into the peritoneal cavity—i.e., the processus vaginalis was patent. At operation an internal strangulation due to a fibrous band was found. At no time had he ever noticed any descent into the hernia—the congenital sac being always there, but making itself manifest only when blood-stained fluid formed within the abdomen.

Heart Sounds Heard Clearly in the Abdomen.—This fact, believe, signifies a combination of intestinal distension and fluid. I have heard the sounds on other occasions, and these findings have always been confirmed at operation or strongly supported by other signs.

In the case recorded the fluid in the abdomen was undoubtedly present because the strangulation was of that type which starts with slow venous occlusion, as shown by the thickened waterlogged loop of strangulated bowel in contrast to the thin friable type of wall found in more rapid strangulation in which the arteries are quickly occluded. Although in the former type of obstruction I believe the bowel is often more viable than its appearance would suggest, it is this type of strangulation which leads to late obstruction from interstitial fibrosis at constriction if the bowel is dropped back.

If the patient's condition warrants it, an immediate resection would always seem justified.

Reviews

CARE OF CHILDREN

Advances in Pediatrics. Volume 3. Edited by S. Z. Levine, A. M. Butler, L. E. Holt, jun., and A. A. Weech. (Pp. 363; illustrated. £2 5s.) New York and London: Interscience Publishers. 1948.

Handbook of Parentcraft. By Leslie George Housden, O.B.E., M.D. With an Introduction by Sir Wilson Jameson, K.C.B., F.R.C.P., D.P.H. (Pp. 152. 5s.) London: Eyre and Spottiswoode, 1948.

The third volume of *Advances in Pediatrics* is up to the high standard set by its predecessors. Eight monographs, each with useful bibliographies, cover a wide range of interests. It is significant of the present-day trend that two of the eight are on psychological matters. The account of the treatment of epilepsy and the social management of children with this complaint is a practical contribution of great importance. A thoughtful essay on the effects of birth processes and obstetric procedures on the newborn infant is a worthy product of the Boston School, from which comes also an account of retro-lental fibroplasia, posthumously contributed. From Philadelphia the pen of an expert deals with viral hepatitis, and the contribution from Johns Hopkins is on abnormalities of sexual development, a study which was presented in graphic form at the International Congress on Pediatrics in 1947 in New York. A concluding essay on the osteochondroses is a comprehensive account of this curious group of bony abnormalities. The reviewer's only regret is that a year must elapse before more surveys of this type are available.

Dr. L. G. Housden's little volume on parentcraft makes available in permanent form the teachings of this keen enthusiast. His general thesis is perhaps sounder than some of his details. Pasteurized milk is not generally regarded as safe for babies without boiling, and the milk dilutions advocated (with the briefest mention of dried milk) are not those generally accepted. However, Dr. Housden's object is to educate young parents in their job, which is a larger and more important theme than bottle feeding, and he has certainly succeeded in writing an interesting book.

ALAN MONCRIEFF.

PSYCHOLOGY OF CHILDREN

Childhood and After. Some Essays and Clinical Studies. By Susan Isaacs, C.B.E., M.A., D.Sc.(Vict.), Hon.D.Sc. (Adelaide). (Pp. 245. 15s.) London: Routledge and Kegan Paul. 1948.

With the death of Susan Isaacs we have lost one of the foremost pioneers of child psychology and one whose originality of thought and powers of observation are all too uncommon in this or any other field of mental science. An early adherent of the psycho-analytic school, she may have been regarded by some as too extreme in her early days, but later she became a wise counsellor whose knowledge and understanding of the inner workings of the human mind made her a real help to the community.

This development is reflected in this book, which is a collection of lectures and addresses some of which have not previously been published. One of the early essays—that on privation and guilt (1929)—is full of the extreme Freudian ideas—the Oedipus complex, the castration complex, infantile sadism, and so on. That there are at times waves of hostility to the mother and still more to the father in the mind of the young child, and that these moods may influence subsequent behaviour, may readily be accepted, but that specific desires to tear the mother to pieces, to destroy her and eat her, are ever formulated even in the deepest layer of the unconscious is less credible, though the hostility may later be expressed in some such way during psychotic fantasies. In a later essay (1940) on temper tantrums we find a less extreme attitude when the author is discussing tantrums in young children, but she returns to somewhat extravagant Freudian explanations in respect of the emotional outbursts of a young schizoid adult.

The last two essays—on fatherless children and children in institutions—are wholly admirable—sensible, instructive, and constructive. The last is the full text of a memorandum

to the Curtis Committee and must have influenced and impressed that body considerably. This volume is of great interest in showing the development not only of the author's mind but also of the whole modern attitude to abnormal psychology.

R. G. GORDON.

HODGKIN'S DISEASE

Hodgkin's Disease and Allied Disorders. By Henry Jackson, jun., A.B., M.D., and Frederic Parker, jun., A.B., M.D. Oxford Medical Publications. (Pp. 177; 14 plates. £2 5s.) New York: Oxford University Press (Geoffrey Cumberlege). 1947.

This attractively produced monograph embodies the authors' observations on a series of 259 cases of Hodgkin's disease. The "allied disorders" discussed successively in shorter sections are reticulum-cell sarcoma, giant-follicle lymphoma, lymphocytoma, lymphosarcoma, plasmacytoma, and endothelioma. The authors describe all these conditions from their combined clinical and pathological aspects and illustrate them by radiographs and photomicrographs.

While the text is full of interesting and authoritative observations which will be of value to the practising specialist and pathologist, there is nothing revolutionary in these pages. The most controversial aspect of the account of Hodgkin's disease, perhaps lies in their distinguishing three forms of the condition—*paragranuloma*, *granuloma*, and *sarcoma*. The authors consider that each of these displays a distinctive pathological and clinical picture. While "paragranuloma" has been regarded by others as "early Hodgkin's disease," the authors claim that, although it may pass on to the granuloma phase, it may persist unchanged for many years, and they quote an instance where the patient is alive and active 39 years after the diagnosis was established by biopsy. The paragranuloma and granuloma together conform to the prevailing conception of Hodgkin's disease. It may be, however, that some examples at least of the paragranuloma are rather to be regarded as the equivalent of Robb-Smith's lympho-reticular medullary reticulosis.

The interpretation of what is called Hodgkin's sarcoma is a difficulty that confronts all pathologists; we read (p. 32) that the spleen was involved in only 9 of 32 cases, but it seems likely that this group would be broken down by other authorities into different categories. Doubtless this and other controversial points will be resolved only when the aetiology of the disease is known.

DOROTHY S. RUSSELL.

ANALYTICAL PSYCHOLOGY

Studies in Analytical Psychology. By Gerhard Adler, Ph.D. (Pp. 209; illustrated. 21s.) London: Routledge and Kegan Paul. 1948.

The contributions of C. G. Jung to psychiatry and psychopathology are so extensive that a summary of some main concepts is welcome. The summary presented in this volume is given in the setting of clinical experience, and in consequence the account is vivid and avoids the dullness of an epitome. It is not a book for the beginner. Throughout the author assumes that the reader is familiar with the terminology of analytical psychology and psycho-analysis.

In the opening chapter, "A Comparative Study of Analytical Psychology," the author criticizes chiefly the Freudian point of view, and he competently discusses the differences between the teaching of Jung and of Freud. The exposition of Jungian theory and clinical procedure in the later chapters is more useful and gives the book its practical value. Psychiatrists have the unusual opportunity of observing a colleague at work and noting just how he tackles the well-known problems. Now and then, however, the author's enthusiasm outruns his critical faculty and we find a tendency to generalize from particular instances. It is probably true, for example, that some—perhaps many—children go through ceremonies with their dolls and animal toys before going to sleep in order to allay dimly felt anxiety of the powers of darkness. But not every child is afraid of the dark, and not every child who says good night to its doll is carrying out a protective ceremony customary in primitive races (p. 101).

Drawing and painting have been used for years in psychiatry as a form of diversional therapy, but their use in expressing

hitherto unrecognized thought and feeling, for which no other vehicle will serve, is more recent. The illustrations in this volume, drawn by the author's patients in an attempt to understand their dreams, are of this type, and the commentary upon them is clear and informative. The final chapter, on "Jung's Contribution to Modern Consciousness," takes us beyond the limitations of psychiatry and describes how much psychology as a whole has gained by Jung's teaching. The book is worthy of serious attention and will be of special interest to post-graduate students who require a lucid statement on such subjects as symbolism, the collective unconscious, archetypes, amplification, the opposites, and dream analysis.

TELEKINESIS

The Reach of the Mind. By J. B. Rhine. (Pp. 188. 10s. 6d.) London: Faber and Faber. 1948

Psychology is indebted to Professor Rhine for his pioneer scientific work on telepathy, clairvoyance, and, most recently, telekinesis. This work, extensively confirmed elsewhere, could not be seriously discussed until the combination of controlled experiment and statistical analysis showed, as it now has done, that effects are being obtained which cannot be accounted for by any present theory of mental and physical interaction. They demand further inquiry. The late Sir James Jeans once remarked that any experiment should be regarded with the greatest caution until it was confirmed by theory. This is the present standing of these studies of "psi" phenomena. The reader receives the impression that Professor Rhine is studiously avoiding the statement of any working hypothesis and that he is best pleased when the results of experiment are apparently senseless.

He has, for instance, performed a great number of experiments on the power of his subjects to influence the fall of rolling dice, and he shows that they can at will secure an excessive proportion of high or of low numbers on the top faces of the dice when they have come to rest. He has experimented with dice of various shapes—e.g., with sharp or rounded edges—and found no difference between them. Telekinesis is unaffected by such mechanical factors. He also says, however, that he gave up experimenting with disks because he got no statistically significant results; so it seems that the shape of these experimental objects does have some effect after all. If mental operations have some direct effect on isolated physical systems, then they must be to some extent subject to the laws of physics; if Professor Rhine has not found this, it may be because he has not looked in the right direction. If his views are correct, there is no reason why the pure willing of one of his subjects should not be able to roll over a single dice after it has come to rest and turn it so as to show another face. A single successful experiment of this kind would be a clearer demonstration to the vulgar than a thousand experiments whose validity depends on statistical analysis.

Professor Rhine is enthusiastically concerned to demonstrate the paramouncy of mind and the "psychocentric" nature of man, as well as to dethrone materialist systems of philosophy. Although the phenomena he reports are extremely interesting, their theoretical interpretation is still so doubtful that no radical change in the basic philosophy of science seems yet to be called for.

ELIOT SLATER.

Dr. Frederick Christopher's *Minor Surgery* (sixth edition, pp. 1,058; 937 illustrations on 595 figures; £3. Philadelphia and London: W. B. Saunders) includes much more than is usually found in the house-surgeon's manual. As the author points out, the distinction between minor and major surgery is at times almost impossible to make. He has overcome this difficulty by giving the term a comprehensive meaning. As a result the book will be useful not only to the newly elected house-officer but to the majority of practitioners and assistant surgeons. This edition has been brought thoroughly up to date. Indeed, the author considers such procedures as the use of oxidized cellulose for the control of haemorrhage and others which have not yet established themselves, but he always gives references to recent work. The chapters on the surgery of the extremities make the book a useful treatise on minor orthopaedic work—perhaps as good as is to be found anywhere. This book has always been popular; in its new revised form it is likely to be more so.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

A Course in Practical Therapeutics. By M. E. Rehfuss, M.D., F.A.C.P., and others (Pp. 824. 82s. 6d.) London: Baillière, Tindall and Cox. 1948.

Systematically arranged and fully illustrated.

The Diagnosis of the Acute Abdomen in Rhyme. By Zeta. 2nd ed. (Pp. 93. 6s.) London: H. K. Lewis. 1949.

A second edition of the well-known epic.

An Introduction to Public Health. By E. W. Caryl Thomas, M.D., B.Sc., D.P.H. (Pp. 263. 15s.) London: Simpkin Marshall. 1949.

A short book for students.

Cunningham's Manual of Practical Anatomy. By J. C. Brash, M.C., M.A., M.D., F.R.C.S.Ed., F.R.S.Ed. Vol. 1. 11th ed. (Pp. 387. 21s.) London: Geoffrey Cumberlege. 1948.

General introduction, and the upper and lower limbs

Pediatric Anesthesia. By M. D. Leigh, M.D., and M. K. Belton, M.D. (Pp. 240. 27s. 6d.) London: Macmillan. 1948.

Theory and practice of anaesthesia for children

Eat and Grow Beautiful. By G. Hauser. (Pp. 233. 9s. 6d.) London: Faber and Faber. 1949

A book for the non-scientific reader.

Practical Orthoptics in the Treatment of Squint. By T. K. Lyle, M.A., M.D., M.Chir., M.R.C.P., F.R.C.S., and S. Jackson, S.R.N., D.B.O. 3rd ed. (Pp. 271. 35s.) London: H. K. Lewis. 1949

An extensively revised edition.

Common Sense About Hair. By G. Reeson, M.I.T., and C. Bedeman, M.I.T. (Pp. 78. 3s. 6d.) London: Walding Press. 1949.

For the layman

Psycho-Analysis Today. Edited by S. Lorand, M.D. (Pp. 404. 25s.) London: George Allen and Unwin. 1948.

A survey of the development of psycho-analysis.

La Marilynana en la America Latina. By P. O. Wolff (Pp. 55. No price.) Buenos Aires: El Ateneo. 1948.

Extended version of a lecture given to the Medico-Legal Society of Buenos Aires.

The Neurosis of Man. By I. Burrow, M.D., Ph.D. (Pp. 428. 28s.) London: Routledge and Kegan Paul. 1949.

An analysis of the causes of neurosis

Klinische Infektionslehre. By F. O. Höring. 2nd ed. (Pp. 245. M. 18.) Berlin: Springer. 1948.

A study of the pathogenesis of infection.

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Edited by C. F. Mayer, M.D. (Pp. 994. \$4.25.) Washington: U.S. Government Printing Office. 1948.

The tenth volume of the fourth series, which is also the fifty-seventh volume of the entire publication since its inception in 1880.

Anaesthetics and the Patient. By G. Ostlere, D.A. (Pp. 166. 7s. 6d.) London: Sigma Books. 1949.

A monograph for nurses, junior medical students, and the layman.

Yearbook of General Surgery, 1948. Edited by E. A. Graham, M.D. (Pp. 717. 25s.) London: H. K. Lewis. 1949.

A review of the year's literature.

First Steps in Childhood. By G. M. Kerr, M.B., B.S., D.A. (Pp. 120. 3s. 6d.) London: Clerke and Cockran. 1949

For mothers.

Tuberculosis of the Knee-Joint. By J. Mortens. (Pp. 550. Kr. 30.) London: H. K. Lewis. 1948.

English translation of a recent Danish monograph.

BRITISH MEDICAL JOURNAL

SATURDAY APRIL 23 1949

THE SYMPATHETIC TRANSMITTER

Adrenaline is an amine in which one hydrogen atom is replaced by a methyl group; the same amine in which this hydrogen atom is not replaced is known as nor-adrenaline or arterenol. Evidence is accumulating to show that the substance which transmits sympathetic impulses to the end organ is nor-adrenaline, and not adrenaline as many have thought. Several workers¹⁻⁴ have obtained results indicating that nor-adrenaline is the transmitter at sympathetic nerve endings in the liver. Recently von Euler⁵ has demonstrated by colorimetric and biological tests that extracts of sympathetic splenic nerve fibres of cattle contain 1-nor-adrenaline—a finding which again emphasizes the importance of this substance. To be set in the balance against this evidence is that of Gaddum and his colleagues,^{6, 7} who found the substance liberated by the stimulation of sympathetic nerves to the vessels of the rabbit's ear to be adrenaline.

All this work might seem at first sight to be of academic importance only, but Goldenberg and his colleagues⁸ in the U.S.A. have been quick to see its possible clinical significance. They have made a clinical study of the effects of intravenous infusion of nor-adrenaline, comparing them with those of adrenaline. The vasodilator effect of adrenaline has been demonstrated in man by Allen, Barcroft, and Edholm⁹ and by other workers.¹⁰⁻¹² The action of nor-adrenaline is different: intravenous infusion causes vasoconstriction and a rise in pressure. For example, in one patient Goldenberg and his colleagues found that infusion of adrenaline caused a fall in the total peripheral resistance (expressed in dynes cm.⁻⁵ sec) from 1,000 to 500, the infusion of nor-adrenaline on the other hand caused a rise from 1,250 to 1,750. When both adrenaline and nor-adrenaline were infused there was a fall; the presence of adrenaline appeared to block the constrictor action of nor-adrenaline. From these and similar observations in other patients they put forward the highly speculative theory that essential hypertension may be considered to be a disease of deficient transmethylation, though they admit that their study provides no "definitive evidence" for this view. They suggest, that is, that nor-adrenaline is a precursor of adrenaline, and that essential hypertension results from a failure to effect the conversion. Recently Holtz and Kroneberg¹³ put forward the view that epinine rather than nor-adrenaline is the precursor of adrenaline.

Obviously, until there is evidence that nor-adrenaline can become adrenaline by methylation, the theory, however interesting, must remain insecure. The difference between nor-adrenaline and adrenaline is not confined to the action on the vessels, for Barcroft and Konzett¹⁴ have shown that intravenous infusion in man of nor-adrenaline causes a slowing of the heart rate, while that of adrenaline causes a quickening.

If nor-adrenaline is the sympathetic transmitter and is a purely constrictor substance, how then is sympathetic vasodilatation to be explained? It has been known since the time of Dastre and Morat¹⁵ that the stimulation of certain sympathetic fibres produces vasodilatation. The experiments of Bulbring and Burn¹⁶ threw light on sympathetic vasodilatation in the dog. They found that the vasodilatation was due to the liberation of acetylcholine. Folkow and Uvnäs¹⁷ in Sweden have now studied sympathetic vasodilatation in the cat and have come to the conclusion that in this animal as well as in the dog the transmitter is acetylcholine. They and their colleagues¹⁸ have also shown that the sympathetic vasodilator fibres in the coronary vessels liberate acetylcholine. They regard nor-adrenaline as the transmitter of all constrictor impulses in the cat and acetylcholine as the transmitter of all sympathetic dilator impulses.

The most recent observations on nor-adrenaline concern the medulla of the suprarenal gland. Holton¹⁹ has shown that medullary tumours contain much more nor-adrenaline than adrenaline. Meier and Ben²⁰ have found that the dilator action of adrenaline on the limb vessels disappears if the suprarenal glands are removed, but it reappears if nor-adrenaline is infused intravenously, thus they suppose that the suprarenal medulla must liberate not only adrenaline but also nor-adrenaline. Schümann²¹ has reported the presence of nor-adrenaline in the suprarenal of the pig. Bulbring and Burn²² have shown that stimulation of the splanchnic nerve in the cat liberates from the suprarenal medulla a mixture of nor-adrenaline and adrenaline—on an average about 50% of each. Thus nor-adrenaline is rapidly becoming a substance of unexpected importance, and the rate at which new discoveries in this field are appearing is so great that conclusions of clinical interest seem bound to emerge very soon.

DIPHTHERIA PROPHYLACTICS

From 1911 to 1940 the number of cases of diphtheria notified in England and Wales was consistently round about 50,000 a year. In 1940 the Ministry of Health introduced its immunization scheme—the prophylactic most commonly used being alum-precipitated toxoid (A.P.T.)—and in 1942 the number of notified cases was 41,404; after that it fell steadily—34,662 in 1943, 29,949 in 1944, 18,596 in 1945, 11,986 in 1946, and 3,941 in 1947, the last year

for which full returns are available. The number of deaths from diphtheria showed a similar trend: between 1911 and 1940 there had been a fairly steady fall, but the figure appeared to be attaining stability at about 2,500 (2,133 in 1939, 2,480 in 1940, 2,641 in 1941). In 1942, two years after the Ministry's campaign had started, deaths from diphtheria in England and Wales had fallen to 1,827, and the decrease continued: 1,371 in 1943, 934 in 1944, 722 in 1945, 472 in 1946, and 198 in 1947.

Since this remarkable change in the incidence and mortality of diphtheria took place to a large extent during a war in which food shortages, movements of population, and bombing had added greatly to the difficulty of controlling infectious disease, it is clear that A.P.T. possesses the essential feature of a good diphtheria prophylactic—the capacity to reduce to very small proportions the incidence and mortality of diphtheria. Recently, however, some disquiet has been expressed at the variability of A.P.T. as an immunizing agent.¹ Much of this seems to have been due to the use of some preparations of low potency in the 1941 immunization campaign. Though batches of A.P.T. produced by the method of Barr, Glenny, Pope, and Linggood² show little variation in antigenic power in guinea-pigs, whether tested by a one- or two-dose method,³ there is clearly some substance in the contention that the composition of A.P.T. is not accurately known, that it is not reproducible with certainty in different laboratories, and that the amount of carrier (according to Holt,⁴ aluminium hydroxide and phosphate) cannot be controlled. There is also some complaint of reactions after A.P.T., particularly in older children and in adults; these are said to be due partly to bacterial protein in the prophylactic. Obviously, therefore, it would be a great advantage to have a diphtheria prophylactic the composition of which was constant and controllable and which caused few reactions—always provided that the immunizing effect was at least as good as that of A.P.T.

These considerations led Mr. L. B. Holt to devise a new prophylactic,⁴ and to this he gave the name P.T.A.P. (purified toxoid, aluminium phosphate precipitated). The purified toxoid, produced from the toxin of *C. diphtheriae* grown in a semisynthetic medium, is precipitated by the addition of aluminium phosphate in controlled conditions.⁵ By this method toxoid of consistent purity can be adsorbed on known and controllable amounts of aluminium phosphate. The latter point is of considerable importance, since Bousfield⁶ has shown that if a constant amount of toxoid is injected as P.T.A.P. the Schick-conversion rate rises with increase in the amount of carrier used. When testing P.T.A.P. by a one-injection method in children Bousfield and his colleagues⁷ found that different batches did not vary in antigenic potency, that the Schick-conversion rate by this method was from 94.1% to 100%, and that the antigenicity of P.T.A.P. improves on keeping. Reactions¹ to P.T.A.P. are reported to be trifling in children and in adults, and in individuals sensitive to A.P.T. are less than those

caused by the latter prophylactic. (Complete freedom from reaction to diphtheria prophylactics is hardly likely to be achieved: Pappenheimer and Lawrence⁸ have shown that some individuals are sensitive to pure diphtheria toxoid.) Nodule formation becomes more obvious as the dose of carrier is increased, and the Schick-conversion rate tends to rise as the incidence and extent of nodule formation become greater.

In this issue of the *Journal* Mr. L. B. Holt and Dr. Guy Bousfield give an account of the present position of P.T.A.P. First, they show that there is no significant difference between batches of P.T.A.P. of the same age as judged by the Schick-conversion rate in children 28 days after a single injection. They also found no difference between the six batches of A.P.T. tested in parallel, but P.T.A.P. did give a significantly higher mean value for the Schick-conversion rate (96.6%, as compared with 87.5% for A.P.T.) 28 days after one injection. They then consider the method of injection, and show that if 5 Lf doses of toxoid are used as antigen in a single dose intramuscular injection gives a higher Schick-conversion rate than subcutaneous injection whatever the quantity of carrier, presumably because muscular movement not only may disperse the antigen but also delays its encapsulation. There is evidence that 5 Lf doses of toxoid adsorbed on 5 mg. aluminium phosphate give the best results. An interesting finding is that even with such small doses of toxoid (15 Lf doses plus 7.5 mg. AlPO_4) a Schick-conversion rate of 95% may be obtained three months after a single intramuscular injection. Moreover, even with this small dose the Schick-negative state is maintained in at least 95% of the children for at least 15 months. The authors suggest that these observations indicate that a prophylactic effective against diphtheria by a single injection may be practicable—a matter of obvious importance, since many children never appear for their second injection. At present, however, there are still strong theoretical objections to giving the first course of immunization by a single-dose method. The earlier batches of P.T.A.P. (at pH 5) produced some stinging on injection, but it was found that adjustment to pH 6.5–7 not only abolished the stinging but made no difference to the antigenicity. From their experience so far Holt and Bousfield recommend a prophylactic containing in .1 ml. 50 Lf doses of toxoid (2,000 Lf doses per mg. protein nitrogen), 10 mg. of AlPO_4 , 0.85 g. of NaCl , and 0.0001 g. of preservative, adjusted to pH 6–6.5 and stored for three to six months in the cold-room before issue.

This work shows what advances have been made in the study of diphtheria prophylactics. There is, however, still a need for caution: the test of a diphtheria prophylactic is its efficiency in the field—its capacity to reduce to a negligible level the incidence of diphtheria and its mortality. Large amounts of bacterial protein in prophylactics undoubtedly increase the frequency and severity of "reactions" after injection; removal of all bacterial protein, though it reduces reactions to a minimum, may reduce the immunizing power even though the Schick-conversion rate is raised. It is therefore exceedingly important that extensive trials of the immunizing power of this new prophylactic should be carried out, preferably over a number of years, in parallel with A.P.T. If the incidence of

diphtheria in children injected with P.T.A.P. is as low as, or lower than, the incidence in those injected with A.P.T. then the case for P.T.A.P. will have been conclusively proved.

AN UNFORTUNATE PRECEDENT

Lord Moran was last week re-elected President of the Royal College of Physicians of London and thus enters his ninth year in this distinguished office. President during a time of storm and stress, he has by his skill in negotiation rendered the profession notable service. Lord Moran has been at the head of affairs longer than any recent presidents, the nearest to him in duration of office being Lord Dawson of Penn, who was P.R.C.P. for seven years. There is, of course, no fixed term of office, the election being annual. But a glance at the history of the College shows that some former presidents had considerable staying power. For example, William Baronsdale (1589-99) and Sir Edward Alston (1655-66) each served for a term of 11 years. Sir Hans Sloane, founder of the British Museum, was President for 16 years, from 1719 to 1735. The president longest in office was Sir Henry Hallford, who was elected unanimously every year from 1820 to 1844. He was physician to four sovereigns, and mainly responsible for the removal in 1825 of the College from Warwick Lane to its present habitation in Pall Mall East.

Politics and economics now invade professional life and thought in a way that would have made our ancestors sit uneasily in their chairs of office. Presidents now have to bear a heavy burden and responsibility. As guardians of the gates of ancient and learned institutions they have, Janus-like, to look two ways at once, within and without, at the internal affairs of the Colleges and at the external relations between these and the State. This dual obligation is illustrated by the fact that the present President of the Royal College of Physicians is also the Chairman of the Distinction Awards Committee, a committee which has the difficult—and, as some think, impossible—task of selecting from the body of consultants and specialists in this country those thought fit to receive money prizes. It says much for Lord Moran's strong sense of duty that he has consented to act in these two capacities; and that the Comitia of the College last week re-elected him shows that they do not disapprove of this situation.

The times are exceptional, and exceptional measures and men must be found to match them. Nevertheless we may hope that this is a precedent which will not be followed. Fellows must be able to feel free to criticize the presidents of the Royal Colleges in Council and Comitia, and by fearless advocacy of contrary opinions be able to take part in the needed evolution of these institutions. Those with great expectations for a prize may at times feel constrained to remain silent when it is a question of voicing an opinion thought to be unacceptable to a president who also holds the chairmanship of the Distinction Awards Committee. And, human nature being what it is, some may even be tempted to handle the base coin of adulation. A president's first duty is to promote the interests of his own College, and at times he may, not unnaturally, be unconsciously biased in favour of his own Fellows when it comes

to choosing for a prize one or two out of several candidates of almost equal merit. It is true that there is the safeguard of a strong committee and the most careful assessment of claims from the periphery. We have no doubt that the strictest fairness will be observed. Yet many people think that the presidents of the Royal Colleges should not be placed in an invidious position. It may be questioned whether they should serve even as members of the Distinction Awards Committee. It is not impossible that in future the decisions of this committee will be challenged, and it would seem to be important that the presidents of the Royal Colleges should remain free to criticize these decisions, and not be involved in them. The principle, we think, is important enough to deserve careful consideration.

CONGENITAL HEART DISEASE: A NEW APPROACH

The surgical treatment of congenital heart disease has been one of the most remarkable developments in recent years. In cyanotic heart disease, including Fallot's tetralogy, the Blalock-Taussig operation has proved of great value. The object is to provide an anastomosis between a systemic artery and a pulmonary vessel so that a proportion of the systemic "blue" blood can be shunted into the lung and there oxygenated. In the standard Blalock operation a subclavian artery is joined by an end-to-side anastomosis to the corresponding main pulmonary trunk, while in Potts's operation a side-to-side opening is constructed between the aorta and left pulmonary artery. In addition to these operations there have been successful attempts, including that described by Brock¹ in this *Journal* some months ago, to divide or excise a stenosed pulmonary valve and thereby to increase the blood flow from the heart into the lung.²

In the operation in which an anastomosis is to be performed it is essential that the vessels concerned should be large enough for the making of a satisfactory junction; unfortunately in a number of patients with cyanotic disease one or other pulmonary artery may be so small that such an operation becomes impracticable. In these cases the body itself makes an effort to improve pulmonary oxygenation by establishing numerous fine collateral channels in the region of the lung root, and the importance of these may be gauged by the fact that if they are divided and there is no adequate pulmonary artery death may result. Elsewhere in this issue Mr N. R. Barrett and Dr. Raymond Daley describe a method of treating the cases in which pulmonary arteries are too small for anastomosis by establishing new vascular channels along adhesions between the mediastinum and lung. The adhesions are made by stripping the parietal pleura from the upper part of the chest, then powdering the raw surface with asbestos dust, and re-expanding the lung. This can be done on both sides, and it seems probable that considerable revascularization over the raw area may occur. As an alternative method, omentum has been brought up from the abdomen and applied to lung, since it is known that vascular adhesions can also be established in this manner. Barrett and Daley have treated six patients by one or other of these methods, and they consider that the results were good in two cases and that there was clinical improvement in three. It is too early as yet to say whether the improvement will be permanent.

This form of operation may well be valuable in the treatment of patients in whom the more generally accepted

² Sellors, T. H., *Lancet*, 1948, 1, 938.

type of anastomotic operation is not possible, but at the same time modern methods of investigation must be employed in order to obtain before operation as much information as possible about the condition of the vessels. There are many variations of Fallot's tetralogy and other cyanotic conditions, and no hard-and-fast decision about the type of operation can be made until the chest is opened and the exact abnormality defined.

TOXOPLASMOSIS

Although the toxoplasma was known to be a parasite in certain animals as long ago as 1908,^{1,2} it was not until 1939 that toxoplasmosis was reported in a human patient, the case having been first diagnosed as encephalitozoic encephalomyelitis.³ Interest in the condition led to a careful review of some earlier case reports and in some cases to re-examination of necropsy material. As a result toxoplasma infection has been suggested as the cause of some previously obscure conditions; among these was a case of "coloboma of the macula lutea in a microphthalmic eye, with parasites in the retina" reported by Janku⁴ in Prague in 1923. Since 1939 several authors⁵⁻¹⁰ have reported cases of this infection, and recently Jacoby and Sagorin¹¹ have described the first case of congenital toxoplasmosis diagnosed in this country.

The first cases of toxoplasma infections to be recognized were in newborn babies, but later the condition was diagnosed in older children and adults. While in the latter the signs and symptoms may be diverse (pneumonia, fever, exanthema, gastro-enteritis), in children the usual clinical picture is that of meningo-encephalomyelitis, almost always accompanied by affections of the eye—the most frequent being bilateral chorioretinitis in the central area of the fundus. In a series of 15 cases identified by Wolf and his colleagues¹² as toxoplasmosis, 11 patients were examined ophthalmologically and of these 10 had chorioretinitis. Most lesions were in the healed state and took the form of atrophic pigmented areas resembling macular colobomata. In another report Wolf and his colleagues⁸ give the following criteria as typical of toxoplasmosis in infants: (1) onset very early in life; (2) symptoms of meningo-encephalomyelitis; (3) affections of the eye (especially chorioretinitis); and (4) cerebral calcification noticeable on radiographs of the skull. A certain diagnosis depends on the finding of the protozoon by biopsy or necropsy, either directly or after passage through animals. According to Binkhorst¹³ this had been accomplished in 18 cases up to 1945, 13 being congenital and five acquired infections. In the case reported by Jacoby and Sagorin the protozoon was not isolated, but neutralizing antibodies were found in the mother's serum.

While ocular disorders such as pupillary abnormality and paresis of ocular muscles have been described in cases of encephalitis, chorioretinitis has seldom been reported as a complication. Its discovery, therefore, in a case of encephalitis of unknown origin should at any rate bring the possibility of toxoplasmosis to mind, especially if cerebral calcification is present. The same would apply

if central chorioretinitis was found in a mentally defective child or in a child with Little's disease. The first report in the European literature of a case in which the diagnosis was confirmed *intra vitam* by the demonstration of toxoplasma-like parasites in animals inoculated with the cerebrospinal fluid came from Binkhorst in 1946.¹⁰ The patient was a 6-years-old girl who had been brought to hospital for treatment of a convergent squint. It was noticed that she stumbled when walking, had a copious flow of saliva, and a marked impediment of speech when she endeavoured to talk, which was seldom. Her stature was slight, and she had general motor weakness. Nothing abnormal was found in the lungs, the blood, or the cerebrospinal fluid. Microphthalmus and chorioretinitis were present, and radiographs of the skull in the bi-temporal and fronto-occipital planes showed multiple small and large opacities, with the density of calcium shadows, situated intracerebrally. Micro-organisms resembling toxoplasma were found in a cerebral granuloma in a guinea-pig after the intracerebral injection of cerebrospinal fluid from this case.

Infections of domestic animals in this country have not hitherto been reported, but Jacoby and Sagorin mention that a dog in Kent was recently found to have toxoplasmic encephalitis, the diagnosis being confirmed by identification of the protozoon. Toxoplasmosis in human beings may be more common than is thought, and it should be considered as a possible cause of visual disability in children in whom no direct interference with the light path is immediately noticeable.

BRITISH HOSPITALS ASSOCIATION

Voluntary hospitals having passed into history, it was inevitable, though none the less to be regretted, that the British Hospitals Association should follow them. The association, which is now being wound up, can look back upon a fine record of service extending over 65 years. Its end is in no sense due to any failure or shortcomings of its own. It is a political casualty, and the voluntary hospitals, whose interests the association so effectively represented, have now been taken over as a going concern continuing their service into the new era of regional administration.

The British Hospitals Association was formed to focus the views of hospitals under voluntary management, and with the help of a very large council, representative of hospitals all over the country, it brought them to the attention of Government Departments and public bodies generally. Its patron was the Duke of Gloucester, and its president for not far short of 30 years was the late Sir Arthur Stanley who had a lifelong enthusiasm for all hospital causes. The association also owed much to the wise guidance of its chairman, Sir Bernard Docker. It had 25 area committees, and a branch in Northern Ireland. The task it undertook was a difficult one. Voluntary hospitals were always highly individualistic institutions, proud of their traditions and jealous of their area of local or special appeal. It was no small matter to get them to combine for a common purpose, even for such a thing as the adoption of a uniform system of accountancy or statistics. In all the work connected with hospital financing and development of recent years, such as the growth of contributory and provident schemes, organized collections, the training of almoners, dietitians, and administrators, the association has exercised a useful influence. Under its auspices together with the Joint Council of the Order of St. John and the British Red Cross Society and other bodies, there was established a Central Bureau of Hospital Information

which has been responsible since about 1930 for the compilation of the *Hospitals Year Book*, incorporating *Burdett's Hospitals and Charities*, founded in 1889. This annual publication, alike as a directory, a financial review, and a statistical record, has made itself indispensable to all concerned with hospital administration, voluntary or municipal.

Early in the planning which led up to the National Health Service the British Hospitals Association put forward its own views. It recognized the value of a system of regional hospital councils, each council with its medical advisory committee, being set up as statutory bodies and charged with the duty of planning in detail for the hospital, consultant, and specialist service in their areas. It saw no difficulty in the continuance of two hospital systems side by side, with equal representation on the regional councils. The voluntary hospitals had never set out to establish a comprehensive service for the whole nation, and the association was fully aware of the enormous scope for local authority effort in the field of hospital provision. At the same time it urged that as the voluntary hospitals had accumulated a long tradition and experience, while local authority enterprise in this field was of comparatively recent origin, the voluntary hospitals might well form a touchstone against which the efficiency of the newer service could be judged. That was in 1944. Events have moved swiftly since then, and one of the unfortunate results is that, the voluntary hospitals having lost their voluntary status, the British Hospitals Association can no longer exercise its representative function on their behalf.

SAFETY IN CARS

In the aircraft industry physiologists and engineers have co-operated to design apparatus to eject pilots from the cockpits of high-speed aircraft and to reduce the effects of over-violent acceleration, whether in turning or pulling out of a dive. Another safety measure is the fitting of shock absorbers strong enough to take the strain of a bad landing even by a heavy aircraft. But, according to Woodward,¹ in automobile engineering "the only influence of aircraft design apparently so far adopted . . . is the erroneous one that the aerodynamic principles of a jet-propelled aircraft should be applied to a vehicle the speed of which should be limited to 55 miles per hour on the ground." Taken by itself there might appear to be an element of the dogmatic in the speed limit proposed. But in an inquiry conducted by the Safety Department of the American Automobile Association, out of 4,102 replies received four drivers favoured the introduction of governors limiting top speeds for every three which opposed such a device; and the highest speed favoured by the supporters of governors was 55 m.p.h. This, however, is only one factor and not perhaps the most important: for, though speed was found to be a contributory cause in two out of five fatal accidents, the proportion of accidents in which the speed had exceeded 50 m.p.h. was only one in five.

Woodward suggests that physiological and psychological principles should now be applied in automobile design in the same way as they have already been successfully applied in the case of aircraft. If all-round vision is important, then front supporting columns should be moved to the rear. If low windows lead to fractured elbows due to "side swipe"—a suggestion supported by radiographs—then windows should be higher. On the other hand, they should be wide enough to serve if necessary as emergency exits, and perhaps it is for this reason that Woodward

prefers a single door to two doors on each side. It might, however, be thought that two doors on each side would offer an improved chance of escape if one or more of the doors jammed as a result of an accident. To prevent front seats crashing forward in emergency stoppages and increasing the impact of knees or legs on dashboard would seem to be an elementary precaution. It would also be wise to include on speedometers an indication of the stopping distance appropriate to the speed of travel. It is not easy to provide a good view of the roadway from a "streamlined" car, and in the inquiry already referred to only one in six of American drivers voted for appearance as an important factor in body design. Some of us may feel impelled to cut a dash, in appearance as well as speed, when we take the road. If the American inquiry is anything to go by both qualities could be dispensed with without user protest provided that the more important quality of acceleration was retained. No doubt safer cars could be designed, and it would be interesting to see how far a campaign for a safe car, as opposed to one which looked and performed like a speed-track monster, could be commercially successful.

TREATMENT OF GONOCOCCAL VULVOVAGINITIS

The treatment of gonococcal vulvovaginitis before the introduction of the sulphonamides and penicillin was very unsatisfactory: it was always a prolonged process and often taxed the ingenuity of the most experienced practitioner. Relapse was all too common, and in some cases cure was delayed till the vaginal epithelium had changed its character from that of the infant to that of the adolescent. Even the sulphonamides were by no means always effective, and sulphonamide resistance was not unusual: whether this was due to resistant strains of bacteria or lack of reaction on the part of the host was often not clear. With the advent of penicillin the whole picture changed; a few injections of the drug in aqueous solution cured most patients, and even orally administered penicillin was often successful. Clarke and Eisenberg¹ treated 20 girls aged 2-10 years with a single intramuscular injection of 100,000 or 200,000 units of penicillin in oil-wax and obtained lasting cure in all but one case. The failure was in a girl most probably reinfected about four months after apparent cure, and she was finally cured by a second injection. Unless penicillin-resistant strains of gonococci develop—and up to the present there is no suggestion that they have—the outlook for controlling this previously intractable condition is bright. Moreover, much of the danger of cross-infection, so much feared in the past in residential nurseries and other institutions for young girls, will have gone, since infected children can now be rendered non-contagious in a matter of days or even hours.

The Moynihan Lecture will be given in the Riley-Smith Hall of the University Union in Leeds on Monday, April 25, at 3 p.m., by Professor G. Grey Turner, Emeritus Professor of Surgery in the University of London. His subject will be "Moynihan and the Training for Surgery."

Dr. N. Hamilton Fairley, F.R.C.P., F.R.S., will deliver the Croonian Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, May 3 and 5, at 5 p.m. His subject is "Malaria, with Special Reference to Recent Experimental Clinical and Chemotherapeutic Investigations."

A REGIONAL ORTHOPAEDIC AND ACCIDENT SERVICE

BY

G. R. GIRDLESTONE, D.M., F.R.C.S.

A few months ago this *Journal* (Oct. 23, 1948, p. 751) approved a short publication of mine on the organization of a Regional Orthopaedic and Accident Service within the National Health Service, and asked for further information. I am now trying to answer the questions; but as that article was written a year ago, when we knew very little about regional machinery, it is best to include a brief general review.

An Outline of the Service

A comprehensive orthopaedic and accident service should cover: (a) Acute diseases affecting the locomotor system, together with accidents of all kinds. These conditions require a 24-hour service in all the area hospitals of the region, best run in each such hospital under an orthopaedic and accident surgeon who lives in its vicinity. While the great majority of accidents involve the locomotor system, there may be damage to eye, brain, thorax, abdomen, etc.: thus the man in charge often requires the expert assistance of his colleagues in other branches of surgery. (b) The multiplicity of cases of congenital or acquired deformity, insidious disease, and so on, which may be termed the "cold" orthopaedics of the scattered clinics and the orthopaedic hospital.

There may be one or several orthopaedic hospitals in a region. In the Oxford region there are two—the Mansfield, at Northampton, and the Wingfield-Morris, at Oxford. My illustrations are taken from the latter, for which I have worked in a regional service for nearly 30 years.

In order to understand and appreciate the organization of a modern orthopaedic service the reader should bear in mind from the beginning two rather special considerations which are easily overlooked. The first is the necessity for widely scattered out-patient facilities for diagnosis and treatment. In "cold" orthopaedics children form a majority of the patients, and in this work *very early discovery, prompt effective treatment, and prolonged aftercare* are the three fundamental conditions of success. Now, a mother finds great difficulty in taking her child to a distant hospital; indeed, she will seldom do so unless the doctor's advice is reinforced by the child's obvious need. Thus the lack of a clinic within easy reach may be very harmful. If an early diagnosis is to be made the patient should be seen by an experienced specialist long before anything serious or painful is evident, and if cure is to be assured attendance must be kept up long after the success of treatment is apparent (and to the mother fully satisfying). For these reasons clinics within easy reach of every village in the region are regularly attended by the staff of the central orthopaedic hospital. In these neighbourly clinics early diagnosis is achieved much more often than would otherwise be possible, and the prolonged periodic follow-up which so many orthopaedic cases require is facilitated. This is no theoretical statement, but the outcome of ample experience.

Though many of these clinics are held in hospitals they are, taken together, the out-patient department of the central orthopaedic hospital, extended for the benefit of its distant patients. For three reasons it is essential that members of the senior surgical staff should visit the clinics: first, because very early diagnosis of major conditions is a matter demanding considerable experience and judgment; secondly, because the achievement of a full correction of these innumerable minor cases demands much co-operation from the parents, which can seldom be achieved without the authority and influence of a senior specialist; and, thirdly, because prolonged follow-up is far better carried out by a senior man who attends the clinic continuously year after year.

The second consideration concerns "cold" orthopaedics—a slow-moving complex field of work, in which sound judgment grows very slowly with experience and much failure and frustration, or fairly quickly and without failure and frustration by membership of a team of men, seniors and juniors, with all the opportunities of guidance and discussion

that this gives. It is characteristic of "cold" orthopaedics that a surgeon is often unable to distinguish between the ultimate success or failure of his treatment, or to assess the relative value of different methods of treatment, until years have passed. Furthermore, the great variety of disorders of the locomotor system afford a dangerously wide scope for invention: indeed, much ingenuity has been exercised in many centres for many years, with results varying from beneficial to disastrous. This is a potent reason for the frequent demonstration, examination, and free discussion of cases which will save the younger men from trying over again methods which appear excellent but have proved unsound. At the Wingfield the whole staff meets twice a week, spending about an hour and half on the examination (in one room) and discussion (in another) of five or six patients, new and old. This is the soundest possible source of learning.

A regional orthopaedic and accident service can be organized on the following pattern.

A. Central Orthopaedic Hospital

The whole organization is built round the central orthopaedic hospital, which in a regional centre is likely to form the clinical field of the medical school. It is probably better that it should be under the Regional Hospital Board than regarded as part of the teaching hospital, and that it should have its own individual board of management. There may more than one first-class orthopaedic hospital in a region, each the centre of its own regional organization.

These hospitals have a number of special characteristics: (a) wards designed for treatment in open air and sunshine; (b) theatres with every possible means of promoting asepsis and, preferably, a Plenum system of filtered-air ventilation; (c) plaster-rooms with much special equipment; (d) first-class radiographic and photographic departments; (e) physiotherapy with treatment baths for anterior poliomyelitis and much other special equipment, and staffed by experts; (f) occupational therapy; (g) school teachers for the education of children school age (2-16) grouped suitably by ages in wards; (h) workshops equipped and staffed for the quick and exact manufacture and fitting of splints, and research into new designs and materials.

Hospital Records.—That clinical records should be full and accurate is of particular importance in an orthopaedic hospital because many of its patients are under treatment from time to time over many years, and without explicit and reliable records the progress, whether improvement or deterioration, may be impossible to assess with any accuracy. Here the visual records of photographs "before and after" and of sn individual "before and after" loops of cinematograph film are of extraordinary value; for by these demonstrative and realistic means the surgeon is made fully aware of the effect good or bad, of his treatment.

Research.—The opportunities for clinical research are many; the need is great—perhaps especially for more exact knowledge on the relative value of different methods of treatment, based on written, radiographic, photographic, and cinephoto records before and after. Each orthopaedic hospital ought to keep such records and make accurate assessment of its end-results in complete series of cases. It would find the material which some for its own consumption; and it could thus contribute to the general knowledge of orthopaedics. It is desirable that members of the surgical staff should be given an opportunity of taking part in animal research in university laboratories.

Library.—There should be a good medical library, with facilities for reading, writing, and dictation for all members of the staff.

Pathology.—For regional work the clinical pathology should be carried out in laboratories under the supervision of the senior clinical pathologist of the teaching hospital. This seems preferable to a completely independent system of laboratories.

B. Regional Staff—Central Orthopaedic Hospital

Director of Orthopaedic Services.—The clinical administration of the Regional Orthopaedic Service within the central orthopaedic hospital and throughout the region is best entrusted to one of the surgeons, who will of course work in the clinic

touch with his colleagues as a member of the Staff Committee. Much of his work is clinical administration; some of it is clerical, to co-ordinate and facilitate the working of the organization. Most of his decisions are made after full discussion with the Staff Committee; particularly will this be so when something has to be done to improve an unsatisfactory service. If he should turn out to be too much of a "director" he can be replaced. The post should not itself carry any extra emolument; so that if a change of directorship should be desirable it may be made without financial disturbance.

Regional Consultants.—Several of the senior surgeons of the central orthopaedic hospital should be recognized as regional consultants and be responsible for the orthopaedic departments in the area hospitals. Each of these men will visit one or more such hospitals every week. Here he will have the assistance of the local orthopaedic and accident surgeon, and they should work intimately together in the wards, theatre, and out-patient department.

Specialist Surgeons.—A number of surgeons who have not yet reached regional consultant rank complete the surgical staff of the central orthopaedic hospital, which should provide about one surgeon to every 50 beds. The work of the staff covers the intramural work of the central orthopaedic hospital, the orthopaedic and accident departments of the central and area general hospitals, and the outlying clinics.

Professor of Orthopaedic Surgery.—Where the regional hospital is closely associated with a teaching hospital its staff may include a professor of orthopaedic surgery, who, with his first assistant, can be given charge of one of the units of the hospital. He thus plays his part in the regional work of the hospital. He is responsible to the university for the organization and carrying out of all academic activities throughout the hospital. In an article so general as this it is hardly possible to specify the relations between the regional director, with his widespread administrative and co-ordinating duties, and the professor, with his academic interests. Much will depend on individual circumstances. Their functions should always be mutually helpful.

The establishment of resident staff is as follows. At the central orthopaedic hospital, with, say, five surgical units: one resident of senior registrar status and five house-surgeons of junior registrar status. At each of the area hospitals with accident and orthopaedic departments the services of a man of senior registrar status and a house-surgeon are required.

C. Area Hospitals

In the area hospitals—i.e., the principal general hospitals of the region—there are (1) the orthopaedic department, mainly for out-patient service, but with some beds for short-stay cases; and (2) the accident service.

The staffing of these outlying units is of particular concern. The orthopaedic and accident work should be closely co-ordinated. It is essential that the surgeon in charge of the service should be a member of the regional orthopaedic team. The best arrangement is that the visiting regional orthopaedic consultant who is responsible for the orthopaedic department of the area hospital should also be consultant to its accident service and be prepared to see difficult cases and discuss problems with the accident surgeon, and that the latter, in turn, should work in the orthopaedic department as assistant surgeon (to use the old term), and be on the staff of the central orthopaedic hospital. For these outlying posts it is possible to pick from a strong field of candidates a man with sound experience of the accident side of orthopaedics, with a Fellowship, and with a background of sound surgical training. But for the most part, when appointed, he has not had very much experience of "cold" orthopaedics.

Nevertheless these men are from the first active and valuable members of the orthopaedic staff of the region, not only taking care of orthopaedic emergencies (their primary service), but also helping the visiting consultant to cope with the flood of "cold" orthopaedics which comes to an area hospital. Their value in this field will increase as they accept the opportunities of absorbing orthopaedics from their association with the central orthopaedic hospital. Whenever possible, they take part in the clinical conferences at that hospital as a member

of its staff and on sessional duty. Even if the pressure of work makes some of these visits to the centre impracticable they have the advantage of close association with an orthopaedic specialist who has been working in that intensive school for years. Thus, for example, in the southern part of the Oxford region there is in view a staff of five whole-time surgeons living at the centre, with four men working in and living near the area hospitals.

There is a tendency to speak of major and minor orthopaedic cases and to set up a distinction between them in regard to their need of specialist skill—let us say between the lesions of the spine and the larger joints and those of the hand or foot. This is a mistake. The smaller tasks are often the more delicate and intricate, requiring as much judgment and more exact technique—and what happens to his hand or foot is of major, not minor, importance to the patient. But many of these short-stay cases make no special demands on hospital design and equipment, and therefore need not be admitted to the central orthopaedic hospital.

D. Outlying Clinics

A certain number of *ad hoc* orthopaedic clinics in the smaller towns have been found necessary, in addition to the orthopaedic out-patient clinics of the general hospital, in order to bring the means of specialist diagnosis, treatment, and after-care within the easy reach of patients, particularly children, in every part of the region.

E. Proportion of Beds to Population

It is probable, judging from our own experience at the Wingfield, that about 300 beds per million population are sufficient, provided that the beds in the central orthopaedic hospital are supplemented by provision of a total of 40 or 50 beds for short cases in the associated general hospitals. Orthopaedic hospitals do, however, differ considerably in regard to the type of cases they admit. In the Wingfield we have always had a considerable proportion of active orthopaedics—i.e., acute inflammation or injury of any part of the locomotor system—a good many cases of difficult fractures, non-unions, mal-unions, and so on, and internal derangement of joints. On the other hand, by a very closely knit system of orthopaedic clinics we are able to allow patients to leave hospital very much earlier than is otherwise possible. Almost all our patients go home a few days after first getting out of bed.

F. Aftercare Sisters—Orthopaedic Physiotherapists

These are highly trained girls who have obtained a certificate in orthopaedic nursing, are members of the Chartered Society of Physiotherapy, and have had a postgraduate training in the great variety of plaster and splint work used in orthopaedics. This triple training makes them invaluable in out-patient orthopaedic work of every kind, as well as in the plaster-room of the central and area hospitals. Their responsibilities and duties have hitherto been primarily those of working for the orthopaedic surgeons in the plaster-rooms of the central orthopaedic hospital, in the out-patient departments of the area hospitals, and in the outlying clinics. But they have carried in addition the responsibility of attending the outlying clinics weekly between the surgeon's periodic visits and carrying on treatment by remedial exercises, plaster work, and the supervision of splintage. Their remedial exercise work is largely class-work, made effective by their capacity to impress upon the mothers of the children the importance of keeping up these exercises and maintaining good posture during the intervening period. This is simple and economical, and can be a most effective way of getting rid of postural defects, with far less interference with school-time than is necessitated by the regular attendance of children at the hospital or clinic for daily remedial exercises. It is noteworthy that, at a census taken in 1927, of 540 children under treatment at clinics in Berks, Bucks and Oxon, 509 were attending school.

The number of children attending the clinics is, of course, only a small proportion, probably a very small fraction, of the number who need remedial exercises. Here we see the immense advantage of close liaison between the orthopaedic personnel and the School Medical Service, with organizers of remedial exercises associated with that Service. This association is

valuable both in regard to the supervision of the right sort of exercises in schools by the School Service and in promoting the recognition of those types of deformity which call for the attendance of the child at an orthopaedic clinic for diagnosis and treatment.

Our staff numbers five fully trained members and one undergoing postgraduate training. They live in the neighbourhood of the central orthopaedic hospital. Their time is divided in about equal proportions between work in the central orthopaedic hospital and the outside hospitals and clinics.

Three Important Questions

Three questions remain to be answered—those of cases of acute anterior poliomyelitis, combined pulmonary and skeletal tuberculosis, and workshops.

Acute Anterior Poliomyelitis.—In general, cases of acute anterior poliomyelitis can be admitted and isolated in the central orthopaedic hospital as soon as they can safely be moved. It is probable that more can be done to minimize the severity of paralysis during the first three weeks than at any subsequent stage. In a time of epidemic, however, there is likely to be too great a rush of cases for this immediate admission and isolation to be practicable; therefore a sufficient number of beds in an isolation hospital within easy reach of the central orthopaedic hospital should be allocated to meet this need, and the patients placed under the joint care of the isolation medical and nursing staff on the one hand and the orthopaedic surgeons and aftercare sisters on the other. Where such ready co-operation can be promoted the effect is admirable. As the patients pass out of quarantine they can be admitted to the orthopaedic hospital.

Combined Pulmonary and Skeletal Tuberculosis.—Pulmonary tuberculosis is best treated in a sanatorium, and skeletal tuberculosis is best treated in an orthopaedic hospital where the surgeon and his resident staff devote their whole time to the study and care of the locomotor system, and where constant practice makes the nurses capable of ensuring the comfortable, effective, and long-continued immobilization of a hip or a spine on a frame or in plaster. It is recommended that a special unit should be developed for this work in every region, as convenient as possible for the physicians and surgeons concerned. Experienced nurses, prepared for long-term service, are necessary, for only thus can their patients be given comfort and confidence through a lengthy period of confinement which is always difficult and can be very distressing.

Workshops.—I can best answer this question by saying that our Wingfield workshops have been fulfilling the needs of the Wingfield Hospital and its clinics, together with some work, mainly but not exclusively orthopaedic, for the Radcliffe Infirmary, Oxford, the Royal Berkshire Hospital, Reading, the Royal Buckinghamshire Hospital, Aylesbury, the R.A.F. Hospital at Halton, and the Ministry of Pensions Hospital at Stoke Mandeville. It is probable that this workshop staff and equipment could serve a regional orthopaedic and accident service for a population of at least a million. Our staff and space consist of:

Superintendent ..	Office, 68 sq. ft. (6.3 sq. m.)
Clerks (2) ..	General office, 220 sq. ft. (20.4 sq. m.)
Boot repair dept. (9) ..	680 sq. ft. (63 sq. m.)
Machine shop (6) ..	(including one blacksmith) machine shop, 864 sq. ft. (80 sq. m.); forge, 130 sq. ft. (12 sq. m.); welding, 81 sq. ft. (7.5 sq. m.)
Carpenter's shop (1) ..	490 sq. ft. (45.5 sq. m.)
Saddlers (3) ..	432 sq. ft. (40 sq. m.)
Stores ..	306 sq. ft. (28.4 sq. m.)
Fitting-room ..	180 sq. ft. (16.7 sq. m.)
Waiting-room ..	54 sq. ft. (5 sq. m.)
Dispatch-room ..	80 sq. ft. (7.4 sq. m.)

Conclusions

A Regional Orthopaedic and Accident Service can render a high standard of service if the personnel is first-rate and works as a team in a well-planned and complete organization. The orthopaedic and accident services should be closely articulated in those parts of the region where they are not fused. In the area hospitals a local orthopaedic and accident surgeon is

in immediate charge of the work as a member of the regional team. The orthopaedic service is directed from the central orthopaedic hospital, with an out-patient department in every hospital and in sufficient additional clinics to bring a consultant frequently within reasonable reach of every village in the region. This arrangement and other extramural organization are necessary to bring about early diagnosis, regular attendance, and thorough follow-up. The efficiency of treatment depends on the ability, spirit, and character of the members of the team, for in truth much of the clinic work will prove tedious to the staff, and largely ineffective to the patient, unless it is tackled with obvious and infectious interest. Though organization can facilitate their attendance, patients will keep coming only if they understand what is being done for them and why it must go on so long.

Orthopaedic work must be very good or it is marred by frequent failure and much disappointment. It demands a great deal of skill and effort from all concerned, and particularly is this true of "cold" orthopaedics, for in this field there is often a strong tendency towards recurrence of deformity, with as much harm as help from *vis medicatrix naturae*.

My work for the E.M.S. in two regions during the war made me acutely aware of the needlessness suffering that was being endured and the disablement that was being promoted in reputable hospitals as a result of members of their surgical staff treating fractures in an atmosphere of isolation and seclusion. For example, I found a young soldier who had suffered a compound fracture of the femur a few days before, in great pain and distress. His lower limb was tightly bandaged to a long Liston splint, the upper part of which was completely free in the bed and some distance from the trunk. The fracture was uncontrolled and in obvious varus deformity, and I was told that the splint was detached daily for dressings.

Regional Hospital Boards have indeed grave responsibility—and great opportunity. They can put an end to a long epoch of isolation and seclusion in which the work of individual surgeons all over the country has been good, bad, or indifferent. Isolation bred incompetence, seclusion hid it, and no one could do anything about it.

Each Board must aim at a sound organization, staffed by a team of men who share their advance in knowledge and clinical experience, a team who will thus come to be distinguished by the diffusion of a high standard of skill and a spirit of whole-hearted service. In order to achieve such a team there must be some devolution of authority step by step from the Director of Orthopaedic Services right through his senior and junior colleagues, the resident staff, and all the personnel of ancillary departments and clinics. Since the team is animated by a common purpose this authority can be exercised almost entirely by the guidance and personal influence of the senior men. When, however, a man continues to prove himself unable to render first-class service his appointment must be terminated by the Board.

The regional organization on which this article is based has been tried over many years, and has earned the approval of local authorities, voluntary hospitals, and all concerned. How far it can be applied to other specialties I do not know—probably only in some of its features. It seems likely that a considerable number of autohousous areas will be required for medicine, for surgery, and for gynaecology. No doubt, too, a pattern which suits the country as a whole will be modified for the service of industrial areas with great density of population.

In many regions local associations for the care of cripples will be found; these are voluntary bodies capable of giving most valuable help to the secretaries, almoners, and surgeons of orthopaedic hospitals.

The American people are contributing funds to finance a campaign against heart disease. The American Heart Association is seeking five million dollars to carry out research, to spread information about the disease, and to provide community services for its victims. President Truman has urged that the utmost support of governmental and voluntary organizations be given, and said recently, "Combating the nation's leading cause of death has become our most serious national health problem."

TRAINING OF NURSES

NURSES' BILL

The Nurses' Bill, which is sponsored by the Minister of Health, was given a first reading in the House of Lords on April 12. The Bill is intended to improve the training of nurses, and its provisions follow closely some of the recommendations of the report of the Working Party.¹ This report² criticized the present constitution of the General Nursing Council which was first set up³ under the Nurses Registration Act of 1919. It urged, for example, that elections to the Nursing Council should be by hospital regions. The report also proposed the reorganization of the present methods of training nurses. These proposals, which we commented on in a leading article,⁴ have now been put before Parliament in the form of this Bill, of which the full title is "An Act to reconstitute the General Nursing Council for England and Wales and otherwise to amend the Nurses Acts, 1919 to 1945, and to make further provision with respect to the training of nurses for the sick."

Reconstitution of General Nursing Council

The proposed new Council will consist of 34 members, of whom 17 are to be elected by nurses, 12 appointed by the Minister of Health, three by the Minister of Education, and two by the Privy Council. Of the elected members, one will be drawn from each of fourteen areas designated by the Minister. There will also be special representation for mental nurses, sick children's nurses (by election), public health nurses, sister tutors, ward sisters, and male nurses (by appointment).

A Mental Nurses Committee of the General Nursing Council will consist of six members of the Council (including two mental nurse members), two elected mental nurses, and four persons appointed by the Minister—a matron, a mental nurse tutor, "a doctor teaching psychiatry," and a chief male nurse. Matters mainly concerning mental nurses other than questions of registration or removal from the Register will be referred to this committee.

If this Bill is enacted the General Nursing Council will not be able to refuse approval, or to withdraw approval, from a training institution without giving the managing body written notice and an opportunity to be heard. Appeals against such refusal or the withdrawal of approval will be heard by a person nominated by the Lord Chancellor, instead of being made to the Minister of Health. The General Nursing Council will be empowered to admit to the Register nurses trained anywhere abroad to a standard considered by the Council to be satisfactory, or, if below that standard, after such further training as the Council may direct. This proposal will replace the provisions of the 1919 Act, which restricted such admission to the Register to those Dominions that granted reciprocal treatment to British nurses.

Male nurses, who are at present only admitted to a special supplementary part of the Register, will in future be admitted to the general part of the Register. A minor but important change is that the General Nursing Council will be empowered to charge nurses already registered or enrolled fees for life registration or enrolment. These fees will take the place of the present annual retention fees. The General Nursing Council will no longer be under an obligation to publish the Register but will publish periodical lists of admissions and removals.

Proposals for Training

The Minister will be given power under this Bill to constitute by order standing nurse-training committees for each of the fourteen hospital areas in England and Wales. The members of these committees will be representative of regional hospital boards, boards of governors, the General Nursing Council, the Central Midwives Board, local health authorities, local education authorities, and universities. Among the duties of these committees will be the promotion of improvements in nurse-training and research into methods of training; advice and assistance to training institutions in preparing and carrying out

training schemes; and advice and assistance to the General Nursing Council on the approval of training institutions.

These regional nurse-training committees, which are very much as envisaged by the Working Party, will also allocate among the training institutions the money provided by the Exchequer through the General Nursing Council for training. By this means the finance of nurse-training will so far as practicable be independent of the finance of hospital administration. Experimental schemes of training which are not in accordance with the rules in force at the time may be adopted by these committees subject to the approval of the General Nursing Council.

One of the last clauses in the Bill empowers the Council to pay to its members and to members of the Assistant Nurses Committee sums in respect of the loss of remunerative time as well as travelling and subsistence expenses. The Bill, which is a short one of 19 clauses and three schedules, will have the effect of repealing many of the provisions of the Nurses Registration Act, 1919, and the Nurses Act, 1943.

Preparations and Appliances

VAGINAL DILATORS

W. McKIM H. McCULLAGH, F.R.C.S., F.R.C.O.G., senior obstetric surgeon, City of London Maternity Hospital, writes: The standard glass vaginal dilators are readily broken and occasionally an undiscovered crack causes their disintegration in the vagina, with difficulty in removing the fragments. In addition, the glass dilators have no handles, and, as half of those patients requiring their use have psychological inhibitions in regard to the entry of anything into their vagina, it is

important that their phobias be considered and that the instruments used be as little fearsome as possible. Handles inserted at right angles to the penis replica assist in instructing the patient in the location and direction of her vaginal passage, which is an important factor in curing dyspareunia and assisting coitus. The upper and anterior surface of the dilator is grooved, to lessen pressure on the urethra.

One is surprised at finding not a few long-married patients each year still *virgines intactae* and others ignorant of the fact that a happy marriage necessitates painless complete physical union. I find these new forms of dilators here illustrated of great assistance in treating such cases, and especially so in vaginismus cases, where even after dilatation of the vagina by operation the introduction of a small dilator causes vaginal spasm. Personal attention by the surgeon is psychologically necessary, and these safe dilators give extra confidence and extra mechanical knowledge to the patient when introduced day by day in order of size, after operation, till a sufficiently large one is employed.

The metal dilators are hollow, and are supplied in nests by Allen & Hanburys, of Wigmore Street, W.1, and the Coldlite sets are supplied by Vann Bros., of Weymouth Street, W.1.

During the first quarter of this year 276 children were admitted to Dr. Barnardo's Homes. The number of children rescued from destitution by these Homes in March was 114.

Correspondence

Diabetic Coma

SIR,—I have read with great interest Dr. J. G. H. Sheppard's account (April 2, p. 576) of a case of diabetic coma treated with 56,000 units of insulin, and congratulate him on both his courage and its reward. In view, however, of the great potential dangers associated with the use of active insulin in such heroic dosage I would like to ask whether a control test for potency was carried out on the insulin used in this case.

It is important to remember that the giving of 56,000 units of insulin does not prove that this dose was necessary or, in view of the severe delayed hypoglycaemic reactions described, even desirable. It seems probable that in the very severe type of case described by Dr. Sheppard a large proportion of the insulin given in the resistant phase is destroyed before it has time to act, and I know of no convincing evidence that the amount of insulin utilized can be increased by increasing the dose above a certain optimum level. Experience would suggest that this level is far below the dose given by Dr. Sheppard. No mention is made of the volume of fluid administered intravenously, and the persistence of a very high pulse rate suggests the possibility that more rapid clinical improvement might have resulted from more intensive treatment of the dehydration.

I find it difficult to believe that the sudden collapse was due to the accidental substitution of 5% glucose for normal saline in the drip, especially in view of the controlled observations on the mode of action in diabetic coma of saline and glucose respectively published by Drs. J. Lee, D. Naidoo, and J. A. Torrens in the same issue (p. 565). Incidentally, in the article referred to, the authors correctly include the name of Dr. R. D. Lawrence among those who "administer glucose as a beneficial procedure" in diabetic coma, but I would like to point out that in the department of which he is the director it has been the custom for the past ten years to give normal saline for the first three hours of treatment of cases in diabetic coma.—I am, etc.,

London, S.E.5.

WILFRID OAKLEY.

SIR,—Professor H. P. Himsworth (April 9, p. 632) considers our glucose-treated and saline-treated cases (April 2, p. 565) not comparable because he feels that the age levels, the alkali reserve, and the blood-pressure readings can be interpreted differently.

First, with regard to the age, the mean for group A is 35.9 (standard error of mean ± 5.15 , standard deviation 16.3) and for group B 33.3 (S.E. of M ± 3.74 , S.D. 15.9). These are comparable. It is true that mortality rises with age, but there can be no justification for making a special choice of 50 years, which taken by itself can give little information about the duration and severity of the diabetic process and the degree of its detrimental effect on the cardiovascular-renal and nervous systems. Had Professor Himsworth chosen 40 as his necessarily arbitrary critical age he would have been faced with 9 cases in the saline series and only 3 in the glucose series, producing the very opposite impression. Nevertheless, the over-50's in the saline cases did not die.

Secondly, the errors inherent in the estimation of the alkali reserve at such low figures make the alleged difference of 2.2 vol. CO₂ per 100 ml. between 9.8 vol. and 12 vol. meaningless. But this difference is only the result of Professor Himsworth's arithmetic. In fact, the actual averages for the fatal cases in each group are 9.8 vol. and 9.5 vol.—very similar figures. Joslin (*Diabetes Mellitus*, 1940, 7th ed., London, p. 388) says that "among unconscious patients the percentage of deaths was essentially the same in the group with CO₂ values above 10 vol. as with the group with low values." No single factor is all important, and even in a combination of factors each will assume a different relative importance. We have used Collen's index, which is not an absolute standard, but as it is equally applied to both series it is governed by no more logic than a yard-stick.

Thirdly, the average systolic and diastolic blood pressures in each group are comparable. Any special selection on the

basis of an arbitrary figure can be of little value. A consideration of the diastolic pressures might equally be taken to indicate that the fatal saline cases were more serious than the fatal glucose cases.

We do not wish to claim that our contention is "mathematically significant," because for this purpose we should have required almost twice the number of cases. Over fifty cases treated under strictly similar conditions would have been impossible to collect in a period which included the final months of the war, with its attendant nursing difficulties, and which saw the introduction of penicillin. Our poorly documented wartime cases which were treated with glucose but were not included in the series because of the special difficulties encountered in their management bear out the mortality figures given for the group A cases. Group B cases now total 20 with 2 deaths.

We agree emphatically with Professor Himsworth that glucose is a potent weapon for the correction of disordered carbohydrate metabolism, that the depleted electrolytes should be supplied, and that the rapid fall in plasma potassium and phosphorus may lead to serious symptoms.

We wish to point out that although it was not possible to provide a sufficient number of cases for strict mathematical proof our cases provided evidence that the administration of glucose to seriously dehydrated cases of diabetic coma in the early stages of treatment increases the water output, interferes with rehydration, worsens the state of circulatory collapse, and in some cases may indeed precipitate death.—We are, etc.,

J. LEE.
D. NAIDOO.
J. A. TORRENS.

Isleworth, Middlesex.

SIR,—Drs. J. Lee, D. Naidoo, and J. A. Torrens (April 2, p. 565) have endeavoured to demonstrate that the administration of glucose to serious cases of diabetic coma in the early stages of treatment "increases the mortality significantly." For this purpose they took 28 comparable cases and found that, using glucose, 10 cases suffered a 40% mortality, whilst 18 cases, using saline, suffered an 11% mortality. They have then "proved" their point.

However, if we examine their results statistically it can be shown that these two series of cases have a standard error of 16.2%. The difference between the percentage mortalities (40%–11% = 29%) is less than twice the standard error, and it is generally accepted that this difference might easily have arisen by chance and is not significant. The series of cases quoted is much too small to justify the authors' claims.—I am, etc.,

London, W.9.

C. A. ROYDE.

SIR,—I quite agree with Drs. J. Lee, D. Naidoo, and J. A. Torrens (April 2, p. 565) in the conclusions of their valuable contribution to the question whether or not to use glucose as a preliminary measure in treating diabetic coma. Although the comparison is somewhat difficult because of a slight difference in the age of both groups, this difference is more marked by the lower figures of the alkali reserve in group A, the glucose-treated cases. The common feature in the fatal cases of both groups is the very low alkali reserve (with one exception 10 or under 10 vol. CO₂ per 100 ml.). Though the Collen index is equal in both groups, this index takes no account of the depletion of the CO₂ reserve—a most important factor in assessing the severity of the case and the chances of recovery. If the CO₂ reserve is very low and does not improve markedly within the first 4–8 hours, the chance of recovery is poor. It is, therefore, more important to give an alkali intravenously as a preliminary measure. The absorption by the stomach is often very much impaired in diabetic coma, and any solutions given are either vomited or found many hours later in a greatly dilated stomach, as proved at necropsy.

The importance of the alkali reserve in the treatment of diabetic coma has been pointed out by Professor H. P. Himsworth (April 9, p. 632), who refers to the recent investigations by Butler and his colleagues.—I am, etc.,

Wembley, Middlesex.

S. P. BARTFELD.

The Intervertebral Disk

SIR,—The *Journal* of Feb. 12 has three contributions that illustrate the increasing importance of the intervertebral disk.

(1) When a stooping man begins to extend his spine, says Sir H. E. Griffiths (p. 255), the posterior margin of the disk is compressed between the posterior margins of the vertebral bodies.

Comment.—This could happen only if the vertebral body pivoted on the disk, as the tibia pivots on the talus. The vertebral bodies, in fact, move apart during extension of the joints, which are situated three centimetres behind the posterior margins of the bodies; pressure on the disk is therefore reduced.

(2) Perforation of the annulus fibrosus by a spinal needle is followed by seepage of the nucleus pulposus through the hole (Dr. C. Langton Hewer, p. 283).

(3) When pain in the leg follows septic infection of the lumbar canal we are required to believe ("Any Questions?" p. 292) that the disk must have been injured during a supposedly ill-performed lumbar puncture.

Comment.—The annulus fibrosus must disobey the rules of healing that are observed by all other tissues. Puncture even of an artery—whose contents are fluid and under high pressure—does not lead to escape of its contents. The nucleus, too, must be unlike all other tissues: it is fluid enough to seep out through a tiny puncture in a ligament and at the same time solid enough to interrupt nerve roots by pressure.

In order to make possible behaviour that is without parallel in biology, the quality of "turgor"—self-expansibility—is often attributed to the nucleus. But "to ascribe turgor or power of expansion to the nucleus is to invoke some property quite unknown in the physical world and takes medicine back to the obscurantism of the Middle Ages. . . . If the volume of a fluid increases, something must have been added to it from without; if it decreases, part of its substance must have been removed."¹

The disk is nothing but a resilient bit of fibrocartilage, more cartilaginous in its centre and more fibrous at its margins. It cushions sudden or intermittent pressure by flattening and it is restored to its previous shape when the compressing force is removed. Its resilience is shown by the rarity of disk lesions in compression fractures of vertebral bodies. It is rarely seen as a whole because of its inaccessibility, and—on the principle *omne ignotum pro magnifico*—fairy tales have been invented about it that can be disproved only by the expenditure of much labour. We are a credulous profession and often prefer the incomprehensible to the simple explanation.

In other parts of the body pain that appears during muscular effort is due to strain of muscles or ligaments. In many cases of back strain the same cause can be demonstrated by local analgesia. Yet the recent fashion demands that we invoke a complicated mechanism whose reality cannot be proved, that makes of the vertebrochondral relationship a ball-and-socket joint, and that takes away from the pedicles and articular processes their historic function of weight-bearing.

We take advantage of this weight-bearing function when we allow a patient with a crush fracture to walk about with his spine in extension. Narrowing of an intervertebral space is always secondary to failure of the weight-bearing structures through decalcification, with sagging and sometimes the appearance of linear stress fractures.² The disk, which is not constructed to bear continuous pressure, accommodates itself by flattening. Narrowing of the space, therefore, is not the cause of the pain but a later effect of the decalcifying process. —I am, etc.,

Melbourne, Australia.

Bronchography and Surface Analgesia

SIR,—Mr. R. C. Brock (March 12, p. 454) strongly condemns bronchography by direct tracheal puncture. He favours the use of an indirect method in which the iodized oil is trickled into the glottis from the nose or pharynx, and he argues that direct puncture is unnecessarily dangerous, more complicated, and gives no better results than the indirect method. Never-

theless, after trying both techniques, we are convinced that tracheal puncture is a safe procedure and that it has definite advantages over the indirect methods.

In the past our experience on the resident staff of the Brompton Hospital covered a period of thirteen years, during which time we saw almost all the bronchograms performed there. These amounted to over 10,000, the large majority of which were done by direct puncture. The only serious complications were four cases of cellulitis of the neck; all these occurred in patients with large amounts of heavily infected sputum, which we now regard as a contraindication to the use of this method. All recovered satisfactorily, although they occurred before the days of chemotherapy.

Direct puncture requires a little more apparatus than the indirect method, but in our opinion the superior results more than compensate for this. The method itself is easy to master: with proper tuition, and its speed commends it to both doctor and patient. Our criterion of a good bronchogram is that every segmental branch of the appropriate bronchial tree shall be outlined. There is always an element of luck in bronchography, and it is impossible to guarantee one hundred per cent success with any method. Nevertheless, after long experience we are convinced that tracheal puncture produces a higher percentage of good bronchograms, particularly of the upper lobes, than the indirect translottic methods. The direct puncture technique has the great advantage that the patient can be placed in the appropriate position for outlining each lobe before the oil is introduced.

Properly performed, tracheal puncture is painless, and patients who have had experience of both methods often prefer it because it is quicker. We have done bronchograms by direct puncture under local anaesthesia on intelligent children as young as six years without causing them any distress.

We agree with Mr. Brock that the cricothyroid membrane is best avoided; the needle should be inserted into the trachea just below the cricoid cartilage. A few minims of procaine are sufficient to anaesthetize the skin, and we agree that many patients will tolerate the introduction of the iodized oil without further anaesthesia. But a few will not, and it is not possible to pick these out beforehand. One good cough can ruin a bronchogram, and therefore we inject 0.5 to 1 ml. of 2% "butyn" into the lumen of the trachea as a routine measure. Tracheal puncture should not be used if the patient has large quantities of fetid sputum, and in such a case an indirect translottic method is preferable.—We are, etc.,

G. S. TODD,
King Edward VII Sanatorium, Midhurst.

Brompton Hospital Sanatorium, Fimley.

Penicillin-resistant Staphylococci

SIR,—Drs. A. Voureka and W. Howard Hughes (March 5, p. 395) state that they identified 315 distinct strains of staphylococci obtained from 241 patients on the basis of colonial appearance, haemolysis, and coagulase production. I find this difficult to believe, and thought that such nice distinction could only be obtained by phage-typing. I should be glad if anyone could confirm that such results are possible. Staphylococci are of major importance in Saskatchewan and constitute an important part of the work in bacteriology in Regina. Since phage-typing is not readily available it is important to know if such distinction in typing can be achieved by the naked eye. For myself, I think not.—I am, etc.,

Regina, Saskatchewan.

N. G. B. McLEITCH.

Adoption

SIR,—The Adoption Bill is evidently intended both to facilitate desirable adoptions and to safeguard children from being placed out unsuitably; it may be hoped that in its ultimate form, after the incorporation of desirable amendments, it will do both more effectively.

It starts with the statement (Section 1 (1)) that a child may be adopted by his mother with or without her husband, or by his natural father with or without his wife. Adoptions of a child by his mother and her husband are already frequent, and no doubt the great majority of legal adoptions by a child's own mother, which were stated in the debate in the House

to be a third of the whole number, are by her and her husband together. Those who come professionally into contact with mothers in difficult circumstances can sometimes help them to take heart about the future by emphasizing to them and their relatives the truth that a man who marries a woman who already has a child often wishes to bring up her child as though he were his own, and can with her legally adopt the child and so give him his mother's new married name. It is not true that a mother who rises to her responsibility for her own child is less likely to marry happily in the future than if she gives her child away, on the contrary, a happy marriage is much more likely to be founded on candour and responsibility accepted than on secrecy and responsibility evaded.

Adoptions by a mother and her husband also include some where a married woman has given birth since her marriage to a child by another man. Such a child already has a claim to his mother's married surname even without adoption by her husband, and his birth certificate, if the new short form is used (available since 1935 in Scotland and 1947 in England) need not reveal any irregularity. Therefore a husband who is prepared to accept his wife's child out of mercy towards him or love of his mother may not feel any necessity to adopt him legally, but it is perfectly competent for him to do so with his wife, and the point of Section 1 (1) is not to make this legal but to call attention to the fact that it is legal already. Knowledge that it is possible may come as a great relief to a husband who wishes to express in action his reconciliation with his wife and good will to her child.

This Bill will be valuable if it stimulates adoption by a child's own kindred, but no legislation is needed to stimulate offers of adoption by strangers. Would-be adopters who appear suitable at first sight already exceed in number the suitable children available. There is accordingly never any need to jump at the first offer of adoption that presents itself, and Section 5 of the Bill is apparently designed to lessen the risk of over-hasty or unsuitable adoptions.

Negotiations for the adoption of a child into the family of strangers should not be entered into before he is born or without the sponsorship of a registered adoption society or local authority, for the following reasons:

1 No final judgment that a child is suitable for adoption can be made until he is born and has been carefully tested and observed. The placing of children who prove physically or mentally unsuitable causes very great disappointment and difficulty.

2 The decision whether a particular offer from would-be adopters should be encouraged should be made by a body which receives many offers and is in a position to select. The paramount consideration should always be the welfare of the child, and *no adoption should be promoted for its possible therapeutic effects on the adopters*. The wise bringing up of an adopted child calls for great integrity of character and stability of purpose, especially during the strains of adolescence.

3 A mother should not be encouraged to consent to the proposed adoption of her child under any duress of circumstance or family pressure, or to arrive at a final decision while she is still pregnant or before she has fully recovered from her confinement. It is not until her child is born that many a mother understands the strength of her own love for him, and she may afterwards bitterly regret and resent a separation from her child which she had previously seemed to desire. Parenthood, even unmarried parenthood, brings privileges as well as burdens, and to remove a child from his mother is not only to relieve her of a burden, it is to rob her of a privilege and maybe to inflict a wound on the integrity of her nature.

Where circumstances seem at first sight too difficult to permit a mother's bringing up of her own child, the National Council for the Unmarried Mother and her Child, 21, Coram Street, London, WC1, or the Scottish Council for the Unmarried Mother and her Child, 17, Wester Coates Avenue, Edinburgh, 12, should be consulted. Through these bodies and the local societies working with them many mothers of all social types and degrees of education are helped to rise to the responsibility and some measure of the privilege of their motherhood. Sometimes, though much less often than the inexperienced might suppose, the adoption of the child is the right ultimate solution, but always with proper safeguards and never in a hurry.—I am, etc.,

Physiological Basis of Vagotomy

SIR,—Mr. A. Davis Beattie (April 9, p. 607) attempts to justify vagotomy as a physiological procedure for the treatment of peptic ulcer by relying on the neurogenic elements of its aetiology. He admits, however, that ulcer may occur both in the asthenic and sthenic types, and rejects the inborn diathesis in favour of a psychosomatic type with parasympathetic preponderance brought about by nervous stress. He refers to the work of McCrea and his associates, who emphasize that there is no true antagonism between the vagus and the sympathetic nerves. McCrea¹ states:

"Each nerve is undoubtedly both efferent and afferent, transmitting centrifugal and centripetal impulses, and concerned with motor, vasomotor, secretory, and sensory functions of the organ . . . The cutting out of one system of regulators (therefore) gradually results in the diminution and in almost a disappearance of control by the remaining system, the final results approaching but not attaining the effects of section of both. In this complete denervation, the intrinsic automatic mechanism takes on the proper functioning of the stomach no longer guided by external reflexes."

McCrea points out that the disorders of gastric function may be produced by either hypo- or hyperfunction of the extrinsic nerves, and that the primary cause which gives rise to such disorders may be located (1) peripherally, (2) in the nerve paths, or (3) centrally. To take these in reverse order: disorders of central origin may be constitutional, as suggested by Eppinger and Hess, and are possibly a result of endocrine instability; there is no evidence that they ever result in peptic ulcer formation. Disorders of the nerve paths are obviously too rare to be taken into serious consideration. The peripheral irritation, according to McCrea, is the most common cause, and is the result of inflammation which he rightly interprets as the pre-ulcerative stage.

This inflammation cannot be produced by the secretory response of vagal stimulation since acid by itself cannot produce the ulcer, and Beattie recalls that Dragstedt has shown that peristaltic activity and gastric secretion alone are not sufficient to delay physiological healing. It cannot be too strongly emphasized that the cause which is responsible for the local inflammation (which starts in the mucous membrane) is also responsible for the initiation of the ulcer and the maintenance of its chronicity.

In which way then, may it be asked, does vagal section arrest the progress of this morbid process, and what mechanism will be available to record whatever may go wrong in the stomach, since its immediate effect is the abolition of pain? It is difficult to follow the argument that by severing the stomach from its vagal control it can be claimed that there is "physiological basis for vagotomy."—I am, etc.,

Artificial Insemination

SIR,—In his letter (April 2, p. 590) Dr. Robert Forbes again refers to the Archbishop of Canterbury's Commission on Artificial Insemination. This was a mixed body of clergy and laymen—among the latter lawyers—whose sole dissentient from findings otherwise unanimous and unacceptable to Dr. Forbes was one of the clergy, the Dean of St Paul's. He further ignores that the whole Commission, including the Dean, had nothing to say against artificial insemination by the husband's semen. This is not fair controversy.

All systems of jurisprudence have admitted the existence of two systems of law: one called the Divine, or God's, or natural; the other that of the realm or State. Apart from any theory as to the origin of the former, a court of the latter can and will on due occasion hold that what may or may not be right or admissible in the latter is contrary to the natural rights of the person or persons concerned and therefore inadmissible.

Whatever system of natural or Divine law any system of jurisprudence admits, it ordinarily holds that law is unalterable and all that remains is to ascertain what it is. The proper persons to enunciate what on any particular point it lays down are clearly those concerned principally with the system in question; and in this country the division which arose about four centuries ago between the clerical and the legal profession

leaves the clergy with the duty concerned. Once the Divine law on any particular matter is known it is open to the different States of the world to leave their individual systems in accord or discord with it, or to bring them into accord or discord, as the State chooses. The risk of a divided loyalty on the part of its subjects, who in the last resort, all experience shows, will obey the law of God rather than the law of man, is wittingly run by the State which chooses discord.

In the debate in the House of Lords to which Dr. Forbes refers it appeared common ground that artificial insemination by a donor's semen constitutes adultery until doubt was thrown upon this view by, I believe, Lord Merriman. This is also the view of the Archbishop's Commission with the exception of the Dean of St. Paul's. Adultery in some systems of State law has been both a criminal and a civil offence (that is, an offence against the State and also against the offended spouse); in others, among them our own, it is a civil offence, the remedy being divorce, but no criminal penalty attaching. But in every system of Divine law adultery has in one way or another been regarded as sinful. The Greeks, whom we revere as the fathers of medicine, worshipped (practically as well as by offering and oblation upon her altars) a goddess of fornication whom they admitted had no power over the goddess of the home and who was at constant enmity with the goddess of the marriage bed and of childbirth in wedlock.

It is therefore incorrect to say that the doctor in attendance alone can determine whether A.I.D. is fitting and proper. He is no more entitled than anyone else to transgress either the Divine or the secular law. No matter how many legal precautions may be advised by Dr. Forbes or used by the practitioner, either he is doing right or he is doing wrong; and with exceptions only of individuals on certain relatively minor points all who have examined this subject consider he is doing wrong to advise or execute it. Answerably it is incorrect to say the law may require alteration. The Divine law can neither require nor receive alteration: it is laid down for ever. Our secular law on this matter appears in substance to be in accord with the Divine law; and if Dr. Forbes and his associates procure a deviation they are by so much further extending that discord between the Divine law and the law of the country already mentioned as a source of danger through the imposition of a divided loyalty.—I am, etc.,

London, S.W.6.

C. T. NORRIS.

SIR,—Whether Lord Merriman was right or wrong in describing as worthless the document approved by the Medical Defence Union for use by the parties concerned in A.I.D., his opinion coincides with that of the eminent legal experts who advised the Archbishop of Canterbury.¹ They state (p. 40) that the "assurance suggested by the Medical Defence Union as proper to be obtained by the doctor—that the birth of a child will not defeat the claims of any person to any titles, estates, interests, or funds—is one that could never be properly given or accepted."

This, however, is a matter that only the lawyers can settle. It is otherwise with the ethical aspects of A.I.D. Dr. Robert Forbes asserts (April 2, p. 590) that the "decision whether artificial insemination will constitute appropriate treatment for any given patient rests within the judgment of the doctor in attendance. He and he alone can determine whether or not it is fitting. . . ." But this is to beg the very question at issue: it is, in the last resort, society as a whole that must decide whether or not it is "fitting." Few can doubt that serious moral considerations are involved. Yet Dr. Forbes upbraids the Church for making its views plain before A.I.D. has been "properly examined by competent authorities and either condemned or confirmed." Who these authorities are and by what standards they are to "condemn" or "confirm" Dr. Forbes does not say. But to condemn the Church for forming its own judgment, after taking into account all the available evidence—medical, social, legal, and psychological—is surely illogical. If the Church is not a "competent authority" in such a matter as this, with the right to declare its views, will Dr. Forbes tell us why?—I am, etc.,

Redhill, Surrey.

Painless Childbirth

SIR,—The subjects of painless childbirth and analgesia are very much in the forefront at present in the Press and in parliamentary circles. Varying opinions have been expressed as to the relative merits of different agents and whether it is advisable to allow midwives to be equipped with "trilene" inhalers.

I should like to express my appreciation of the Minnitt gas-air apparatus, which is the one in use most frequently at present. This apparatus, designed by Dr. Minnitt, does just what is claimed for it. It provides a safe and suitable method of analgesia for use by midwives when no doctor is present.

According to the Central Midwives Board regulations, the midwife must be accompanied by an assistant when analgesia is to be administered. The most important part of the midwife's duty is the delivery of the baby, and a method of analgesia which had a definite risk to the mother would demand too much of her attention at a critical point in the conduct of the case. With the exception of the small percentage of non-cooperative patients, the rule is to find that patients express appreciation of the relief afforded by this method of analgesia. Transport difficulties seem to be the stumbling block, since the apparatus is somewhat heavy to carry.

There are two attachments for use with the Minnitt apparatus which enhance its analgesic effect and still keep the apparatus within the limits of safety. One is the Chassar Moir attachment, which allows the patient to have a few breaths of pure nitrous oxide followed by the 50% gas-air mixture. This initial nitrous oxide deepens the analgesic effect at the right point, and yet recovery from it is rapid. This method is very suitable for the time when, as a rule, inhalation analgesia is commenced—that is, towards the end of the first stage. There is a sufficient interval between pains for the reservoir bag to refill.

The other supplementary method is the Rowbotham bottle with a Walton fitting, into which 6 dr. (21 ml.) of trilene is placed. This method was demonstrated to me by Dr. Minnitt and I have used it in a considerable number of cases. In the second stage, and for delivery, the gas-air mixture is diverted over the surface of the trilene and affords marked relief.

Midwives receive a very comprehensive and excellent training, and a high standard of proficiency is demanded from them at the end of it. Analgesia is now included in the curriculum. The two supplementary methods I have mentioned for use with the Minnitt apparatus could be included in the category of safe and suitable methods for the trained midwife.

From my experience of observing their work in hospital I should say that they are very careful when using analgesia and tend towards under- rather than overdosage. They could have a somewhat wider range than at present to help them in conducting the normal midwifery which is their province. I do not think that they would abuse the privilege or that any harm would come to the mother or infant.—I am, etc.,

Beardsden, Glasgow.

ELLEN COWAN.

Psychiatric Indications for Abortion

SIR,—The annotation (March 19, p. 489) entitled "Psychiatric Indications for Abortion," arising from changes in Swiss law, is of great interest. I hope I may be permitted to comment upon certain points.

1. Where pregnancy is the result of rape, the fact of rape does not in itself constitute a reason for termination. The mental strain consequent upon the birth of a child so conceived must, however, be a potent factor in determining the post-natal condition of the mother's psychic, and therefore also her physical, health. That this view is admissible under English law was upheld by Mr. Justice Macnaughten in the Bourne case (reported in the *Journal* of July 23, 1938, p. 199). Considered in this sense the Swiss law does not seem dissimilar.

2. It is very hard for a socialized State to admit that economic grounds for termination can exist. Here again, however, under even the best social safeguards very great inequalities must always continue. As your annotation rightly points out, no system of family allowances and maternity benefits can be adequate for the over-prolific family. The income which is reasonable for the average family, providing not only shelter, clothing, and food but the opportunity of rest and convalescence for the mother, will not be enough to secure the same benefits as the mother with repeated pregnancies—whose need is none the less the greater.

3. When the question of defining admissible psychiatric grounds is raised, we are upon even more uncertain terrain. As Dr. Ellis Stungo (April 2, p. 590) very sensibly points out, each case must be considered upon its merits. Those "merits" cannot be judged only from the patient as a "body," or even as a "mind," without consideration of the total picture.

How did the act of conception come about? In what sense is the mother, married or unmarried, emotionally involved with the father? Is the mother, if unmarried or deserted, on good terms with her parents, or has she friends who can accept the situation? Will the emotional trauma likely in many cases to follow thwarted motherhood have greater repercussions in the long run than the immediate difficulties leading to the request for termination? These are some of the questions which must be faced. In order to face them the doctors concerned cannot be too fully informed regarding every aspect of the background. This is where the "family doctor" can be invaluable and by his information and advice has it in his power to contribute enormously to the prevention of much misery.

4. Where a patient is in so disturbed a mental condition as to warrant continual watching for the prevention of suicide, that in itself would seem to be strong evidence of such severe mental conflict as may lead to complete breakdown. I would, however, like to put on record my disagreement with Dr. Stungo that in doubtful cases it is always wiser not to resort to termination, but to endeavour to reconcile the expectant mother with the reality factors of her situation. In genuinely doubtful cases I consider it wiser to give the mother the benefit of the doubt.

I should like to conclude by asking you, Sir, whether it might not be appropriate for medical men throughout the country to seek the establishment of a Royal Commission to investigate and, if possible, to suggest amendments of the law concerning termination of pregnancy. There can be few doctors, and even members of the general public, who do not feel it an anomaly, that pregnancies, the result of positively illegal acts—e.g., rape or seduction of a girl below the age of consent—cannot be terminated, if the demand is made, *upon that ground alone*. Similar considerations would seem to apply in the case of insane patients desirous of termination, and in those instances where congenital syphilis or a long-standing family history of insanity make it reasonably certain that the offspring will be tainted—with consequent serious repercussions upon the mother, the child, and the community as a whole.

It would also protect doctors and safeguard the general well-being of the mothers of the nation if at the same time the whole question of psychiatric indications for abortion could be submitted to public examination with suggested positive reforms in law.—I am, etc.,

London, W.1.

EUSTACE CHESSEY.

POINTS FROM LETTERS

Prescription of Barbiturates

Dr. NATHAN FINN (Johannesburg) writes: Dr. H. H. Margulies (Feb. 19, p. 325) in his constructive criticism of my communication (Jan. 29, p. 195) exaggerated the emetic dose of *pulv. ipécac.* In my experience many people complain of nausea even after $\frac{1}{2}$ gr. (5.4 mg.), and many actually vomit from such a dose. In my humble opinion, shared perhaps by others, there is some contradiction in the arguments put forward by Dr. Margulies, who does not tell us if his statements were made from observations on patients. Theoretically he may be right, but every theory must be proved, otherwise it just remains a theory utterly useless to a practitioner. The question is one of great practical importance. The solution cannot be to stop prescribing a so well-established and also most useful preparation. In my experience "ersatz" preparations are far from satisfactory.

Irreducible Umbilical Hernia in Pregnancy

Dr. MARGARET M. NOLAN (Anua, S. Nigeria) writes: On July 16, 1948, an Anang woman of the Calabar Province, aged about 26, was admitted to the antenatal ward. She was 5 months pregnant and was complaining of much pain in the umbilical region. On examination she was found to have a medium umbilical hernia which was tender but apparently reducible. On Aug. 2 she complained of no bowel movement for 24 hours, and she had much abdominal pain; the hernia was now irreducible. After an injection of "omnupon" $\frac{1}{2}$ gr. (22 mg.) and under local infiltration with "nupercaine," the hernial sac was isolated and removed with a portion of adhering gangrenous omentum. The hernia was repaired according to the Mayo technique, chromic catgut No. 0 being used. The wound healed by first intention. The pregnancy continued to term, the patient having a normal delivery of a living female infant weighing 6 $\frac{1}{2}$ lb. (2.8 kg.) on Jan. 2, 1949. The puerperium was normal, and the patient went home on the tenth day.

Obituary

JOHN W. BONE, LL.D., M.B., C.M.

Dr. John W. Bone, whose record of service for the British Medical Association was outstanding, died at his home in Luton on April 14 at the age of 79. He had been treasurer for nine difficult years, and for thirteen years before that he had been chairman of the Medico-Political Committee, which afterwards became the General Practice Committee.

John Wardle Bone was born in 1869, and in 1891 he graduated M.B., C.M. with first-class honours at the University of Edinburgh. Four years later he took the B.Sc. in public health. After serving in some resident appointments, including one at Clayton Hospital, Wakefield, he settled in general practice at Luton in Bedfordshire. He was kindly and painstaking, and yet the sort of man who would "stand no nonsense," and he had an admirable way with him, particularly in dealing with children. From 1896 onwards he was closely identified with the Luton Children's Hospital, though he did not actually receive a staff appointment there until 1899. In 1905 he became honorary medical superintendent of the hospital, and during his tenure of office he was responsible for various extensions and improvements. He resigned the position of medical superintendent in 1933, while remaining a member of the committee of management and continuing to take a great interest in the hospital. He was also honorary consulting surgeon to the Bute Hospital, Luton, and a co-opted member of the maternity and child-welfare committee of the town council.

Dr. Bone did not become a member of the British Medical Association until 1905, but he quickly made his personality felt in his own Division, of which he was chairman in 1910. He also represented the Bedfordshire and Hertfordshire Division at annual representative meetings from 1911 onwards, and entered the Council in 1920. In 1922 he was president of the South Midland Branch. When the Association was called upon to choose from a number of candidates the two who should have its support at the 1928 election of direct representatives for England on the General Medical Council, Dr. Bone was one of those selected, the other being the late Sir Kaye Le Fleming; both were returned by large majorities. On the General Medical Council he was a very active member and most skilful in the examination of witnesses. Often after counsel on both sides had completed their examination Dr. Bone would rise and with a few questions, asked through the chair, give a quite fresh aspect to the case.

He was not a great platform man, and confessed that he was never happy with the microphone in large assemblies, but he was an ideal member of committees. His tongue was occasionally caustic and his manner dour, and when in the chair he never concealed his impatience at undue protraction of the business. Nevertheless, he had a great sense of fun, and his delight in some quip would often relieve a tedious afternoon. The gradual serpentine movement of committee procedure really interested him; he knew that it was there, and not in larger and more showy gatherings, that the business was done. His work for the British Medical Association in the committee-room, usually at Headquarters but sometimes at the House of Commons or on deputations to Government Departments, was of great value. His own contributions to debate were always persuasive and critical, and he had the capacity for working in a team and throwing his whole weight into a cause.

The list of John Bone's Headquarters activities would run parallel with the medico-political activities of the Association

from 1920 onwards. In addition to his work in the General Practice Committee, which at one time had as many as twenty subcommittees, he had been a member at various times of the Central Ethical Committee, of the committee concerned with certification under the Workmen's Compensation Act, of the committees on Health Services, on Lunacy Law and Mental Disorder, on Medical Education, on Poor Law Reform, and many others. Bone's membership of the Insurance Acts Committee dated from 1923, and there again he served on a bewildering number of subcommittees. A useful piece of work in which he took particular interest was his chairmanship of the committee which put up so effective an opposition to the Osteopaths Registration Bill when it came before the Select Committee of the House of Lords in 1935. On all questions connected with pharmacy and dangerous drugs he was an acknowledged expert. He was a member of the Advisory Committee on the Pharmacy and Poisons Act, known as the Poisons Board, and brought to the work a surprising amount of detailed knowledge. Earlier he had been a member of the watching committee set up by the Association in regard to the revision of the *British Pharmacopoeia*. He was also one of the five members nominated by the Association on the Board of Directors of the British Medical Bureau. Another excellent achievement was his part in the settlement of the dispute at Llanelli, which arose in 1934 between the local profession and the Workmen's Committee. He was one of the three or four representatives of the Association who visited the area and spent three days in hearing evidence and making the fullest possible local inquiries.

Dr. Bone was a man of considerable business sagacity. He succeeded the late Mr. Bishop Harman as Treasurer of the Association, and for nine years showed his mastery of the financial policy of a great organization. His treasurership included the anxious period of the second world war, when important decisions had to be made almost from day to day. He managed to combine, in a way that carried general approval, a firm control of expenditure with a policy of expansion adapted to meet the great demands on the Association which he foresaw as likely to arise in the post-war years. His presentation of the financial report year by year was never seriously criticized. He was also treasurer of the National Insurance Defence Fund, and one of the treasurers of the General Medical Council.

At the Cambridge meeting in 1948, when he retired from the treasurership, the Council unanimously decided to award him the Gold Medal of the Association for his exceptional services—a decision which evoked enthusiastic approval when it was announced to the Annual Representative Meeting. In 1946 Dr. Bone received the Hon. LL.D. of his own University of Edinburgh.

Dr. Alfred Cox writes: For some weeks now Dr. Bone's old friends have been sorrowfully awaiting the inevitable end, but nevertheless it is very sad to think that B.M.A. House will see him no more. For many years, as is well shown by the preceding narrative, he was there nearly every day and there were few of the Association's activities in which he did not take an active part. He was not easy to know intimately. He had the old-fashioned idea that a man's private life was his business, and would have resented intrusions on it. But it was a pleasant revelation to see him at home as I did occasionally when he was in active practice. We had some kindred interests which helped me to get behind the somewhat "dour" Bone. He was a North Countryman and could always be drawn on his early days in the North. He never got rid of his Northumbrian "burr" and never tried. He was a great collector of books, which, unlike some collectors, he read, and he could talk, and talk well, about his favourites. I should put Bone high among the men of business capacity who have served the Association. He was eminently a man of orderly and logical mind and hated waste, though he could always be converted to approval of large expenditure by the Association once he saw its possibilities. This was brought out before he became treasurer in the enthusiastic support he gave to his old friend Sir Robert Bolam when he fathered the ambitious scheme for the extension of B.M.A. House. From what I saw of his methods of practice it did not surprise me to learn that he had built up one of the most successful general practices in the provinces. Bone was no lover of the limelight—nor indeed of those who obviously sought it. But he was sound all through, and no man ever more faithfully earned the Gold Medal of the Association. It is a

grief to all his friends that he never received it in due form amidst the applause of all of us who knew him and who would have been delighted to have been able to say to him, "Well done, good and faithful servant."

DONALD GEORGE HALL, M.D., F.R.C.P.

Dr. Donald Hall died very suddenly at his home in Hove on April 7 from coronary thrombosis at the age of 72. His early years were spent at Gatehouse-of-Fleet, a lovely spot in Kirkcudbrightshire, where was nurtured his intense attachment to his native land. He was educated at the Edinburgh Academy, and from there gained a scholarship in natural science at Emmanuel College, Cambridge, where in 1897 he took a first-class tripos in the same subject. Returning to Edinburgh to complete his medical course, he graduated M.B., B.Ch. in 1900. There followed resident appointments at the Royal Infirmary and the Royal Hospital for Sick Children, Edinburgh, and then, like many a Scot, Hall migrated southwards and became house-physician at the Royal Sussex County Hospital, Brighton. Subsequently he put up his plate in Hove, and thus began a general practice which was later to bring him such a well-deserved reputation.

In 1903 Hall proceeded M.D., and in the following year he was elected assistant physician to the Royal Sussex County Hospital. Soon after the 1914-18 war he began to make a special study of the treatment of pulmonary tuberculosis by artificial pneumothorax, and of the use of the electrocardiograph. He became a recognized authority on both subjects, and his election in 1945 as chairman of the Cardiac Society of Great Britain and Ireland was a tribute to his profound knowledge of the diseases of the heart. Dr. Hall was elected F.R.C.P. in 1923 and thenceforth confined himself to consulting practice. He was the trusted adviser of an ever-widening circle of doctors and their patients, and the esteem in which he was held was reflected in the frequency with which his colleagues called upon his help in their own illnesses and those of their families.

Donald Hall was an able physician and consultant. Kindly and inspiring confidence, he had a remarkable memory which enhanced the value of his wide experience, his incisive mind, and a sure clinical instinct. His opinion and advice were equally clear and decided, and whenever possible he offered a reassuring and optimistic outlook to the patient. When the chairmanship of the Royal Sussex County Hospital became vacant in 1938, Hall, though still an active member of the honorary staff, was unanimously elected to this important and onerous post. He filled it with conspicuous success for eight years, and it was largely due to his wise guidance that the hospital was able to fulfil its many obligations during the difficult years of the recent war. In 1946 his services to the hospital were recognized by his appointment as its president. Hall was president of the Brighton and Sussex Medico-Chirurgical Society in 1927, chairman of the Brighton Division of the B.M.A. in 1926-7 and again in 1931-2, and president of the Sussex Branch in 1933-4. In the Boer War he had served on the hospital ship *Nubia*, and in the 1914-18 war in the Second Eastern Hospital, with the rank of major. In his younger days he captained his college rugby team, and later played forward for the famous Edinburgh Academical side, which included several internationals. Hall was a good shot and a keen fisherman. For many years he spent his holidays shooting and fishing in Scotland or Northumberland with his friends. Many will remember his and Mrs. Hall's hospitality and kindly thoughtfulness on these occasions. His family circle was ideally happy, and in all he did he was constantly supported by his wife. For her and her family deep sympathy will be felt by many friends. For forty-four years Donald Hall devoted his great gifts to his hospital, its patients, its nurses, and to many others. The gratitude and affection he inspired will not soon be forgotten.

A. HEDLEY VISICK, F.R.C.S.

Mr. Arthur Hedley Visick died after a brief illness at York on April 4 at the early age of 51. He came of a medical family. His father was well known in North London as an anaesthetist, and on his mother's side he was related to Sir Albert Cook and the late Mr. J. Howard Cook, of Uganda. He was educated at Epsom College and St. Bartholomew's Hospital, gaining an entrance scholarship there in 1915. He

did not take up his studies, however, until 1918, as he served in the Army during the war. From the first Hedley Visick showed his interest in surgery. He won easily the Treasurer's prize and later the Foster prize for anatomy. In his final year he had the unusual distinction of being awarded the Walsham prize and the Brackenbury surgical scholarship as well as the Willett medal for operative surgery. He qualified in 1922, and served as house-surgeon first to Sir Holburt Waring and then to the ear, nose, and throat department at St. Bartholomew's. He graduated M.B., B.S. in 1924, and immediately afterwards took the F.R.C.S. He then gained valuable surgical experience as chief assistant to Sir Charles Gordon-Watson and demonstrator of anatomy at St. Bartholomew's. In 1926 he went to Michigan as an instructor in surgery at the university there. After this year in America he settled in York, and in due course was put on the staff of the York County Hospital and was made surgical specialist to the Military Hospital. He was also consulting surgeon to the York City Hospital and to a number of smaller outlying hospitals.

From his earliest days as a medical student Visick had set his heart on being a surgeon. Even before he qualified he used to watch surgeons at work in other hospitals. This he continued to do at all stages of his career: he would often come up to London for a few days for this purpose. He was a keen and regular member of the surgical travelling club to which he belonged. When Hedley Visick started in York it was as a general practitioner, but he gradually did more surgery, gave up general practice completely, and quickly built up a reputation not only in York but in a wide area around the city as a first-rate surgeon. At first he interested himself in thyroid surgery, but over the last ten years he became especially expert in gastric surgery and was well known for his work on this subject. As a Hunterian professor at the College of Surgeons last year he lectured on gastrectomy, and he contributed to this and other journals a number of thoughtful and valuable articles on the surgery of peptic ulcer. His follow-up clinic was a model of completeness in detailed record-keeping. Every Wednesday, with medical and radiological colleagues, he personally saw all the patients who attended this clinic. Each interview and examination was quick and informal but thorough. Each patient was called by his Christian name and was glad to come. In his earlier days Visick was an unusually good teacher, while in later years he showed the same ability as a lecturer.

One of Hedley Visick's characteristics was his great and genuine enthusiasm for any subject he took up. This was combined with an excellent pair of hands, which made his operating a pleasure to watch. He was a man of even temper who greatly delighted in meeting old friends and making new ones. He was highly esteemed by his colleagues, and from 1938 to 1943 he acted as chairman of the York Division of the B.M.A. The place he made for himself as a consulting surgeon in York will not easily be filled. He was very happy with his family at his old house at Fulford and at his cottage in the country. The sympathy of all his colleagues and friends will be given to his wife and three children.

MAURICE SORSBY, M.D., F.R.C.S.Ed.

Dr. Maurice Sorsby, who died at Los Angeles on April 6 at the age of 50, qualified M.B., Ch.B. at Leeds in 1922, proceeding M.D. in 1925. In the same year he also obtained the Edinburgh F.R.C.S. Devoting himself to otolaryngology, he held staff appointments at the Metropolitan Ear, Nose and Throat Hospital, the London Jewish Hospital, and the Plaistow Children's Hospital. He was also for a time consulting ear, nose, and throat surgeon to the L.C.C. hospitals. A sound early training in general surgery turned his interest mainly to the intracranial complications of ear disease and to the general aspects of the cancer problem. His study of the incidence of cancer in Jews, embodied in his excellent *Cancer and Race*, was a valuable contribution to a subject on which previously there had been more opinions than critical data. This detailed study of the incidence of cancer in Jewish communities in different parts of the world showed that the total cancer rate in Jews was everywhere approximately the same as that of the general population, though the distribution according to the organs affected varied considerably. These latter differences could in most

cases be explained by environmental factors. The low incidence of cancer of the tongue, for instance, could be correlated with a low incidence of syphilitic leucoplakia, which so often precedes it. Maurice Sorsby's study on Beethoven's deafness was characteristic of his wide interests, and a busy professional career still left him time for much social activity. As a president of the London Jewish Hospital Medical Society he was largely instrumental, together with the late Dr. M. D. Eder, in forming the Emergency Medical and Dental Association for the relief of victims of Nazi persecution in the years before the war. A large circle of friends will feel sympathy with his widow and his two sons.

Medico-Legal

DAMAGES FOR A DOCTOR

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Dr. L. M. Billingham, of Great Waltham, Chelmsford, was run down by an Army vehicle on Nov. 28, 1947, and suffered serious injuries, including a fractured pelvis. He had previously worked in general practice and as a radiologist; as a result he was physically unfit for general practice but not for radiology.

In the action which he brought in the High Court against the driver and the War Office, Mr. Justice Croom-Johnson awarded him £4,000 damages for pain and suffering and £20,000 compensation for estimated loss of earnings for the remainder of his working life. This amount was computed on the basis of £2,000 loss of earnings for each of fifteen more years, less £10,000 to allow for contingencies, his increased earnings as a radiologist, and the large capital sum down which he was to receive. The defendants appealed on the ground that the damages were excessive, and that the judge had failed to take into account the fact that the plaintiff's fees would have been reduced by taxation.

Lord Justice Tucker, giving judgment¹ in the Court of Appeal, said that the judge could not have given sufficient weight to the fact that the doctor could now devote the whole of his time to radiology. The court thought the amount awarded for loss of earning capacity should be halved, making the total damages £14,000 instead of £24,000.

On the second point, that the judge had failed to allow for the reduction of the doctor's fees by income tax, his lordship said that this argument had been rejected twice by High Court judges sitting alone but had never come to the Court of Appeal for decision. It had been accepted in a Scottish case, but he thought with respect that it was fallacious. The principle of *restitutio in integrum* required that the doctor should be put in the same position *vis à vis* his patients as that in which he would have been but for the fault of the defendants—that is, that he should receive his fees in full. Questions of ultimate liability to the Revenue did not concern the defendants, though different considerations might arise in cases of P.A.Y.E.

Lord Justice Singleton, agreeing, said that general damages for loss of future earnings would not be subject to income tax, but that in assessing them no reduction should be made in respect of the tax which would have been payable on such earnings. He thought that cases of P.A.Y.E. would be in the same position. Mr. Justice Birkett concurred.

This action, incidentally, is a reminder of the convenience of the reform introduced by the Proceedings against the Crown Act last year, whereby a Government department can now be sued in the same way as a subject of the King, and the cumbersome procedure by petition of right is no more.

¹ *The Times*, March 11, 1949

H.M. Customs and Excise state that from April 5 preparations appearing in the *National Formulary*, whether or not compounded with substances appearing in the monographs and formularies of the other publications specified in Provision 1 of Notice 78 M, or with an excipient, vehicle, base, or preservative, are exempt from purchase tax so long as they comply with the remaining provisions of Notice 78 M or 78 N.

PREGNAVITE

**A single* supplement
for safer pregnancy**

CLINICAL USES

To improve the nutritional state where circumstances prevent consumption of all the protective foods required to prevent hypochromic anaemia.

Indications in the history of previous pregnancies: toxæmia, previous premature births, inability to breast feed, and dental caries.

* The recommended daily dose provides: vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B₁ 0.6 mg., vitamin C 20 mg., vitamin E 1 mg., nicotinamide 25 mg., calc. phosph. 480 mg., ferr. sulph. exsicc. 204 mg., iodine, manganese, copper, not less than 10 p.p.m. each.

TEMPORIS ARS MEDICINA FERE EST (OVID)

The art of medicine is generally a question of time. With the peptic ulcer patient, as is well known, the rate of healing is determined by the ulcer's freedom from irritation. By rapidly buffering excess acid and at the same time avoiding acid rebound, 'ALUDROX,' a suspension of 5.6% colloidal aluminium hydroxide in gel form, ensures rest for the ulcer. Pain is relieved and time taken for healing reduced to a minimum.

ALUDROX

Subtleties of shadow

FINE shades and distinctions seldom count so much as in the interpretation of a radiograph. Indeed, the ultimate diagnosis may well hinge on a subtlety of shadow only revealed when adequate density and definition have been obtained. To aid in achieving these criteria Glaxo contrast media cover a wide radiographic field. From this range the preparation best suited to individual diagnostic requirements can be nicely selected. Pyelosil ' and 'Pyelectan' are the two standard preparations for excretion pyelography; and recently, Visco-Pyelosil ' has been introduced for salpingography—in particular, for the investigation of sterility. In radiography of the gall bladder by the "single-dose" technique, Pneumodol Glaxo provides a safe and reliable contrast medium, while for detection of abnormalities affecting the spinal column, 'Myodil' affords successful visualisation without fear of irritation or arachnoiditis.

PYELOSIL

Brand solution of Diodone
25% and 50% solutions: 20 cc
ampoules. Also 70% solution
especially for card i-angiography
20 cc and 50 cc ampoules.

VISCO-PYELOSIL

Brand Viscous solution
of Diodone:
10 cc & 5 x 10 cc ampoules

PYELECTAN

Brand injection of Iodoxyl
20 cc & 5 x 20 cc ampoules.
Pyelectan (Retrograde) 10 cc

PNEUMODOL Glaxo

Granules, 6 gram tube (1 dose)
Tablets, tube of 6 (1 dose)

MYODIL

Brand Ethyl
iodophenylundecylate
3 x 3 cc ampoules.

GLAXO

GLAXO LABORATORIES LTD., GREENFORD, MIDD. BYR07 3434

An anti-histamine of wide application

HISTOSTAB is one of the most satisfactory antidotes for histamine now available.

In the treatment of a wide range of allergic conditions Histostab has few undesirable side-effects. It may be given orally, or by injection when rapid action is required. It will control allergic urticaria and eczema, and will relieve the itching in certain cases of pruritis. It has proved of value in cases of sensitivity to Insulin, Liver and Penicillin, suppressing the unpleasant effects and allowing treatment to be continued.

As Compound Solution of Histostab it is available for nasal and ocular instillation in vasomotor rhinitis and hay fever.

Histostab Tablets. Bottles of 25 x 0.1 G. tablets.

Injection of Histostab. Boxes of 6 ampoules of 2 ml. (0.1 G.).

Solution of Histostab Compound. Bottles of $\frac{1}{2}$ fl. oz.

HISTOSTAB

Vitamin B₁₂ in

Anahæmin
B.D.H.

Microphotograph of the anti-pernicious anemia (A.P.A.) factor, vitamin B₁₂, isolated from Anahæmin B.D.H.

Although the potency of each batch of Anahæmin B.D.H. has always been established clinically before issue, further confirmation of its hæmopoietic activity is now afforded by the isolation of the anti-pernicious anemia factor in crystalline form from routine batches of Anahæmin B.D.H. in the B.D.H. Research Laboratories*. This factor is identical with the substance named vitamin B₁₂ by Rickes *et al.*† Since its introduction twelve years ago Anahæmin B.D.H. has given outstanding results in the treatment of macrocytic anæmias.

GLYCODEINE

GLYCODEINE IS A VALUABLE SEDATIVE FOR THE RELIEF OF IRRITABLE COUGH, ESPECIALLY IN PHTHISIS, BRONCHITIS AND DYSPNOEA.

IT IS ALSO A USEFUL LINCTUS FOR THE TREATMENT OF ASTHMA AND LARYNGITIS.

GLYCODEINE IS EXEMPT FROM THE REGULATIONS OF THE DANGEROUS DRUGS ACT.

*GRANULA. Codeinæ Phosp. 0.4, Liq. Tolu 13.5, Syr. Prunl Seros. 13.5, Glycerin ad 100
 Each dram contains $\frac{1}{2}$ grain Codeine Phosphate.

It is supplied for dispensing in bottles of $\frac{1}{2}$ lb. and 1 lb. in bulk.

BLANDFIELD CHEMICAL WORKS · EDINBURGH

ALSO AT LONDON AND GLASGOW

Mr BEVAN said that merchant seamen, like anyone else who went abroad, were unable to obtain treatment under the National Health Service Act while out of this country. The Government intended to negotiate reciprocal arrangements with other countries wherever the opportunity arose. He thought that one such arrangement was being negotiated at the moment.

No. 13

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 2.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Smallpox

As was anticipated in these notes (April 9, p. 640), there have been further cases of smallpox following the infection and death of a passenger on the s.s. *Mooltan*. Among the persons exposed to infection while on board the following secondary cases have been reported. The notifying authority and the date of onset of illness are given in each case: Port of London, 3.4.49; Paddington M.B., 5.4.49; St. Pancras M.B., 5.4.49; Isle of Axholme R.D.C., 5.4.49; Paddington M.B., 6.4.49; Liverpool C.B., 6.4.49; Wembley Borough, 7.4.49; Sutton and Cheam Borough, 7.4.49; Torquay Borough, 8.4.49; Aylesbury Borough, 12.4.49; and Richmond Borough, 12.4.49. There is still some uncertainty about the diagnosis in patients reported from South wark M.B. and Abertillery. In many other persons who travelled on the s.s. *Mooltan* and who subsequently came under observation the suspicion of smallpox has not been confirmed. The above list contains information available up to April 19, when all the confirmed cases of smallpox in England and Wales had been in contact on the s.s. *Mooltan* and should therefore be considered as imported cases. In other words, there have so far been no secondary cases infected in this country. These are expected to appear at any time.

The disease is a severe form of *variola major*. Five of the patients have died, two of them in the prodromal stage. The disease has been haemorrhagic in some; with others there has been extreme modification resulting from vaccination.

Suspected Smallpox

Two patients are under observation at Lacey Smallpox Hospital. They are in no way associated with the s.s. *Mooltan* and furthermore the diagnosis is uncertain. They come from Brigg and Bolton-on-Deane and were taken ill on April 13 and 14, respectively.

Discussion of Table

In England and Wales increases were recorded in the notifications of measles 512 and dysentery 28. There were decreases in the incidence of scarlet fever 100 and acute pneumonia 66.

After declining for four weeks the incidence of measles rose; the rise was mainly confined to the Home Counties. The largest increases in the notifications were Middlesex 260, London 213, Yorkshire West Riding 111, and Surrey 107; the largest decreases were Staffordshire 189 and Leicestershire 147.

A small decrease in the number of notifications of scarlet fever was recorded in most areas of the country; the only notable exception was a rise in Essex due to 62 cases in Billericay U.D. There were only very small fluctuations in the local trends of diphtheria. The only large variations in the local incidence of whooping-cough were rises in London 66 and Warwickshire 51.

No new outbreaks of dysentery were reported during the week. The increased incidence was due to scattered cases; 18 counties notified the presence of a case compared with 9 counties in the preceding week.

In Scotland an increase was recorded in the number of notifications of measles 56, whooping-cough 32, and scarlet fever 13. There were decreases in the incidence of acute primary pneumonia 32 and diphtheria 12. The rise in the notifications of scarlet fever was mainly due to the experience of the south-eastern area, and the decrease in the incidence of diphtheria occurred in the western area.

In Eire there were rises in the incidence of measles 36 and of diarrhoea and enteritis 15 and a fall of 20 in the notifications of scarlet fever. There were 28 cases of measles notified in Donegal, Stranorlar R.D.; otherwise these changes were mainly due to the experience of Dublin C.B.

In Northern Ireland the only appreciable change was a fall of 27 in the notifications of measles, due to a small decrease throughout the country.

Week Ending April 9

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,191, whooping-cough 2,608, diphtheria 106, measles 14,724, acute pneumonia 1,093, cerebrospinal fever 39, acute poliomyelitis 14, dysentery 63, smallpox 4, paratyphoid 5, and typhoid 1.

Charter Travelling Scholarships, value £300 for one year, have been awarded by the Pharmaceutical Society to Miss Joan Mary Rhodes, B.Pharm., Ph.C., of Worthing, to enable her to study the conditions of pharmaceutical practice in Denmark, and also, subject to his passing the final examination for the B.Sc. (Pharm.) Degree of the University of Manchester in the summer of 1949, to Robert Guest Baker, of Manchester, to study in New York. The Charter Travelling Scholarship was founded in 1943 to mark the 100th anniversary of the granting of a Royal Charter to the Society.

Medical News

Blood Test for Cancer

At the annual meeting of the American Association for Cancer Research, which was held in Detroit last week, Professor Charles B. Huggins, of the University of Chicago, is reported by the *Manchester Guardian* (April 18) to have described a blood test for cancer. The test is said to be based on a change in the coagulability of the serum of patients with cancer, "due to a disturbance in the albumin content." It is positive not only in cancer, but also in tuberculosis, lobar pneumonia, meningitis, and other acute infections. Associated with Professor Huggins in this work were Dr G. M. Miller and Dr E. V. Jensen.

Central Midwives Board

At its April meeting the Central Midwives Board re-elected Mr Arnold Walker as chairman and Mr J. P. Hedley as vice-chairman for the ensuing year.

American Conference on Handicapped Children

A conference sponsored by the Child Research Clinic of the Woods Schools, Langhorne, Pennsylvania, was held on April 22 to discuss the effect on handicapped children of the emotional attitudes of parents and such environmental influences as school, church, and community. The conference programme was under the direction of Dr Charlotte E. Grave, Director of the Woods Schools Child Research Clinic.

Linctus Diamorphinae

There is no linctus diamorphinae in the new *National Formulary*, which will replace the *National War Formulary* as from May 1. Pharmacists will therefore be unable, under the Dangerous Drugs Regulations, to dispense the *War Formulary* preparation unless the formula is written out in full. To overcome this difficulty the Pharmaceutical Society has released its formulae for the two linctuses which are scheduled for inclusion in the *B.P.C.* 1949, which has not yet been published. A notice of their composition appeared in the *Pharmaceutical Journal* of March 26. They are linctus diamorphinae *B.P.C.* (the same strength as the *N.W.F.* linctus but with a different base), and linctus diamorphinae et hyosciami *B.P.C.* After May 1, therefore, when a doctor prescribes linctus diamorphinae or linctus diamorphinae *N.W.F.*, pharmacists will dispense linctus diamorphinae *B.P.C.* unless a formula is written out in full.

Victor Horsley Memorial Lecture

The Victor Horsley Memorial Lecture is held triennially and is usually given about the time of Sir Victor Horsley's birthday, which is in July. The lecture this year will be delivered by Sir Hugh Cairns, K.B.E., D.M., F.R.C.S., Nuffield Professor of Surgery, Radcliffe Infirmary, Oxford. The lecture will be in December, under the chairmanship of Dr. F. M. R. Walshe, and the exact time and place will be announced later.

COMING EVENTS

Royal Medico-Psychological Association

A meeting of the Child Psychiatry Section of the Royal Medico-Psychological Association will be held at the Royal Society of Medicine (1, Wimpole Street, London, W.) to-day (Saturday, April 23), at 11.15 a.m., when Dr E. Mildred Creak and Dr Richard H. Dobbs will read papers on "The Psychiatric Aspects of Maternity and Child Welfare Work." At 2.15 p.m. papers will be read by Miss Anna Freud and Dr A. G. Watkins on "Effects of Hospitalization on the Child." Members of the British Paediatric Association, the Section of Paediatrics of the Royal Society of Medicine, and the Maternity and Child Welfare Section of the Society of Medical Officers of Health are invited to attend the meeting.

Edinburgh Lectures

A series of Honvman Gillespie Lectures in association with Edinburgh postgraduate courses will be given in the Anatomy Theatre, University New Buildings, Teviot Place, Edinburgh, on Thursdays, at 5 p.m., from April 28 to June 9 (except May 19). The lectures are open to all graduates and senior students, and details will be published week by week in the diary column of the *Journal*.

Care of Cripples

The Central Council for the Care of Cripples will hold a conference on "Planning the Future for the Physically Handicapped" on Friday, April 29, at the Conway Hall, Red Lion Square, London, W.C.1. Speakers include Mr H. Osmond Clarke and Dr G. S. Wiles. Information may be obtained from the Secretary of the Central Council, 34, Eccleston Square, London, S.W.1.

Wright-Fleming Institute of Microbiology

The following course of six Almoth Wright Lectures on "The Bacterial Cell" has been arranged for the Summer Session, 1949. They will be given in the Lecture Theatre of the Institute at St. Mary's Hospital on Tuesday afternoons at 5 p.m. May 3. Professor E. W. Rideal, F.R.S., "Surface Properties of Bacteria" May 10. Mr E. F. Gale, Ph.D., "Biochemical Properties of the Bacterial Cell Wall" May 17. Mr W. T. J. Morgan, F.R.S., Ph.D., "Bacterial Antigens" May 24. Dr M. R. Pollock, "Bacterial Nutrition" May 31. Mr F. C. Bawden, F.R.S., "The Nature of Plant Viruses" June 7. Dr A. S. McFarlane, "Electron Microscopy of Bacteria and Viruses." These lectures are open to all members of the medical profession and to all students in medical schools, without fee.

St. George's Hospital Medical School

A series of lecture demonstrations will be held in the large lecture theatre of St. George's Hospital Medical School (Hyde Park Corner, London, S.W.) on Thursdays, at 4.30 p.m., from May 5 to July 7, both dates inclusive. The series is open to all medical practitioners and senior medical students, without fee. Details will be published in the diary column of the *Journal* week by week.

Musical Recital

A recital on behalf of the Princess Tsahai Memorial Hospital will be given by the St. Michael's Singers on May 11 at 6 p.m. at the Church of St. Michael, Cornhill, London, E.C.3. More than half the equipment for the Memorial Hospital, which has been built at Addis Ababa by means of British subscriptions, has been shipped from England. More is still required, and donations will be gratefully received. They should be addressed to the Honorary Treasurers Lord Horder and Lord Amulree, c/o H. Reynolds and Co., 1, Bloomsbury Court, London, W.C.1.

Royal Medical Benevolent Fund

The annual general meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, Cavendish Square, London, W., on Friday, May 13, at 5.15 p.m., with the President, Lord Webb-Johnson, in the chair. The statement of accounts for 1948 will be presented and officials and committee of management elected for the ensuing year.

SOCIETIES AND LECTURES

Friday

LONDON UNIVERSITY—At King's College, Strand, W.C., April 22, 5.30 p.m., "Gas Phase Reactions of Organic Radicals" by Dr E. W. R. Steacie, Director of Division of Chemistry, National Research Council of Canada.

Saturday

BRITISH ASSOCIATION OF ALLERGISTS—At Medical Institution Mount Pleasant, Liverpool, April 23, 11.15 a.m., (1) "The Management of Some Allergic Manifestations of the Upper Respiratory Tract" by Dr R. Donald (Melbourne). (2) "Asthma in Childhood—Experiences in a Liverpool Play Clinic" by Dr C. A. Clarke. (3) "Some Aspects of Nasal Allergy" by Dr E. Travers. (4) "The Skin Reactions—Its Uses, Limitations and Standardization" by Dr D. B. Macaulay. (5) "The American Approach to Allergy" by Dr A. E. Bernstein.

Monday

HUNTERIAN SOCIETY—At Talbot Restaurant, 64 London Wall, E.C., April 25, 7 for 7.30 p.m., dinner and annual general meeting. "Speech Defects and Voice Affections" address by Mr H. St. John Rumsey.

LEEDS UNIVERSITY—At University Union (Riley-Smith Hall) April 25, 3 p.m., "Moyinhan and the Training for Surgery" Moyinhan Lecture by Professor G. Grey Turner.

LONDON UNIVERSITY—(1) At King's College, Strand, W.C., April 25, 5.30 p.m., "Gas Phase Reactions of Organic Radicals" by Dr E. W. R. Steacie, Director of Division of Chemistry, National Research Council of Canada. (2) At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., April 25, 5.30 p.m., "Bacteriophage and Antibiosis" by Professor A. Gratia (Liege).

LONDON UNIVERSITY COLLEGE—At Physiology Theatre, Gower Street, W.C., April 25, 4.45 p.m., "Selective Toxicity with Special Reference to the Nervous System" by Professor Adrien Albert.

WESTMINSTER—At Medicine, Meyerstein Lecture Theatre, S.W.—April 25, 5.20 p.m., "climico pathological meeting".

Tuesday

INSTITUTE OF LARYNGOLOGY AND OTOLARYNGOLOGY, 330-332, Gray's Inn Road, London, W.C., April 26, 2.30 p.m., "Malignant Diseases and Radiotherapy" by Mr W. A. Mill.

Wednesday

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE—At 28, Portland Place, London, W., April 27, 3.30 p.m., "Occupational Eye Diseases and Injuries" (2) Illustrated, by Mr Joseph Minton.

Thursday

EDINBURGH UNIVERSITY.—At Anatomy Theatre, University New Buildings, Teviot Place, April 28, 5 p.m., "A Workshop for Severely Disabled Men," Honyman Gillespie Lecture by Professor T. Ferguson.

FACULTY OF RADIOLOGISTS: THERAPY SECTION.—At British Institute of Radiology, 1, Wimpole Street, London, W., April 28, 8.15 p.m., S. by Dr. F. Gordon Spear.

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., April 28, 8.15 p.m., "Medico-Legal Aspects of the Problems of Everyday Dental Practice," joint paper by Surgeon Lieutenant-Commander John Bunyan, R.N.V.R., and Mr. C. W. Stidson Broadbent.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—April 28, 5 p.m., "Stomatodacal Ruminations. Clinical and Non-clinical," Hunterian Lecture by Professor Charles F. M. Saint (late Professor of Surgery in the University of Capetown).

Friday

FACULTY OF RADIOLOGISTS: THERAPY SECTION.—April 29, joint meeting with Section of Radiology, Royal Society of Medicine, Discussion: "The Method of Presentation of Results in the Treatment of Cancer." (1) At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., 2.15 p.m., to be opened by Professor B. W. Windyey and Drs. J. S. Fulton and Percy Stocks. (2) At Royal Society of Medicine, 1, Wimpole Street, London, W., 8.15 p.m., to be delivered by Dr. Ralston Paterson, Miss M. C. Tod, and Professor R. McWhirter.

KENT AND CANTERBURY HOSPITAL, Canterbury.—April 29, 5 p.m. to 7 p.m., clinical meeting.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—April 29, 8 p.m., "Reiter's Disease," by Dr. A. H. Harkness.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—April 29, 5 p.m., "Spondylolisthesis," Hunterian Lecture by Professor R. I. Harris, Professor of Orthopaedic Surgery in the University of Toronto.

ROYAL INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gordon Square, London, W.C., April 29, 5.15 p.m., "The Relevance of Psychological Research to Philosophy," by Professor C. D. Broad.

APPOINTMENTS

Mr. J. L. B. Ansell has been appointed Surgeon-Apothecary to his Majesty's Household at Sandringham in succession to Sir Frederic J. Willans, K.C.V.O., deceased.

DONOVAN, W. T., M.B., Ch.B., D.P.H., Medical Officer of Health, Metropolitan Boroughs of Bethnal Green and Poplar.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—*Chest Physician, Peterborough Area:* G. B. Royce, M.B., Ch.B., Medical Superintendent, *Hellesdon Hospital:* F. J. Napier, M.B., B.S., D.P.M., *borough Area:* G. M. Barling, M.B., Ch.B., D.O.M.S., *Peterborough Area:* Norman Kimbell, M.B., Ch.B., M. (nouncement).

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London; W.C.—*House-physicians:* H. G. Dunn, M.B., B.Ch., M.R.C.P., O. D. Fisher, M.B., B.S., M.R.C.P., D.C.H. *House-surgeon:* Mrs. Christine B. A. John, M.B., Ch.B., Assistant Resident Medical Officer (*Tadworth Court*), Joan P. D'Arcy, M.B., B.Ch.

LEES, DAVID HUGH, M.B., Ch.B., F.R.C.S.Ed., M.R.C.O.G., Assistant Surgeon, Jessop Hospital for Women, Sheffield.

LOGAN, DANIEL CRAWFORD, M.B., Ch.B., D.P.H., Medical Officer of Health, Whittlesey, Cambridgeshire.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Halle.—On March 21, 1949, at Sheffield, to Frances and Hugh, a daughter—Elizabeth Anne.

Hulbert.—On April 5, 1949, at West Hill Hospital, Dartford, to Elizabeth, wife of K. F. Hulbert, F.R.C.S., a daughter.

O'Sullivan.—On April 11, 1949, Una (née O'Leary), wife of Dr. J. G. O'Sullivan, Manchester, a daughter.

Pooler.—On April 10, 1949, at Easterholme, Stretton, Derbyshire, to Pamela (née Relton), wife of H. E. Pooler, M.B., D.A., a brother for Rosamund.

Taylor.—On April 11, 1949, in Edinburgh, to Helena (née Lauder Thomson, M.B., Ch.B., D.P.H.), wife of Dr. A. W. O. Taylor, M.R.C.P.Ed., 9, Frognor Road East, Edinburgh, a son.

Whalley.—On March 10, 1949, to Joy (née Brooks), wife of Dr. G. Hamilton Whalley, Newcastle, a son.

DEATHS

Burn.—On April 10, 1949, at Bryansburn House, Bangor, Co. Down, Mrs. Alice M. Burn, M.B., Ch.B.Ed., D.P.H.

Cuthbert.—On April 7, 1949, at a nursing-home, Glasgow, Charles Campbell Cuthbert, M.D., M.B., Ch.B., formerly of 3, Buckingham Terrace, Glasgow, W.2, and his wife Jean Copeland.

Davies.—On April 6, 1949, after a short illness, John Christopher Davies, M.B., B.Ch.

D'Esteire.—On April 12, 1949, at Westwinds, 31, Alley Park, West Dulwich, S.E.21, William Henry Daniel Patrick D'Esteire, M.D., B.S., M.R.C.S., L.R.C.P., aged 79.

Groome.—On April 10, 1949, at Canterbury. Walter Groome, M.B.E., M.B., C.M., aged 81.

Mackay.—On April 12, 1949, at Rockbank, Campbelltown, Argyll, Duncan Matheson Mackay, M.D.Ed., aged 79.

Neill.—On April 9, 1949, at Coonoor, South India, the Rev. Charles Neill, M.A. M.B., formerly of Craignav, Co. Down, aged 80.

Sorsby.—On April 6, 1949, at Los Angeles, Maurice Sorsby, M.D., F.R.C.S.Ed.

Wacher.—On April 11, 1949, peacefully after a long illness, Harold Wacher, M.D.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Penicillin-Phthalylsulphathiazole Antagonism

Q.—The National Formulary, 1949, on page 13 states that "there is evidence that it [phthalylsulphathiazole] should not be given with penicillin." Would you please quote the evidence?

A.—Poth, Wise, and Slattery (*Surgery*, 1946, 20, 147) gave phthalylsulphathiazole to six patients and succinyl sulphathiazole to five patients to reduce the coliform organisms in the large bowel. Penicillin was then given intramuscularly (20,000 units at two-hourly intervals) while the administration of the sulphonamide was continued. There was no demonstrable effect on the reduced flora induced by succinylsulphathiazole, but there was an abrupt and significant increase in the coliform flora in all the cases treated with phthalylsulphathiazole. The phenomenon could not be explained. The authors recommend that penicillin should not be administered simultaneously with phthalylsulphathiazole if it is important to maintain a reduction in the coliform flora of the bowel, as in the treatment of chronic coliform infections of the urinary tract or ulcerative colitis.

Streicher (*J. Amer. med. Ass.*, 1947, 134, 339) in an investigation on the effect of orally administered penicillin in chronic ulcerative colitis found that the antibacterial effect of penicillin was impeded by the administration of phthalylsulphathiazole. The organisms studied were *Bacterium coli*, *Staphylococcus albus*, and streptococci of gamma type. When 3 g. of phthalylsulphathiazole was given in addition to 225,000 units of penicillin by mouth, 300 units of penicillin was needed to inhibit the *Bact. coli* in vitro as compared with 20 units when the penicillin was given alone. Nevertheless, Streicher considers that in practice oral penicillin and phthalylsulphathiazole may be combined with advantage. More recently Stewart and Jones (*Ann. trop. Med. Parasit.*, 1948, 42, 33) have studied the effects of combining penicillin and phthalylsulphathiazole in the treatment of experimental amoebic infection in the rat. Both drugs were effective prophylactically, with a possible additive effect. Therapeutically, phthalylsulphathiazole enhanced the action of penicillin without itself having any effect on the established infection.

There is thus no definite confirmation of the observations reported by Poth and his co-workers suggesting that the combined use of penicillin and phthalylsulphathiazole is undesirable in clinical practice, but until further evidence is available succinyl sulphathiazole would appear to be a wiser choice in combined therapy.

Xanthomatous Biliary Cirrhosis

Q.—What are the features of the condition known as "primary biliary xanthomatosis"?

A.—"Primary biliary xanthomatosis" is more often termed "xanthomatous biliary cirrhosis." It is a disorder in which chronic obstructive jaundice and hepato-splenomegaly are associated with cutaneous xanthomata (plana or tuberosa), and less frequently with xanthomata in the tendons, bones, or coronary arteries. The serum cholesterol level is greatly raised, owing mainly to an increase in the quantity of cholesterol ester. This uncommon condition is placed by Thannhauser in the group of hypercholesterolaemic primary essential xanthomatoses. This author's monograph (*Lipidoses: Diseases of the Cellular Lipid Metabolism*, 1940, Oxford University Press) contains a full bibliography and should be consulted.

Petroleum Products and the Skin

Q.—Can you give any information on the reactions which may occur when one of the following is applied to the skin: (a) light liquid paraffin, (b) liquid paraffin B.P., and (c) soft paraffin (yellow or white)?

A.—Light liquid paraffin, liquid paraffin B.P., and soft paraffin (yellow or white) do not usually give rise to any

Safe, effective bacteriostasis with

⁶SULFEX⁹

in nasal and sinus infections

The intranasal use of 'Sulfex' ensures prolonged local bacteriostasis and prompt vasoconstriction. The microcrystalline ('Mickraform') sulphathiazole forms a fine, even 'frosting' over the nasal mucosa, and makes possible the maintenance of high local concentrations with the minimum of systemic absorption. The shrinking action of 'Paredrinex' renders the tissues more accessible to the sulphathiazole and promotes ventilation and drainage. 'Sulfex' is indicated in nasal and sinus infections—particularly those secondary to the common cold—and in sore throat. It is equally suitable for children and adults.

'Sulfex' is an aqueous suspension of microcrystalline ('Mickraform') sulphathiazole, 5%, in an isotonic solution of 'Paredrinex', 1% (pH 5.5 to 6.5). Issued in 1-oz. and 8-oz. bottles.

P.S.3

Why Ribena in Skin Disorders?

Because the beneficial role of vitamin C in maintaining the integrity of the skin has been evidenced by the good results reported from its use in various skin disorders.

Notably, because excellent results are reported with natural vitamin C, in the form of 'Ribena' blackcurrant syrup in specific cases of skin disorder, for example acne rosacea, allergic skin manifestations, and even psoriasis. Cases of dry skin and flexural eczema, too, in a large group of school children cleared up rapidly when their dietary was supplemented with Ribena. More specific information will be gladly supplied on request.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

Ribena BLACKCURRANT SYRUP

The Royal Forest Factory, Coleford, Glos.

Enquiries should be addressed to Proprietaries (Eire) Ltd.,
17/22, Princes Street, Dublin

Hepolon is produced by special processes which conserve all the known hæmatopoietic principles of the whole liver. It approximates to the extract described by Gämslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anaemia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the hæmatinic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

Ampones of 2 c.c.; box of 6, 6, and box of 12, 11 5, and box of 24, 22 5.
Rubber-capped vial of 10 c.c., 5, and of 30 c.c., 12 5.

HEPOLON

Contains in 100 c.c. the total soluble extractive matter of 250 g. fresh liver.

THE INTRAVAGINAL TAMPON
IN MENSTRUAL HYGIENE

An important clinical study

*Significant facts
obtained by the close
observation of 25 parous
and nonparous women*

In view of the increasing use of the intravaginal tampon for the absorption of the menstrual flow, the following important study was undertaken to determine whether or not this method of sanitary control is safe and not prejudicial to health.

Twenty-five women—parous and nonparous—were selected and were under daily institutional observation during two successive catamenial periods. Ranging in age from twenty-one to forty-five, some had previously used tampons, others had not.

The following summary indicates clearly the findings of the study.

1. In not a single instance was there any evidence of local irritation brought about by the use of the tampons.
2. No uterine cramps, suggestive of block of the uterine flow or damming back into the tubes were reported in any case of this series.
3. No bladder irritation was reported.
4. The average number of tampons used in a period was ten.
5. In cases in which a cervical erosion was present, neither the amount of bleeding nor the character of the erosion was altered by the use of the tampons.
6. There was no appreciable difference in the bacterial flora of the vagina and cervix, as determined by smear and culture, before menstruation and after the use of the tampons during the menstrual period.
7. There was no appreciable difference in the pH of the vaginal or cervical secretions before menstruation and after the use of the tampons during the period.
8. Absolute comfort and complete absorption of the flow was obtained by the proper correlation of the size of the tampon with the length and calibre of the vagina.
9. The evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health.

CRUDE
LIVER
EXTRACT

'CAMPOLON'

(2 U.S.P. units per c.c.)

Trade Mark

In pernicious anaemia this crude liver extract has proved to be both potent and reliable. Administration of "Campolon" is followed by a prompt and satisfying change in the blood picture and a parallel improvement in the patient's general condition.

'CAMPOLON FORTE'

(15 U.S.P. units per c.c.)

A concentrated preparation, this is of especial value in severe cases of pernicious anaemia and in those with neurological symptoms.

Medical literature, giving details of packings, gladly sent on request

reaction when applied to intact skin, even for prolonged periods. These oils collect in the mouths of the hair follicles, and, when their use in association with cosmetics is accompanied by insufficient attention to skin cleansing, aggregates of oil and particulate matter may give rise to mechanical plugging of the follicle opening. The occurrence of follicular hyperkeratosis, comedones, and sometimes pustular eruptions has been recorded following the use of impure paraffin oils in hair oil (*Year Book of Dermatology and Syphilology*, 1946, p. 277) and also as a result of the application of impure petroleum jelly (yellow soft paraffin). It is likely that the hyperkeratotic reaction in such instances is due to the presence of aromatic hydrocarbons which the refining process has failed to remove. This defect should not occur in medicinal preparations. The introduction of even highly refined paraffins into the subcutaneous tissues gives rise to an oleogranuloma, and consequently this must be borne in mind when application of these oils to damaged skin is considered. The ill effects of paraffin oils on damaged or diseased skin are otherwise due to their physical properties. In general it is undesirable to apply paraffin oils to skin which is inflamed or weeping, as they retain the heat, fail to mop up the exudate, and thus render the skin moist and soggy—a condition in which it is especially liable to infection.

Safe Dose of Acetylsalicylic Acid

Q.—What is the largest dose of acetylsalicylic acid that can be taken within twelve hours without endangering health?

A.—The amount of acetylsalicylic acid which can be taken with safety varies for different people. Single doses of 20 g. (300 gr.) have been fatal, and some susceptible persons have had a severe allergic reaction after 0.6 g. (10 gr.). The principal danger is from haemorrhage, owing to a fall in the blood prothrombin level. If this is counteracted by giving menaphthone beforehand it is probably safe to take from 5 to 10 g. (75 to 150 gr.) in 12 hours.

Dyspareunia

Q.—A woman aged 28 has always had severe pain on intercourse. She is normally developed, and no structural abnormality of uterus, ovaries, or parametrium can be felt. Endometrial biopsy also shows no abnormality. The pain can be elicited only by moving the cervix, but is not felt when the uterus is squeezed without being moved. The patient also complains of frequency of micturition, and has had bouts of mild pyrexia. A recent abortion has not altered the pain. Any advice on this problem would be welcome.

A.—Tenderness of the cervix and the production of pain on moving that organ strongly suggest the presence of disease in the cervix or neighbouring tissue. The other clinical features of this case also point to a diagnosis of chronic cervicitis. If this is deep-seated in the glands, and there is no superficial evidence of it, it may be difficult to exclude. The presence or absence of intermenstrual discharge should help. If chronic cervicitis is present, treatment with surgical diathermy or a graduated course of medical diathermy should be tried. Another possibility is endometriosis in the pouch of Douglas or utero-sacral ligaments; even intermittent pyrexia can be associated with this. For this condition another pregnancy should be encouraged, and if it progresses satisfactorily spontaneous retrogression of the endometriosis might occur. In either of the above conditions, if the pain proves intractable, injection of the paracervical ganglia with a local analgesic is sometimes useful. If no organic disease is present the discomfort might be explained by a congenitally short vagina which exposes the vault and the cervix to an unusual degree of trauma during coitus, or by an inherent hypersensitivity of the cervix. There might also be a psychogenic basis leading to aversion to coitus.

Pig as Vector of Ascaris

Q.—Is there a greater risk of human infection with roundworm from vegetables grown in soil containing pig manure as compared with other manures? How long do the ova remain viable in manure, and is there any means of destroying them?

A.—In spite of the fact that the roundworm (*Ascaris suis*) occurring in the pig is morphologically indistinguishable from the roundworm (*Ascaris lumbricoides*) occurring in man, it does not normally develop to maturity in the human host,

although it has been shown that *A. lumbricoides* may reach maturity in the pig if the animal is placed on a vitamin-deficient diet. The pig cannot therefore be regarded as a reservoir for human ascariasis, but it is believed that pigs play a part in the dissemination of eggs of *A. lumbricoides* which have been ingested previously with human faeces. The ova of *Ascaris* commonly remain viable in buried manure for at least a year, although much longer periods have been recorded. During this resting period they are very resistant to chemicals, but may be destroyed by drying, and perish almost immediately if heated to 55° C.

Thickening of Palmar Skin

Q.—An unmarried female aged 49, well developed and active, is greatly distressed by the formation on both palms of a thickened, dry, rough skin with a tendency to crack and fissure. The condition appears to be hyperkeratosis. What is the treatment?

A.—A diagnosis is necessary before suggesting treatment in this case, and cannot be made without more knowledge of the patient's general condition, menstrual history, past medical and dermatological history, and family history. The condition might be psoriasis, lichen simplex, constitutional eczema, lichen planus, or keratoderma climactericum, among other things. A patchy hyperkeratosis of palms and soles is occasionally associated with the climacteric and is responsive to oestrogen therapy. Treatment should be undertaken with care, starting probably with 0.5 mg. of stilboestrol daily. It should not be carried to the point of provoking uterine haemorrhage if the periods have stopped. It would, perhaps, be advisable to submit the case to a dermatologist for clinical review before undertaking treatment.

Intravenous Calcium Chloride and Gluconate

Q.—(a) I understand that intravenous calcium chloride is dangerous to the digitalis-controlled heart. Does this apply to the rapid intravenous injection of calcium gluconate to determine the circulation time? (b) Have fatalities been recorded with this drug, or with ether, saccharin, dehydrocholic acid ("decholin"), or magnesium sulphate? (c) Which is the safest?

A.—(a) There are numerous reports, both clinical and experimental, on the synergic effects of calcium chloride with digitalis; and fatalities have been recorded in animals and in human beings. On the other hand, many observers have used calcium gluconate without any fatal result in large numbers of patients suffering from serious cardiovascular disease which was fully controlled by digitalis (Goldberg, *Amer. J. med. Sci.*, 1936, 192, 36; Baer and Slipakoff, *Amer. Heart J.*, 1938, 16, 29; Berliner, *Amer. J. med. Sci.*, 1936, 191, 117). H. C. Wall (*Amer. Heart J.*, 1939, 18, 228) pointed out that calcium chloride contained three times as much calcium, weight for weight, as calcium gluconate; and in the former ionization was much greater. The rare fatalities in human beings occurred in extremely ill patients with advanced heart disease. In heart failure the blood volume is greatly increased and the circulation time slowed, these factors acting as safety-valves to the sudden rise of calcium concentration in the chambers of the heart, which apparently causes the fatal outcome (McGuigan and Higgins, *J. Lab. clin. Med.*, 1938, 23, 839). These factors, however, also tend to prevent a precise end-point being attained, and in patients with slow circulation time, and taking less than 5 ml. of calcium gluconate, no subjective sensation may be noticed. Thus, to be safe, intravenous calcium should be given slowly, but this would vitiate the result. Bernstein and Simpkins (*Amer. Heart J.*, 1939, 17, 219) showed that magnesium sulphate had none of the dangers incidental to the use of calcium salts, and gave more exact readings at the slower circulation rates.

(b) No fatalities have been reported following the use of saccharin, dehydrocholic acid, or magnesium sulphate. Leinhardt (*J. Amer. med. Ass.*, 1935, 105, 1759) reported a fatality accompanying the injection of 2.5 ml. of 10% ether in saline in a case of bronchial asthma. He doubted whether this was alone the cause of death, but felt that it was a precipitating factor. Hitzig advises against the injection of saccharin and ether into the same vein, because it may give rise to thrombosis and local pain. If the substances are injected outside the vein severe local reactions occur. The only untoward

effects reported after the use of dehydrocholic acid were in allergic or asthmatic patients. K. J. Norman (*Amer. Heart J.*, 1947, 34, 740) mentioned three such cases, in one of which sensitization to the drug itself was acquired.

(c) Dehydrocholic acid, magnesium sulphate, and saccharin are safe, provided allergy is excluded in the case of the first named.

Arcus Senilis

Q.—What significance should be attached to the presence of a well-developed arcus senilis in a man aged 37, with normal blood pressure and without signs or symptoms of cardiovascular disease?

A.—No significance should be attached to this. The writer has under his care one of a family in the members of which a definite arcus senilis develops at about the age of 16 years. The differential diagnosis is from the Kayser-Fleischer ring, which is coloured and is associated with hepatolenticular degeneration (pseudo-sclerosis and Wilson's disease).

Oestrogen Therapy of Menorrhagia

Q.—In the article on sex hormones in therapeutics (*B.M.J.*, Jan. 29, p. 165) it is stated that intensive oestrogen therapy will control heavy and prolonged menstrual bleeding. What would be the most appropriate synthetic drug to use orally, and in what dosage?

A.—The statement was made in reference to so-called functional uterine haemorrhage. Stilboestrol 1 mg., or ethinyl oestradiol 0.05 mg., orally every four hours, might be used. It is emergency treatment in that it controls the bleeding by raising the oestrogen level above the bleeding threshold. There is still the problem of preventing or controlling oestrogen-withdrawal haemorrhage, which is likely to occur when treatment is suspended.

Ptyalism in Pregnancy

Q.—A patient had excessive salivation all through her first pregnancy; she could not swallow the saliva but had to spit. Belladonna or sedatives failed to relieve the condition. She is now pregnant again and the salivation is returning. What treatment do you suggest?

A.—The treatment of ptyalism in pregnancy is difficult because the aetiology is unknown. There is often, however, as in hyperemesis, a psychological underlay which manifests itself by the constant spitting—a conscious or subconscious dislike or fear of pregnancy. Usually the condition clears up by the time quickening is first felt, and this should be impressed on the patient. Calcium gluconate (10 ml. of 10% solution daily) has been given intravenously with good results in some cases. After a similar query was answered some years ago (April 14, 1945, p. 543) one correspondent advised putting very thin slices of lemon between the cheeks and the teeth. Another reported having successfully treated a patient with 20 drops of 25% benzyl benzoate in 90% alcohol taken in water every four hours.

Treatment of Asthma

Q.—A female patient of 43 has been subject to acute attacks of hay-fever from the age of 8. Six years ago she developed sharp attacks of asthma lasting several days, usually followed by bronchitis. The asthma has been successfully treated with subcutaneous adrenaline. Unfortunately, however, owing to the frequency of nocturnal mild attacks, I have for many months had to use maintenance doses as a suppressive, and in consequence the patient has become adrenaline-fast. She now complains of palpitation and cardiac pain, both during the severe attacks and for some weeks afterwards, despite prolonged rest in bed. A recent blood count showed R.B.C. 3,500,000 and W.B.C. 16,000 per c.mm., with a haemoglobin value of 75%. I am treating the anaemia with intramuscular injections of "anahemin." Can you make any alternative suggestions for prophylaxis of the mild nocturnal attacks, and what treatment do you recommend during the violent attacks?

A.—For the periodic violent attacks, when adrenaline fails, intravenous aminophylline, 0.48 g. in 20 ml., is usually effective. For alternative nightly prophylaxis one might suggest aminophylline 0.2 to 0.4 g. with or without phenobarbitone

gr. 1 (32 mg.); if there is gastric irritation after aminophylline, enteric-coated aminophylline or glucophylline in similar doses might be tried, or the aminophylline could be given per rectum, 0.5 g. in 10 ml. of water, with a syringe and catheter; alternatively, "franol" (theophylline, ephedrine, and phenobarbitone), 1 or 2 tablets, might be tried, and a favourite prescription in such cases is "caffineine" 1 drachm (3.5 ml.) in water thrice a day. This preparation is made up as follows:

R	Caffeine sod. iodid.	5 gr. (0.32 g.)
	Sod. iodid.	5 gr. (0.32 g.)
	Dilute hydriodic acid	5 m. (0.3 ml.)
	Decoction of coffee	40 m. (2.4 ml.)
	Water to	1 fl. dr. (3.5 ml.)

The history and leucocytosis suggest the presence of infection. Is there infection in her sinuses?

Washing-soda in Tea

Q.—A patient who works in a buffet informs me that it is widespread practice to put a handful of washing-soda in a tea urn at each filling to make the tea darker than the strength of the brew would warrant. Would the constant drinking tea so treated be harmful?

A.—It is not likely that any harm would come of the use of washing-soda in tea. But, as with other methods for making tea go further, the resulting drink is not nearly so good as should be.

NOTES AND COMMENTS

Lactation.—Dr. ARMIN RUTISHAUSER (Dessie, Wollo Provin Ethiopia) writes: In a question about lactation in virgins ("Any Questions?" Nov. 20, 1948, p. 925) it is stated that Margaret Me describes how one of the savage tribes in New Guinea adopts babies who are then breast-fed by women who have never had children of their own. Before the war I spent two years at the hospital Dr. Albert Schweitzer, French Equatorial Africa, where I saw following two cases in the obstetrical department. There was a woman who gave birth to a child, but after a few days breast-feeding was impossible, as the breast did not produce any milk, though the baby suckled. All the treatment we undertook had negative results. Then I was asked permission to take mother and child away as the family wanted to consult a sorcerer. I agreed, seeing that we were at a standstill. After some weeks the family came back with the baby all right and mother producing a lot of milk. Another mother died, and her mother, a very old-looking woman with breasts like paper, started to feed the baby after having disappeared for a short time in the jungle. After those experiences my curiosity was aroused and I found out that the women underwent treatment with a result that inactive breasts started to produce milk. During the following year we tried hard to find out what kind of plants were used for this special treatment, but it was quite impossible to get information, as the sorcerers are very anxious to keep their knowledge for themselves. In any case, it would be very interesting to learn more of all the drugs used in Africa, as I am quite sure that there are a great number of very important ones.

Late Menopause.—Dr. HILDA M. DENHOLM-YOUNG (Farningham Kent) writes: Regarding menstruation at age 56 ("Any Questions?" April 2, p. 602), the question does not state if the woman was from Shetland or Orkney, where menstruation finishes normally at about 60 and where children are sometimes borne at that age.

Disclaimer.—Mr. HAROLD DODD (London, W.1) writes: During the past week there have been several announcements in the press with regard to my connexion with the Fife-Openshaw Nursing Home. These have been made in spite of my urgent requests. I begged the Press to confine their statement to the announcement made by Princess Arthur "that she was giving up her connexion with it." My wishes were ignored. Therefore I should be grateful if you would kindly insert this disclaimer.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 23 1949

THE SECRETARY REPORTS

MEETING WITH THE MINISTRY

Representatives of the General Medical Services Committee, headed by Dr. Wand, met representatives of the Ministry of Health on Thursday, April 14, to discuss the case for increased remuneration for general practitioners conveyed to the Ministry on March 4. The Ministry's reply amounted in effect to a refusal to discuss the case until their inquiry now being conducted into the public moneys actually paid to general practitioners for the first nine months of the Service is completed. A full report has been made to the General Medical Services Committee, which met on Thursday, April 21, and a report of the proceedings of that committee will be found in these columns next week.

But, as if by a side wind, another issue arose during the discussion. On being asked whether, in the event of an application being made by the General Medical Services Committee, the question of general-practitioner remuneration could be raised through Whitley machinery and in the event of disagreement recourse had to arbitration, the Secretary of the Ministry of Health stated that "it must not be assumed without further discussion that participation in the Whitley machinery necessarily involves, in the event of disagreement, the right to resort compulsorily to arbitration on all subjects." On being asked to say whether on the subject of remuneration the profession's representatives on the Whitley body could secure arbitration on request, he replied to the same effect, that this must not be assumed. Thus it appears that on what is a crucial issue for the medical profession the Government is proposing to go back on an assurance.

Some evidence of the Government's assurances on this point is given below.

1. During the Second Reading Debate on the National Health Service Bill on Thursday, May 2, 1946, Mr. Greenwood (Lord Privy Seal), replying to the debate on behalf of the Government, said:

"Some references have been made to the conditions of service, remuneration, and so on. As Hon. Members will be aware, the Bill gives the Minister a general power to prescribe by regulations the conditions of service, remuneration, and qualifications of officers and servants employed by the new regional hospital boards or other bodies providing health services under the Bill. It is my right Hon. Friend's intention before prescribing any terms of service or rates of remuneration to use the familiar machinery of discussion and negotiation with employees. Where suitable machinery exists and is in operation it will be used with such adaptations as may be necessary in the new circumstances. What my right Hon. Friend has in mind where there is no machinery is to set up some machinery of the Whitley Council type behind which there may be provision for agreed reference to arbitration should the Whitley Council not be able to carry it out. I think that principle will run all through my Rt. Hon. Friend's administration of this great new Service."

2. On May 25, 1948, when at a meeting between the Minister of Health and representatives of the profession the Minister was asked whether it would be open to the profession immediately after the inception of the Service to raise through Whitley machinery the question of betterment, the Minister replied in the affirmative.

3. In the Government's proposals for Whitley machinery conveyed to the Association in October, 1947, the following paragraphs appear:

DISAGREEMENTS

It is necessary to prescribe the courses available where disagreement arises in any part of the Whitley machine.

(a)

(b) *Functional Council and Central Council.*—It is not possible to give a simple prescription and it is suggested that one of the first duties of the Central Council should be to draw up an agreement defining the field of arbitration. It will suffice here to say that, while the Government hopes that the normal working of Whitleyism will minimize the necessity for arbitration, it is anxious to accord the fullest rights to arbitration subject to the preservation of the Government's prerogatives. A code of conduct is unlikely to be arbitrable, but a simple proposal for a change in wage or salary rates almost certainly is. The necessary machinery can be provided readily by the Ministry of Labour and National Service under the Industrial Courts Act, 1919.

ARBITRATION

Every effort shall be made to accommodate differences of opinion between the two Sides of the Council in order to reach an agreed decision. Where it is impossible to accomplish this, it shall be open to the employers or the staff organizations concerned to seek arbitration in accordance with the terms of an arbitration agreement. In such cases, the matter should be referred to the Minister of Labour and National Service for action under the Industrial Courts Act.

4. In the revised proposals conveyed to the Association in March, 1948, the substance of the last paragraph quoted above was repeated. This paragraph is part of the scheme which has been accepted by the profession.

5. Again and again in the last few years representatives of the profession have been assured by the Ministry—Dr. Dain has asked the question on many occasions—that there would be devised permanent conciliation machinery backed by arbitration to avoid the kind of dispute which has characterized National Health Insurance in the past.

Breach of Undertakings

It is true that the Ministry's statement begins with the words "that it must not be assumed" and refers to further discussions, but it is a departure from a position hitherto maintained and promises given by Ministers and officials. To withdraw the promise of automatic arbitration in the event of disagreement on matters of remuneration would be a breach of many undertakings, a departure from modern negotiating practice, and potentially dangerous to the profession.

Why has this change of front occurred? Clearly, the associations of local authorities have hitherto understood the meaning of the Minister's assurances in terms of compulsory arbitration. We are in good company in the interpretation of the Government's promise on this point. But is the change of front the first sign of an attempt by the Ministry to get the associations of local authorities out of their present difficulty? Clearly an issue of great importance arises.

National Health Service

LABOUR POLICY

When the annual conference of the Labour Party meets at Whitsun it will have before it a pamphlet published by the Party last week entitled *Labour Believes in Britain*. The election programme will be drawn up in the light of the conference's discussions, and before the end of next year the electorate will have an opportunity of deciding whether Britain believes in Labour.

The pamphlet states that as soon as circumstances permit an industrial health service will be set up to "key in" with the National Health Service.

"Some industrial firms have made a praiseworthy start, but over much of industry (including not only factories but offices, warehouses, shops, marshalling yards, and the rest) health standards are far too low. Non-medical factory inspectors and doctors must work hand in hand to achieve a steady improvement in working conditions. Experiments in local organization should be encouraged. As sickness and accident rates fall there will be gain not only in individual health but in production. All who manage industry, whether socialized or private, must place healthy working conditions in the forefront of their plans."

The programme includes the steady development of every part of the National Health Service, including the building of health centres. Enough hospital beds must be provided in properly equipped buildings, and health education of the general public must be extended. "Training of those who wish to enter the medical professions must be brought within the reach of all who can benefit from it, regardless of their incomes. As with the rest of university education, at least three-quarters of the places in the medical schools should be scholarship places."

The Party pats itself on the back again for the lowered infant and maternal mortality. Some of the "first victories of peace," under the Party's four years of rule, are: "Fair shares of necessities. The people, and especially the children, healthier than ever. Record low figures for infant and maternal mortality." The list ends with the piquant statement: "Our new National Health Service is the envy of the world."

COMPENSATION

No claims for the assessment of compensation, submitted for the first time, and received by the Ministry after April 30, will be considered. Applications for advanced payment on grounds of hardship may be made at any time.

ADVISORY APPOINTMENTS COMMITTEES FEES REDUCED

Members of advisory appointments committees set up under Section 14 of the N.H.S. Act, 1946, will in future be paid 4 guineas for work lasting about half a day instead of the 7 guineas that used to be paid for work lasting a day or less. If the work takes less than an hour or so no payment is to be made. The change has been made because the Ministry of Health has found that the work of a committee rarely exceeds half a day. Members of regional boards or of hospital management committees serving on advisory appointments committees are not debarred from being paid at these rates.

ASSISTANTS DOING OBSTETRICS

Executive councils are empowered by the N.H.S. (General Medical and Pharmaceutical Services) Amending Regulations, 1949, as an exception to permit a practitioner providing maternity medical services to employ for those services a deputy or assistant whose obstetric experience has not been approved by the local obstetric committee. The Ministry of Health states that permission should not be given if it is reasonably practicable for a doctor to use a deputy or assistant whose experience has been approved by the committee.

HOSPITAL BOARD APPOINTMENTS

The following are the medical men appointed to fill the vacancies caused by the retirement in rotation of one-third of the members of the fourteen regional hospital boards in England and Wales. They hold the office until March 31, 1952.

Newcastle Regional Hospital Board.—Reappointed: Mr. D. C. Dickson, Dr. W. Fraser.

Leeds Regional Hospital Board.—Reappointed: Dr. D. C. Muir, Professor M. J. Stewart. New member: Dr. W. W. A. Kelly.

Sheffield Regional Hospital Board.—Reappointed: Dr. J. W. Brown, Dr. J. G. McCrie.

East Anglian Regional Hospital Board.—Reappointed: Dr. J. V. Morris.

North-West Metropolitan Regional Hospital Board.—Reappointed: Mr. A. C. Morson, Dr. H. Joules, Dr. H. E. A. Boldero.

North-East Metropolitan Regional Hospital Board.—Reappointed: Mr. Somerville Hastings, M.P.

South-East Metropolitan Regional Hospital Board.—Reappointed: Mr. J. R. H. Turton. New member: Mr. H. C. Edwards.

South-West Metropolitan Regional Hospital Board.—Reappointed: Mr. P. H. Mitchiner, Mr. J. M. Wyatt.

Oxford Regional Hospital Board.—Reappointed: Professor A. D. Gardner, Dr. J. S. Skottowe.

South-Western Regional Hospital Board.—Reappointed: Mr. A. L. Candler, Dr. R. E. Hemphill, Dr. S. McClements. New member: Mr. N. L. Capener.

Welsh Regional Hospital Board.—Reappointed: Mr. R. D. Aiyar, Mr. A. H. Coleman, Dr. H. G. Davies.

Birmingham Regional Hospital Board.—Reappointed: Mr. N. Duggan, Professor H. F. Humphreys, Professor Sir Leonard Parsons, F.R.S., Dr. J. J. O'Reilly.

Manchester Regional Hospital Board.—Reappointed: Dr. W. Briggs. New member: Professor W. F. C. Morris.

Liverpool Regional Hospital Board.—Reappointed: Dr. D. Brown, Dr. J. F. Mountford, Mr. D. R. Owen, Professor H. H. Stones.

AUSTRALIAN HEALTH SERVICE

Since the Australian Pharmaceutical Benefits Act was passed in June, 1948, providing free medicines for patients prescribed on a special form, the B.M.A. in Australia has consistently objected to the limited number of medicaments and appliances that may be prescribed in accordance with the formulary. *The Times* (April 13) reports that the B.M.A. and the Government are unlikely to compromise on the issue, and that the B.M.A. has decided to test the constitutional validity of the measure in the High Court. The Minister for Health and Social Services, Mr. McKenna, has stated that since the Act came into force only 117 doctors have prescribed free medicine, and nearly 6,000 have declined to do so.

MEDICAL FILMS

The Film Committee of the Association is anxious to obtain news of medical films that are planned or in the course of production. A number of interesting films have been produced from time to time by practitioners who are authorities on particular subjects. These films are often shown at scientific meetings during the course of a lecture by the author, but with suitable commentary and captions they could be used on other occasions. Sometimes they are the property of particular medical schools and are used in the course of routine lectures. Often, for reasons of expense, only one copy of the film is made, and this copy deteriorates rapidly with frequent projection. Commercial and scientific firms who produce films usually prepare a master copy from which any number of copies can be made. The master copy is never used except for the purpose of taking prints. Failure to adopt this policy has resulted in the loss of motion-picture material, and the Association wishes to bring to the notice of members and others who intend to produce films at any time that it is anxious to give advice and help on the production of films and the provision of copies.

Any information or inquiries in this connexion or any requests for assistance should be addressed to the Secretary of the Association.

Medical Ethics

Eye Testing at Factories

The Central Ethical Committee has considered the practice in some industrial concerns of having the services of an ophthalmologist at a factory at stated times and of notifying the employees that his services are available for eye testing. In some cases Forms O.S.C.1 are being signed by the industrial medical officer. The committee has expressed disapproval of such arrangements when they do not safeguard the general practitioner's recognized custom of referring his patients to the specialist of his own choice, and when they tend to operate to the exclusion of other ophthalmic practitioners in the area.

HEARD AT HEADQUARTERS

Test Case?

Anyone who has studied the various opinions of learned counsel taken by the Association on the question of medical trade unionism will have discovered how complicated the whole issue is, and indeed how much depends on the interpretation that the courts might give to a few words such as 'workmen, masters, and trade. The Medical Practitioners' Union, which is a properly registered trade union and claims the full protection of the Trade Disputes Act, 1906, has also taken counsel's opinion recently. Their counsel met the Association's to discuss the problem, but they could not reach agreement. Commenting on this deadlock, the *Medical World* of April 1 hints of further action, saying, "The Medical Practitioners' Union remains unshaken in its certainty of a sure legal foundation, but it will now have to take the necessary steps to make this certainty manifest to the profession." These words seem to suggest that the M.P.U. will bring a test case of some kind in the courts.

Fit for What?

It is a far cry from the lowing of cattle on primeval plains to our administrators' utterances, but these still bear traces of their ancestry. The emotional and ambiguous connotations of words make it difficult to phrase instructions precisely, and the regulations that so voluminously govern the activities of N.H.S. doctors are labyrinths of saving clauses designed to exclude all meanings but one. Precision of this kind, which is usually achieved only at the expense of clarity, is out of place in letters—a point made by Sir Ernest Gowers in his admirable book *Plain Words*. Imitation "legalese" is far more annoying to read than the genuine article, yet it abounds in letters running on administrative errands throughout the health service. A correspondent tells us that a regional hospital board sent him a letter asking him to certify that the candidate for a job "is free from any physical defect or disease which now impairs her capacity satisfactorily to undertake the duties of the post for which she is a candidate." The writer of the letter apparently quoted this curious phrase from another document, presumably because he felt that he would be sailing across an uncharted sea if he asked our correspondent to certify that the candidate was fit for the job.

Up to Capacity

The proposed increase in the size of the Council, as a result of bringing in a larger number of directly elected members, the increase not being quite offset by the decrease in other categories, will tax the seating capacity of the council chamber at Headquarters to the full. At present the chamber seats 64 members, with four others—the Chairman, the President, the Chairman of the Representative Body, and the Treasurer—on the dais, but seats have also to be provided for officials. If the recommendations are approved the new Council will be almost equal in number—within two or three—to the first Council of the Association when it was founded in 1832. That Council numbered 70 members. It was widely drawn from all parts of the country, including Edinburgh and Norwich and Swansea. Each member of Council then represented between four and five members of the Association. Each member of the present Council represents between 800 and 900.

Questions Answered

Services without Charge

Q.—(1) Patients frequently ask for smallpox vaccinations and T.A.B. injections as required by shipping companies before they go on pleasure cruises. These people are not "patients" because they are perfectly healthy.

(2) Patients ask for advice and prescriptions on birth control, mostly in cases where the delaying of conception has nothing to do with their health but is prompted by other considerations. They not only require to be fitted with caps, they also require repeatedly prescriptions of chemicals.

(3) Patients are found to need some sort of physiotherapy—e.g., diathermy or ultra-violet light. The doctor has the appliances on his premises. He cannot for 3d. a week treat these cases as part of the N.H.S., though he may be willing to do this for a small fee.

In which of these cases is a fee chargeable?

A.—(1) With very few exceptions—namely, those quoted in paragraph 10 of the First Schedule of the General Medical and Pharmaceutical Services Regulations—a doctor may not demand a fee from one of his public patients. Thus a practitioner will be required to carry out vaccination and T.A.B. injections on one of his public patients without further charge. He can demand a fee if the patient is not included on his public list.

(2) At present it appears that practitioners are expected to give advice and prescriptions on birth control, both for medical and sociological reasons, without charging an additional fee. Representations have been made to the Ministry on this point, and the matter is now under consideration.

(3) At present a practitioner willing to undertake diathermy or ultra-violet therapy on one of his public patients must do so without any additional fee. Representations have been made to the Ministry on this point, and the matter is still under consideration.

Compensation

Q.—The Ministry of Health has notified me that "your claim for compensation under Section 36 of the National Health Service Act, 1946, has been duly considered and the amount of the annual value of the goodwill of your practice for the purpose of calculating compensation has been determined at £2,279." The amount £2,279 represents the average gross receipts for the last three years. Would you please advise me if there are any grounds on which I am entitled to claim any increase on this figure?

A.—The annual loss is the value of the practice at one year's purchase and is arrived at by taking the average gross receipts for the last two accounting years. This was the usual method of valuing a practice for sale. The actual amount of compensation payable will be a multiple of this sum, but the factor to be applied cannot be determined until the aggregate of all claims is known.

Salary for Trainee Assistant

Q.—What salary is payable by the principal to his trainee assistant, if the salary paid is exactly the amount of the grant payable to the principal under the trainee assistant scheme?

A.—The financial arrangements for the trainee assistant scheme provide for the salary and boarding expenses of the trainee together not exceeding £750 p.a. It is envisaged that in some circumstances it might not be appropriate for the maximum permitted remuneration to be paid. Where the full salary of £750 is paid the example shown in the Supplement of Oct. 30, 1948 (p. 149), should be amended as follows:

(a) Assistant's salary	£600
(b) Board and lodging	£100
(c) Additional car	£150
Total	£850
Less	
(d) Employer's superannuation contribution	£56
(e) Employer's National Insurance contribution	£10 8s
(f) Trainee's contribution to superannuation (6%)	£42
Net total	£741 12s
	or £61 16s.
	per month

The Royal Baths, Harrogate

HARROGATE AND ITS ENVIRONS

BY

T. G. REAH, M.D., M.R.C.P.

"There is nothing in our profession of Physicke more usefull, nor in the workes of nature more admirable, than naturall baths and mineral waters."—(E. Jorden, 1569-1632.)

Since the sixteenth century, when William Slingsby advocated the use of its iron-containing waters, Harrogate has been recognized as a health resort, and until quite recent years its reputation depended mainly upon the internal and external application of its waters. They rise in natural springs, of which there are more than 80.

While success was claimed in the past in the treatment of numerous and diverse diseases, the limitations of the uses of mineral waters have been increasingly recognized in recent years, and new methods of treatment and modifications or elaborations of the older treatments have been introduced as they have become available. A large and well-equipped establishment, the Royal Baths, has been erected by the Harrogate Corporation, at a cost of nearly a quarter of a million pounds, in which the various treatments are given, and in 1939 an extensive new wing costing £80,000 was opened in order to relieve the congestion in the main building and to create more comfortable and convenient surroundings for patients. A wide range of hydrological, electrical, and accessory forms of treatment are thus available for the benefit of patients and in particular for those suffering from the chronic rheumatic disorders.

The Royal Bath Hospital, founded in 1824 and rebuilt in 1889, has 150 beds devoted to the care and treatment of patients suffering from rheumatism. Considerable alterations and extensions are now being made at the hospital, and it is hoped in time to provide accommodation for the long-term treatment of patients confined mainly or entirely to bed. A Rheumatism Research Department has been established, and it is

intended shortly to increase the accommodation for the treatment of ambulatory patients and to make increasing use of the facilities at the Royal Baths for the treatment of patients under the National Health Service Act.

The Harrogate and District General Hospital, with 250 beds, provides for the general medical needs of the town and surrounding district, and there are also in the town a home for patients suffering from incurable diseases and several convalescent homes.

The town itself is situated half-way between London and Edinburgh, at about 400 ft. above sea-level, on the edge of the Yorkshire Moors. There are over 350 acres of open spaces, of which the most remarkable is the Stray, an expanse of 200 acres in the centre of the town, which originally was part of the old Forest of Knaresborough and is now preserved for all time by Act of Parliament. From the top of the Observatory Tower on Harlow Hill, at a height of nearly 700 ft. above sea-level, there can be seen on a clear day the Rivers Humber and Tees, York, Ripon, a score of other towns, and numerous castles, abbeys, and parks.

The town is also a centre unique in the number of places of historic and scenic interest to which it leads. Three miles away is Knaresborough, rising from the precipitous banks of the River Nidd and crowned by its fourteenth-century castle. It was to Knaresborough that Constable de Moreville fled in 1170 after the murder of Thomas à Becket, and Richard II was imprisoned there in 1399—tradition says in the room now known as the King's Chamber—before his death a year later at Pontefract.

St. Robert the Hermit and Mother Shipton with her uncanny prophecies will always be associated with the town, and Thomas Hood has told the grim story of Eugene Aram, who was executed 14 years after his murder of Daniel Clarke. The Dropping Well, a petrifying spring, is one of the town's natural curiosities; the water runs over an overhanging ledge into a

Valley Gardens, Harrogate

rock bowl below, and its lime content impregnates the various articles which have been suspended in it, converting them apparently into stone.

Ripley, once an important market-town, is a pleasant village three miles to the north of Harrogate, and still has a market cross and stocks. The castle, with its Cromwellian associations, is the home of Sir William and Lady Ingilby, who have kindly consented to welcome those who join the excursions to Ripley. The church, believed to have been built about 1400, has several fine monuments to the Ingilby family, including a table tomb bearing the mutilated effigy of Sir Thomas Ingilby (died 1369), the founder of the family. In the churchyard is a rare mediaeval penitents' cross, probably about 700 years old.

The City of Ripon, 11 miles from Harrogate, received its first charter of liberties and privileges as a corporate community in 886, when its chief magistrate was styled "Wake-maan." It is therefore full of historic associations. The cathedral contains a Saxon crypt built about 670, but its main structure was erected between 1154 and 1530 and later restored by Sir Gilbert Scott. The Wakeman's House, in a corner of the market-place, is a quaint thirteenth-century building, formerly the residence of the wakemen (mayors) of Ripon and completely furnished in the style of the sixteenth and seventeenth centuries. St. Anne's Hospital, St. Mary Magdalene Hospital, and Thorpe Prebend House are all of considerable antiquarian interest. Several ancient city customs are still retained, such as the sounding of a horn at the market cross 9 o'clock every evening, a practice that originated before 1088. A civic reception has been arranged by the Mayor for

Fountains Abbey

those visiting the city, and a particular privilege will be the sounding of the horn after the reception.

A short distance from Ripon is Fountains Abbey, unsurpassed in beauty among all the ruins of England and of them all the most completely preserved. Magnificently situated in the wooded valley of the River Skell, the abbey was founded in the early years of the twelfth century by 13 monks from the Benedictine Abbey of St. Mary at York, who obtained permission from the Archbishop of York to live under the stricter rules of the Cistercians. After considerable initial hardships their conditions improved, and the house gradually grew in possessions and in reputation until its suppression in 1539, when

it was surrendered to Henry VIII by its last Abbot, Marmaduke Bradley. The abbey is best approached through the park of Studley Royal, the home of Commander and Lady Doris Vyner, who have kindly agreed to welcome one of the parties of visitors. An avenue of limes and beeches leads to a thirteenth-century bridge and mill with near-by yews which gave the founder monks their first shelter. The Great Tower, built by Abbot Huby in Tudor days, is in the Perpendicular style, and there are considerable remains of the church, with its massive nave pillars. The Chapel of the Nine Altars, the chapter-house, and the refectory were noble buildings, and the cellarium is unique in that in all our ruins there is no range of ancient arches comparable to it.

Adjacent to the abbey is Fountains Hall, a fine example of Jacobean architecture, built by Sir Christopher Proctor in 1611 from stone removed from the old infirmary buildings after

Knaresborough, Yorks

the Dissolution. There is a spacious banqueting hall with a minstrel gallery, a bedroom with a secret panel, rare tapestries, and a huge stone fireplace with a quaint panel depicting the Judgment of Solomon. A museum upstairs contains among its original documents the foundation charter of the abbey.

By gracious permission of H.R.H. the Princess Royal and the Earl of Harewood parties are to visit Harewood Park and Gardens. Above the valley of the Wharfe, in the park of 1,800 acres with its old beeches and 50-acre lake, are a church, founded early in the twelfth century, and a ruined fourteenth-century castle. Of the original church only the bowl of the font remains, and the present building is mainly fifteenth century, but it was restored in the eighteenth century and again by Sir Gilbert Scott.

Templenewsam, the "Templestowe" of *Ivanhoe* and the birthplace of Lord Darnley, husband and cousin of Mary Queen of Scots, is now used as an art gallery and museum by the City of Leeds. Its portraits, oak panelling, carved and gilded furniture, armoury, and ivories are only a few of the treasures housed in this historic building.

The City of York, with its magnificent minster, its Roman wall, and its innumerable museums and buildings of historic interest, is 22 miles from Harrogate. The Lord Mayor has kindly consented to arrange for the civic plate to be shown on one of the excursions to the city and to entertain the party to tea.

By the River Wharfe the ruins of Bolton Abbey have been painted by Turner and have inspired Ruskin and Wordsworth. The nave of the priory church is still used as the parish church, but the rest of the buildings are in ruins. Also in Wharfedale are Appletreewick, as attractive as its name; and Burnsall; both are for ever associated with Sir Walter Craven, the Yorkshire Dick Whittington, who became Lord Mayor of London in 1611.

At Brimham Rocks, 1,000 ft. above sea-level, on a moorland plateau of 60 acres, great rocks have by time and weather been converted into a series of grotesque and striking shapes, of which the largest weighs about 100 tons.

On the site of the ancient Roman city of Isurium now stands the village of Aldborough. In its museum are preserved the antiquities found in the neighbourhood; it is to be visited by the kindness of Lady Lawson Tancerd. The church has a fourteenth-century nave, and its fifteenth-century tower is said to have been built from some of the materials of the Roman city.

Rievaulx Abbey, built in 1130 by a band of Cistercian monks on the banks of the River Rye, is unusual in that the alignment of the monastery is north and south instead of east and west, because of the fall of the land. A short distance away, Byland Abbey, another Cistercian foundation, at the foot of the Hambleton Hills, is a very early example of English Gothic. The village of Coxwold in the Vale of Mowbray is also near by, and it was here that Laurence Sterne, vicar of the parish from 1762, wrote the later volumes of *Tristram Shandy* and also *A Sentimental Journey*.

From Harrogate to Wensleydale the road passes through West Tanfield, with its church containing the Marmion tombs, to Middleham, with its Norman castle and its famous racing stables. Charles Kingsley was one of the last of the canons of the collegiate church here. In the neighbouring dale of the River Swale the road passes through lofty moors, steep-sided fells, and grey stone villages to Richmond, whose castle dominates the surrounding country.

The grimness of the West Riding of Yorkshire will be seen on a visit to the Brontë country and the parsonage at Haworth, where this strange family of genius arrived in the spring of 1820. The parsonage, overlooking the bleak churchyard, now belongs to the Brontë Society, and a new wing has been added, but the original rooms are much as when the family lived in them.

One aspect of the industrial life of the West Riding will be seen on a visit arranged for doctors' wives to Listers Mills at Manningham, Bradford. By the kindness of the directors of the firm the whole process in the manufacture of a fabric (velvet) will be seen—the combing of the wool and its carding, spinning, and weaving. Finally there will be a demonstration of the finished products of the firm.

British Medical Association

ONE HUNDRED AND SEVENTEENTH ANNUAL MEETING.

HARROGATE, JUNE 24 TO JULY 1, 1949

President-Elect: C. W. CURTIS BAIN, M.C., D.M., F.R.C.P., Senior Physician, Harrogate General Hospital.

Local General Secretary: D. D. PAYNE, M.D., D.P.H. } B.M.A. Office, Royal Baths, Harrogate.

Executive Officer: G. A. PECK, B.Sc.

Local Science Secretary: J. V. WILSON, M.D., M.R.C.P., Department of Pathology, Harrogate General Hospital.

PROGRAMME

Complete particulars of the programme for the Annual Meeting will be found in the following pages. A longer period is devoted to the scientific meetings, which should prove of exceptional interest. On the social side a very full programme has been drawn up, including numerous excursions to places of interest in the neighbourhood, civic receptions, dances, theatres, concerts, and every kind of sport. It is hoped that the programme so arranged will provide suitable entertainment for visitors and make the meetings successful and enjoyable.

The Annual Representative Meeting will begin at the Royal Hall, Harrogate, on Friday, June 24, at 10 a.m., continuing all day on Saturday and Monday and, if necessary, on Tuesday morning.

The Representatives' Dinner will take place at 7.30 p.m. on Monday, June 27, at the Grand Hotel, and it will be followed at 9 p.m. by the Statutory Annual General Meeting, which will be held in the Ballroom of the Grand Hotel. The adjourned Annual General Meeting and President's

Address will take place in the Royal Hall on Tuesday, June 28, at 8.30 p.m., followed by the President's Reception in the Lounge Hall.

The Annual Dinner of the Association will take place on Thursday, June 30, at 7.30 p.m. in the Majestic Hotel.

The Popular Lecture will be given in the Royal Hall on Friday, July 1, at 8.30 p.m.

The Official Religious Service will be held in St. Peter's Church at 3 p.m. on Tuesday, June 28, and Catholic Benediction will be held in St. Robert's Church at 3 p.m. on Thursday, June 30.

The Reception Room for registration, in the Sun Pavilion, will be opened on Monday, June 27, at 2 p.m. The Ladies' Club will be at the Prospect Hotel.

The Annual Exhibition of Surgical Appliances, Foods, Drugs, and Books will be housed in the Sun Pavilion. The official opening will take place on Tuesday, June 28, at 9 a.m.; it will remain open on June 29 and 30 and July 1 from 9 a.m. to 6 p.m.

The Pathological Museum in the Royal Bath Hospital, Cornwall Road, will be opened on Tuesday, June 28, at 9.30 a.m. and will remain open for the rest of the Meeting. It is hoped to hold a Civic Reception in the Royal Hall on Wednesday evening, June 29.

The local Division is giving a Garden Party open to all members and friends on Thursday, June 30, at 4 o'clock, in the gardens of the *Majestic Hotel*.

The President-Elect has kindly offered to give a sherry party at his house for the Representatives on Thursday evening, June 23.

There will also be a Concert for the Representatives in the Royal Hall on Sunday evening, June 26.

The usual Golf and Chess Competitions will be held.

HOTEL AND LODGING ACCOMMODATION

Harrogate is fortunately placed as regards hotel and other accommodation to suit every requirement. No booking of accommodation for members will be undertaken by the B.M.A. other than for overseas guests. Members intending to be present at the Meeting who have not already booked accommodation are strongly advised to make their arrangements without any further delay, as hotel and boarding-house accommodation is becoming very fully booked up for the period of the conference.

A list of guest and apartment houses can be obtained on application to the Executive Officer, B.M.A. Office, Royal Baths, Harrogate.

To assist members in making their arrangements a list of hotels with accommodation still available is given below. The rates quoted are not guaranteed, but are those published up to date. In order to benefit from the special conference terms, every member should mention when applying that he is attending the B.M.A. Conference.

Name and Address of Hotel	Tel No	Garage	Total No of Guests	Full Board (3 Days or more) per Day	Bed and Breakfast 3 Days (or more)

* Licensed hotels.

NOTE—Ration books are required for visitors to hotels staying more than four nights.

REGULATIONS REGARDING DRESS

Robes with hoods are to be worn at: the Official Religious Service, Tuesday, June 28, at 3 p.m.; the President's Address, Tuesday, June 28, at 8.30 p.m.; the President's Reception, Tuesday, June 28, at 9.30 p.m.; the Mayor's Reception, Wednesday, June 29, at 8.30 p.m.; the Roman Catholic Service, Thursday, June 30, at 3 p.m.

Robes may be hired from Messrs Ede and Ravenscroft, Ltd., 93, Chancery Lane, W.C.2, and should be sent direct to the hotel or other accommodation in which the hirer is resident and not to the Reception Office.

Evening Dress (Tails or Dinner Jacket) with Decorations is to be worn at the President's Reception, Civic Reception, and Annual Dinner. Dress is optional for the Representatives' Dinner.

REGISTRATION FEE AT ANNUAL MEETINGS

The expenditure arising in connexion with the Annual Meetings has in the past been met from a guarantee fund raised by the local profession, supplemented by a grant from the Council of the Association. The Council considers that the time has come when the proportion of the expenses falling upon the local profession should be minimized. With this object in view the Council, while continuing the central grant, has decided that members attending the Annual Meeting (other than members of the Representative Body and overseas visitors) should be asked to pay a fee of one guinea towards the expenses of the meeting. The fee of one guinea will be payable when members register at the Reception Office, Sun Pavilion, Harrogate.

OFFICIAL RELIGIOUS SERVICE

The Official Religious Service will be held in St. Peter's Church, Harrogate, on Tuesday, June 28, and the sermon will be given by His Grace the Archbishop of York. The service will be broadcast in the Northern Programme, and the church is likely to be full. It has therefore been decided to issue tickets for the Procession, for which academic dress is required. It will then be possible to ascertain how many seats will be available for wives and friends. Application for tickets, which will admit to the robing-room at the Royal Hall, can be made on a form which will be enclosed in a future issue of the *Journal*. The tickets themselves will be issued at the Reception Office, Sun Pavilion, from 2 p.m. on Monday, June 27. Members of Council and Representatives will be able to obtain their tickets for robing at the A.R.M. Inquiry Office, Royal Hall, from Friday, June 24. Should the number of members intending to take part in the procession be less than the seating accommodation at the church, additional tickets for admission to the church will be issued on Tuesday morning in order of application. Those receiving them must be in their seats by 2.30 p.m. Those taking part in the procession should reach the Royal Hall by 2 p.m., as all the congregation must be seated before the broadcast begins at 3 p.m.

EXCURSION PROGRAMME

Excursions to places of interest in the neighbourhood of Harrogate are likely to prove a great attraction to the doctors and their wives attending the Annual Meeting. Arrangements for transport and refreshments have already had to be made and the numbers fixed for each excursion. In order to avoid disappointment those wishing to take part in any of the excursions* should therefore fill in the form to be issued shortly and send it, with the appropriate payment, to the Executive Officer, B.M.A. Office, Royal Baths, Harrogate. Yorks. Cheques should be made payable to "The British Medical Association" and crossed.

Applications will be acknowledged at once, but the reserved tickets will be collected at the Reception Office, Sun Pavilion, Harrogate, at any time after 2 p.m. on Monday, June 27, except in the case of Representatives and Members of Council, whose tickets will be issued at the A.R.M. Inquiry Office, Royal Hall, Harrogate, between June 24 and 27.

Tickets for functions other than excursions may not be reserved in advance but will be obtained at the Reception Office at the time of the meeting, as in former years.

*The short morning and evening excursions may also be booked at the time of the meeting at Harrogate.

SCIENTIFIC SECTIONS

The clinical and scientific work will be divided among eighteen Sections, meeting on Tuesday, Wednesday, Thursday, and Friday, June 28, 29, and 30, and July 1.

The Sections will meet in various hotels (see programme).

Below is a list of the names of the Sections and the officers appointed to each, together with provisional programmes.

The following Sections will meet on Four Days:

MEDICINE

President: Professor R. E. TUNBRIDGE, O.B.E., M.Sc., M.D., F.R.C.P. (Leeds).

Vice-Presidents: R. R. BOMFORD, D.M., F.R.C.P. (London); Professor H. W. FULLERTON, M.D., M.R.C.P. (Aberdeen); Professor A. P. THOMSON, M.C., M.D., F.R.C.P. (Birmingham).

Hon. Secretaries: T. G. REAH, M.D., M.R.C.P., 4, Spring Grove, Harrogate; J. L. LOVIBOND, M.D., F.R.C.P., 81, Harley Street, W.1.

Meeting-place: Harrogate Hydro.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion:* Diabetes Mellitus. To be opened by Dr. R. D. LAWRENCE (London), followed by Professor R. E. TUNBRIDGE (Leeds), Insulin and Diet; Mr. H. H. FOURACRE BARNES (London) and Dr. CHARLES ROLLAND (Edinburgh), Pregnancy Aspects; Mr. D. A. HALL, Ph.D. (Leeds), Rapid Blood Sugar Estimations; Dr. R. G. PALEY (Leeds), Skin Complications of Insulin Injections; and Dr. A. J. BALLANTYNE (Glasgow), Ocular Complications.

Wednesday, June 29 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion:* Treatment of Peptic Ulcers. To be introduced and summarized by Sir HENRY COHEN (Liverpool). Opening paper by the late Mr. A. HEDLEY VISICK (York) to be read by Dr. C. N. PULVERTAFT (York), followed by Dr. RICHARD DOLL (London), Sociological Aspects; and Mr. A. D. BEATTIE (Leicester), Surgical Aspect.

Thursday, June 30.—10 a.m., *Papers:* (1) Radioactive Substances in Clinical Medicine, by Dr. RUSSELL FRASER (London); (2) Anticoagulants, by Professor H. W. FULLERTON (Aberdeen); (3) Streptomycin, by Dr. GEOFFREY MARSHALL (London).

Friday, July 1.—10 a.m., *Discussion:* Cirrhosis of the Liver. To be opened by Professor J. W. MCNEE (Glasgow), followed by Dr. N. H. MARTIN (London), Pathology; Mr. J. E. RICHARDSON (London), Surgical Aspects; and Dr. E. R. CULLINAN (London), Summary.

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration:* The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

OBSTETRICS AND GYNAECOLOGY

President: Professor A. M. CLAYE, M.D., F.R.C.S., F.R.C.O.G. (Leeds).

Vice-Presidents: GLADYS KAY, M.D. (Harrogate); Professor T. N. A. JEFFCOATE, M.D., F.R.C.S.Ed., F.R.C.O.G. (Liverpool); ARNOLD L. WALKER, M.B., F.R.C.S., F.R.C.O.G. (London).

Hon. Secretaries: C. RUTHERFORD MORISON, M.D., M.R.C.O.G., 2, Lancaster Road, Harrogate; Miss JOSEPHINE BARNES, D.M., F.R.C.S., M.R.C.P., M.R.C.O.G., 7, Wimpole Street, W.1.

Meeting-place: Prince of Wales Hotel.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion:* Breech Presentation and its Management. To be opened by Mr. R. NEWTON (Manchester), followed by Mr. C. M. MARSHALL (Liverpool), Mr. B. L. JEAFFRESON (Leeds), and others.

Wednesday, June 29 (Combined Meeting with Section of Radiology).—10 a.m., *Discussion:* The Value of X-ray in Assessing Disproportion. To be opened jointly by Professor CHASSAR MOIR (Oxford) and Dr. J. BLAIR HARTLEY (Manchester), followed by Miss MEAVE KENNY (London) and Dr. S. JOSEPHS (Newcastle-upon-Tyne).

Thursday, June 30 (Combined Meeting with Section of Dermatology).—10 a.m., *Discussion:* Pruritus Vulvae. To be opened by Professor T. N. A. JEFFCOATE (Liverpool) and Dr. G. A. GRANT PETERKIN (Edinburgh), followed by Dr. ELIZABETH HUNT (London).

Friday, July 1.—10 a.m., *Discussion:* Functional Uterine Haemorrhage. To be opened by Mr. V. B. GREEN-ARMYtage (London), followed by Dr. P. M. F. BISHOP (London) and Dr. T. N. MACGREGOR (Edinburgh).

PATHOLOGY AND BACTERIOLOGY

President: Professor R. J. V. PULVERTAFT, M.D., F.R.C.P. (London).

Vice-Presidents: Professor T. F. HEWER, M.D., F.R.C.P. (Bristol); J. G. GREENFIELD, M.D., F.R.C.P. (London); A. H. T. ROBB-SMITH, M.D., M.R.C.P. (Oxford).

Hon. Secretaries: J. V. WILSON, M.D., M.R.C.P., Harrogate General Hospital, Harrogate; Professor H. A. MAGNUS, M.D., Department of Pathology, King's College Hospital, Denmark Hill, S.E.5.

Meeting-place: Grand Hotel.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion:* The Laboratory Diagnosis and Prevention of Whooping-cough. To be opened by Professor R. CRICKSHANK (London), followed by Dr. W. C. COCKBURN (London) and Dr. D. G. EVANS (Manchester).

Wednesday, June 29 (Combined Meeting with Section of Tropical Medicine).—10 a.m., *Discussion:* Fat Metabolism and the Sprue Syndrome. To be opened by Professor A. C. FRAZER (Birmingham), followed by Dr. DOUGLAS BLACK (Manchester), Dr. K. D. KEELE (London), and others.

Thursday, June 30.—10 a.m., *Discussion:* Chemotherapy in the Treatment of Malignant Disease. To be opened by Professor E. C. DODDS (London), followed by Sir STANFORD CADE (London), Professor A. HADDOW (London), and Professor F. DICKENS (London).

Friday, July 1.—(Subjects and speakers to be arranged.)

RADIOLOGY

President: J. L. A. GROUT, F.R.C.S.Ed., D.M.R.E., F.F.R. (Sheffield).

Vice-Presidents: C. G. HITCHCOCK, M.R.C.S., L.R.C.P. (Harrogate); J. ALEX. THOMSON, M.B., Ch.B., D.M.R.E. (Harrogate); Professor BRIAN W. WINDEYER, F.R.C.S.Ed., D.M.R.E., F.F.R. (London).

Hon. Secretaries: C. N. PULVERTAFT, M.B., B.Ch., D.M.R.E., York County Hospital, York; JOHN R. NUTTALL, M.D., F.F.R., D.M.R., Radium Department, General Infirmary, Leeds.

The following programme has been arranged:

Tuesday, June 28. *Meeting-place:* Queen Hotel (Therapeutic Meeting).—10 a.m., *Discussion:* The Scope and Limitation of Radiotherapy. To be opened jointly by Dr. J. S. FULTON (Liverpool) and Dr. CHESTER WILLIAMS (Bradford).

Wednesday, June 29. *Meeting-place:* Prince of Wales Hotel (Combined Meeting with Section of Obstetrics and Gynaecology).—10 a.m., *Discussion:* The Value of X-ray in Assessing Disproportion. To be opened jointly by Professor CHASSAR MOIR (Oxford) and Dr. J. BLAIR HARTLEY (Manchester), followed by Miss MEAVE KENNY (London) and Dr. S. JOSEPHS (Newcastle-upon-Tyne).

Wednesday, June 29. *Meeting-place:* Prince of Wales Hotel (Therapeutic Meeting).—10 a.m., *Discussion:* Radiotherapy in Spondylitis Ankylopoietica and Osteoarthritis. To be opened by Dr. E. L. GWENDOLEN HILTON (London), followed by Dr. MARGARET D. SNELLING (London) and Dr. L. JANET MALLENDER (Leeds).

Thursday, June 30. *Meeting-place:* Majestic Hotel (Combined Meeting with Section of Cardiology).—10 a.m., *Discussion:* Angiocardiography. To be opened jointly by Dr. FRANCES GARDNER (London), Interpretation of Normal Angiocardiograms; of those seen in Cases of Cyanotic Heart Disease, and in Aortitis and Aortic Aneurysm; and Dr. J. WILKIN (Sheffield), Technical Considerations; Demonstration of Angiocardiograms. Followed by Dr. K. D. KEELE (London), Angiocardiograms in Acyanotic Heart Disease; Dr. T. H. HILLS (London), Angiocardiograms in Cyanotic Heart Disease; and Dr. F. JACKSON (London), Present Trends in North American Clinics.

Friday, July 1. *Meeting-place:* Queen Hotel (Diagnostic Meeting).—10 a.m., *Discussion:* Radiology of Joints. To be opened by Dr. E. DUFF GRAY (Manchester), followed by Dr. P. H. WHITAKER (Liverpool) and Dr. J. B. KING (Edinburgh).

SURGERY

President: T. V. PEARCE, M.D., F.R.C.S. (Harrogate).

Vice-Presidents: H. HAMILTON STEWART, F.R.C.S. (Bradford); IAN J. FRASER, D.S.O., O.B.E., F.R.C.S. (Belfast); Sir CECIL P. G. WAKELEY, F.R.C.S., F.R.A.C.S., F.R.S.Ed. (London).

Hon. Secretaries: GORDON N. BAILEY, M.A., M.B., F.R.C.S., 2, Lancaster Road, Harrogate; RODNEY SMITH, M.S., F.R.C.S., 6, Devonshire Place, W.1.

Meeting-places: Majestic Hotel (Tuesday, Thursday, and Friday) and Harrogate Hydro (Wednesday).

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion:* Prostatic Obstruction. To be opened by Mr. H. HAMILTON STEWART (Bradford), followed by Mr. WILSON HEY (Manchester), Mr. ASHTON MILLER (Bristol), and Mr. JOHN SWINNEY (Newcastle-upon-Tyne).

Wednesday, June 29 (Combined Meeting with Section of Medicine).—10 a.m., *Discussion:* Treatment of Peptic Ulcers. To be introduced and summarized by Sir HENRY COHEN (Liverpool). Opening Paper by the late Mr. A. HEDLEY VISICK (York), to be read by Dr. C. N. PULVERTAFT (York), followed by Dr. RICHARD DOLL (London), Sociological Aspects; and Mr. A. D. BEATTIE (Leicester), Surgical Aspect.

Thursday, June 30 (Combined Meeting with Section of Neurology and Psychiatry).—10 a.m., *Discussion:* The Treatment, After-Treatment, and Sequelae of Closed Injuries to the Head. To be opened by Professor NORMAN MCMISH DOTT (Edinburgh), followed by Dr. W. RITCHIE RUSSELL (Oxford), Rehabilitation after Head Injury; and Dr. E. STENGEL (Chichester), Psychiatric Aspects of Head Injury. 2.30 p.m., *Occasional Paper:* The Mechanism of Speech and the Repair of a Cleft Palate, by Mr. MICHAEL OLDFIELD (Leeds), illustrated by coloured film and drawings.

Friday, July 1.—10 a.m., *Discussion:* Pain in the Right Iliac Fossa. To be opened by Dr. A. FULLERTON (Batley), followed by Professor D. CHAMBERLAIN (Leeds), Mr. R. K. BOWES (London), and Mr. G. H. MACNAB (London).

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration:* The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

The following Sections will meet on Two Days:

ANAESTHETICS

President: Professor R. R. MACINTOSH, D.M., F.R.C.S.Ed., D.A. (Oxford).

Vice-Presidents: B. L. S. MURTAGH, M.B., Ch.B., F.F.A.R.C.S., D.A. (Birmingham); H. B. WILSON, M.B., Ch.B., D.P.H., F.F.A.R.C.S., D.A. (Aberdeen); GEOFFREY ORGANE, M.D., F.F.A.R.C.S., D.A. (London).

Hon. Secretaries: W. M. JONES, M.B., B.S., D.A., 4, South Drive, Harrogate; J. ALFRED LEE, M.R.C.S., L.R.C.P., F.F.A.R.C.S., D.A., 73, King's Road, Westcliff-on-Sea.

Meeting-place: Queen Hotel.

The following programme has been arranged:

Wednesday, June 29.—10 a.m., *Discussion:* Post-operative Pulmonary Complications. To be opened jointly by Dr. H. J. V. MORTON (Uxbridge) and Dr. E. M. BUZZARD (Oxford), followed by Mr. DONALD BARLOW (London), Dr. DONALD TEARE (London), and Dr. JOAN MILLAR (Newcastle-upon-Tyne).

Thursday, June 30.—10 a.m., *Discussion:* Dental Anaesthesia. To be opened by Dr. W. S. MCCONNELL (London), followed by Dr. STEPHEN COFFIN (London) and Dr. FRED A. BANNISTER (Chester). 11.15 a.m., *Discussion:* The Use of Continuous Caudal and Peridural Analgesia in Obstetrics, Surgery, and Therapeutics. To be opened by Dr. ROBERT A. HINGSON (Johns Hopkins, Baltimore). (Note.—This discussion may be continued at 2.30 p.m.)

ANATOMY AND PHYSIOLOGY

President: Professor JOHN KIRK, M.B., Ch.B., F.R.C.S.Ed. (London).

Vice-Presidents: Professor A. HEMINGWAY, M.Sc., M.B., Ch.B. (Leeds); Professor FRANCIS DAVIES, M.D. (Sheffield); Professor C. McLAREN WEST, M.C., M.B., B.Ch. (Cardiff).

Hon. Secretaries: E. J. FIELD, M.D., M.S., Department of Anatomy, University of Bristol; R. J. SCOTHORNE, B.Sc., M.B., Ch.B., Anatomy Department, School of Medicine, Leeds, 2.

Note: On Tuesday, June 28, *Physiology* and *Anatomy* will meet as separate Sections, but there will be a united meeting on Wednesday, June 29.

The following programme has been arranged:

Physiology—Tuesday, June 28. Meeting-place: Cairn Hydro. —10 a.m., *Symposium* on the Control of Activity in the Gastro-intestinal Tract. *Speakers:* Professor R. A. GREGORY (Liverpool), Motility of the Small Intestine in Relation to Feeding; Dr. A. A. HARPER (Manchester), The Control of Gastric and Pancreatic Secretion; Dr. R. E. DAVIES (Sheffield), Secretary Mechanisms and Their Control; Dr. J. N. HUNT (London), Studies of Gastric Motility.

Anatomy—Tuesday, June 28. Meeting-place: Prince of Wales Hotel.—10 a.m., *Symposium* on Muscle Structure and Function. *Speakers:* Professor W. E. LE GROS CLARK (Oxford), The Vascularization of Muscle, with Special Reference to Ischaemic Necrosis and Reparative Processes; Dr. R. BARER (Oxford), The Organization of the Muscle Fibre; Dr. R. E. M. BOWDEN (London), Some Aspects of Denervation and Re-innervation of Human Voluntary Muscle; Mr. W. F. FLOYD (London), Clinical Value of Electro-myographic Studies; and Professor W. T. ASTBURY (Leeds), The Muscle as a Molecular Machine.

Wednesday, June 29. Meeting-place: Cairn Hydro.—10 a.m., *Symposium* on the Anatomy and Physiology of the Skin. *Speakers:* Professor H. BARCROFT (London), Factors Regulating Blood Flow in the Skin; Dr. C. A. KEELE (London), The Control of Sweating; Dr. R. E. BILLINGHAM (Birmingham), The Anatomical Basis of Epidermal Pigmentation in Man; and Dr. G. WEDDELL (Oxford), The Pattern of Cutaneous Innervation.

CARDIOLOGY

President: Sir JOHN PARKINSON, M.D., F.R.C.P. (London).

Vice-Presidents: JOHN R. H. TOWERS, M.D., F.R.C.P. (Leeds); Professor J. CRIGHTON BRAMWELL, M.D., F.R.C.P. (Manchester); D. EVAN BEDFORD, M.D., F.R.C.P. (London).

Hon. Secretaries: D. R. CAMERON, M.D., M.R.C.P., 14, Clifton, York; GRAHAM W. HAYWARD, M.D., F.R.C.P., St. Bartholomew's Hospital, E.C.1.

The following programme has been arranged:

Thursday, June 30. Meeting-place: Majestic Hotel (Combined Meeting with Section of Radiology).—10 a.m., *Discussion:* Angiocardiography. To be opened jointly by Dr. FRANCES GARDNER (London), Interpretation of Normal Angiocardiograms; of those seen in Cases of Cyanotic Heart Disease, and in Aortitis and Aortic Aneurysm; and Dr. J. WILKIE (Sheffield), Technical Considerations: Demonstration of Angiocardiograms. Followed by Dr. K. D. KEELE (London), Angiocardiograms in Acyanotic Heart Disease; Dr. T. H. HILLS (London), Angiocardiograms in Cyanotic Heart Disease; and Dr. F. JACKSON (London), Present Trends in North American Clinics.

Friday, July 1. Meeting-place: Majestic Hotel.—10 a.m., Simulation of Heart Disease by Other Conditions. To be opened by Dr. RAE GILCHRIST (Edinburgh), followed by (a) Simulation by Pulmonary Conditions, by Dr. J. CLIFFORD HOYLE (London); (b) Simulation by Gastro-intestinal Conditions, by Dr. S. W. PATTERSON (Ruthin Castle); (c) Simulation by Psychoneuroses, by Dr. WILLIAM PHILLIPS (Cardiff). 12 noon, *Discussion:* The Treatment of Obstinate Heart Failure. To be opened by Dr. D. EVAN BEDFORD (London).

CHILD HEALTH

President: Professor C. W. VENING, M.D., F.R.C.P., D.P.H. (Leeds).

Vice-Presidents: Professor R. S. ILLINGWORTH, M.D., F.R.C.P., D.P.H., D.C.H. (Sheffield); NEWTH, M.B., B.S., D.P.H. (Nottingham); Profes RAIG, M.D., F.R.C.P.Ed., F.R.S.Ed. (Leeds).

Hon. Secretaries: L. J. PROSSER, M.B., Ch.B., 11, Ripon Road, Harrogate; T. COLVER, M.D., 10, Claremont Place, Sheffield, 10.

Meeting-place: Grand Hotel.

The following programme has been arranged:

Wednesday, June 29.—10 a.m., *Discussion*: Common Feeding Difficulties in Infancy. To be opened by Professor R. S. ILLINGWORTH (Sheffield), followed by Dr. FRANCES CHARLOTTE NAISH (York), Dr. STANLEY G. GRAHAM (Glasgow), and Dr. JEAN MACKINTOSH (Birmingham). *Discussion*: Domiciliary Care of the Premature Child. To be opened by Dr. F. J. W. MILLER (Newcastle-upon-Tyne).

Thursday, June 30 (Combined Meeting with Section of Preventive Medicine).—10 a.m., *Discussion*: Behaviour Difficulties in Childhood. To be opened by Dr. MILDRED CREAK (London), followed by Professor C. W. VINING (Leeds), Dr. H. C. CAMERON (London), Dr. A. A. E. NEWTH (Nottingham), and Dr. W. S. MACDONALD (Leeds). 3 p.m., Demonstration of Cases and Radiographs of Tuberculosis in Childhood, at Scotton Banks Sanatorium, by Dr. VINCENT RYAN (Knaresborough).

DERMATOLOGY

President: J. T. INGRAM, M.D., F.R.C.P. (Leeds).

Vice-Presidents: BRIAN F. RUSSELL, M.D., M.R.C.P., D.P.H. (London); P. B. MUMFORD, M.D., F.R.C.P. (Manchester); GEOFFREY HODGSON, M.B.E., M.D. (Cardiff).

Hon. Secretaries: S. T. ANNING, M.D., M.R.C.P., 5a, Shaw Lane, Leeds, 6; H. J. WALLACE, M.D., M.R.C.P., 80, Harley Street, W.1.

The following programme has been arranged:

Thursday, June 30. Meeting-place: Prince of Wales Hotel (Combined Meeting with Section of Obstetrics and Gynaecology).—10 a.m., *Discussion*: Pruritus Vulvae. To be opened by Professor T. N. A. JEFFCOATE (Liverpool) and Dr. G. A. GRANT PETERKIN (Edinburgh), followed by Dr. ELIZABETH HUNT (London).

Friday, July 1. Meeting-place: Majestic Hotel.—10 a.m., *Discussion*: Psoriasis. To be opened by Dr. H. W. BARBER (London), followed by Dr. BRIAN F. RUSSELL (London) and Dr. J. H. TWISTON DAVIES (Manchester). *Occasional Paper*: The Uses and Abuses of Chemotherapy in Dermatology, by Dr. F. F. HELLIER (Leeds). 2.30 p.m., Clinical Meeting at Royal Bath Hospital.

NEUROLOGY AND PSYCHIATRY

President: W. RUSSELL BRAIN, D.M., F.R.C.P. (London).

Vice-Presidents: W. R. HENDERSON, O.B.E., M.B., Ch.B., F.R.C.S. (Leeds); DAVID ROBERTSON, M.D. (York); R. G. GORDON, M.D., F.R.C.P. (Bath).

Hon. Secretaries: JAMES VALENTINE, M.B., Ch.B., D.P.M., Scalebor Park, Burley-in-Wharfedale, near Leeds, Yorks; HELEN E. DIMSDALE, M.D., M.R.C.P., 41, Devonshire Street, Portland Place, London, W.1.

Meeting-place: Majestic Hotel.

The following programme has been arranged:

Wednesday, June 29.—10 a.m., *Discussion*: Intractable Pain. To be opened jointly by Dr. J. PURDON MARTIN (London) and Mr. WYLIE MCKISSOCK (London), followed by Dr. E. B. STRAUSS (London), Psychiatric Aspect; and Dr. ANDREW WILSON (London), Pharmacological Aspect.

Thursday, June 30 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion*: The Treatment, After-Treatment, and Sequelae of Closed Injuries to the Head. To be opened by Professor NORMAN McOMISH DOTT (Edinburgh), followed by Dr. W. RITCHIE RUSSELL (Oxford), Rehabilitation after Head Injury; and Dr. E. STENGEL (Chichester), Psychiatric Aspects of Head Injury.

OCCUPATIONAL HEALTH

President: Professor R. E. LANE, M.D., F.R.C.P. (Manchester).

Vice-Presidents: Professor G. P. CROWDEN, O.B.E., D.Sc., M.R.C.P. (London); F. S. COCKSEY, O.B.E., M.D., D.Phys.M. (London); W. BLOOD, M.R.C.S., L.R.C.P. (London).

Hon. Secretaries: CHARLES CRESDEE, M.R.C.S., Wits End, Fixby Road, Huddersfield; R. S. F. SCHILLING, M.D., D.P.H., Department of Occupational Health, University of Manchester, Manchester, 13.

Meeting-place: Majestic Hotel.

The following programme has been arranged:

Wednesday, June 29.—10 a.m., *Discussion*: The Development of a Comprehensive Medical Service for Industry. To be opened by Dr. DONALD STEWART (Birmingham), followed by Dr. STUART LAIDLAW (Glasgow) and a general practitioner (name to be announced later).

Thursday, June 30.—10 a.m., *Discussion*: Tuberculosis and Occupation. (1) Tuberculosis in the Boot and Shoe Trade by Dr. ALICE STEWART (Harrow-on-the-Hill); (2) Mass Radiography in Industry, by Dr. W. POINTON DICK (Denham); (3) Rehabilitation and Resettlement, by Dr. F. R. G. HEAL (London).

OPHTHALMOLOGY

President: JAMES FISON, M.D. (Harrogate).

Vice-Presidents: JOHN MARSHALL, M.C., M.B., Ch.B., D.O.M.S. (Glasgow); N. P. R. GALLOWAY, M.B., Ch.B., D.O. (Nottingham); A. B. NUTT, M.B., B.S. (Sheffield).

Hon. Secretaries: JANE A. M. SHEPHERD, M.B., Ch.B., D.O.M.S., 39, Harlow Oval, Harrogate; P. D. TREVOR-ROPER, M.B., B.Ch., F.R.C.S., D.O.M.S., 126, Harley Street, W.1.

Meeting-place: Masonic Hall, Harrogate.

The following programme has been arranged:

Thursday, June 30.—10 a.m., *Discussion*: Ophthalmology in Relation to Diseases of the Skin. To be opened by Mr. J. H. DOGGART (London), followed by Dr. ALICE CARLTON (Oxford) and Dr. I. B. SNEDDON (Sheffield). Afternoon, *Occasional Papers*: (1) Scleromalacia Perforans, by Mr. H. V. INGRAM (Newcastle-upon-Tyne); (2) Angiomatosis Retinae, by Mr. A. G. CROSS (London); (3) Watery Eye, by Mr. JOHN MARSHALL (Glasgow).

Friday, July 1.—10 a.m., *Occasional Papers*: (1) Toxoplasmosis, by Mr. A. B. NUTT (Sheffield); (2) Practical Ophthalmology in Spain and Holland in 1948, by Mr. JOHN FOSTER (Leeds).

ORTHOPAEDICS

President: R. BROOMHEAD, M.B., F.R.C.S. (Leeds).

Vice-Presidents: C. GORDON IRWIN, M.B., F.R.C.S. (Edinburgh); H. JACKSON BURROWS, M.D., F.R.C.S. (London); F. W. HOLDSWORTH, M.B., M.Ch. F.R.C.S. (Sheffield).

Hon. Secretaries: IAN LAWSON DICK, M.B., Ch.M., F.R.C.S. (Edinburgh), 2, Walmer Villas, Manningham Lane, Bradford; J. P. CAMPBELL, M.B., Ch.B., F.R.C.S. (Edinburgh), 1, Tavistock Avenue, Mapperley Park, Nottingham.

Meeting-place: Majestic Hotel.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussions*: (1) Closed Fracture of the Shaft of the Radius and Ulna. To be opened by Mr. E. MERVYN EVANS (Birmingham), followed by Mr. F. W. HOLDSWORTH (Sheffield) and Mr. IAN LAWSON DICK (Bradford) 11.30 a.m., (2) Upper Limb Pain due to Lesions of the Thoracic Outlet. To be opened by Professor LAMBERT ROGERS (Cardiff).

Wednesday, June 29 (Combined Meeting with Section of Rheumatology).—10 a.m., (1) The Structure and Functions of the Synovial Membrane, by Professor D. V. DAVIES (London); followed by The Varieties of Pathological Reactions Encountered in Human Synovial Tissues, by Dr. D. H. COLLINS (Leeds); (2) Partial Denervation of the Hip-joint in Osteoarthritis, illustrated by film, by Mr. H. PETTY (Leeds); followed by Indications for Vitallium Mould Arthroplasty of the Hip and Survey of End-results, by Mr. R. BROOMHEAD (Leeds). (3) Physical Treatment of Arthritis. To be opened by Dr. H. F. TURNER (London).

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration*: The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

OTO-RHINO-LARYNGOLOGY

President: A. B. PAVEY SMITH, M.C., M.B., F.R.C.S. (Harrogate).

Vice-Presidents: W. I. DAGGETT, M.B., B.Ch., F.R.C.S. (London); R. GARNETT PASSE, F.R.C.S., D.L.O. (London); GEORGE SEED, M.B., Ch.B., F.R.C.S., D.L.O. (Leeds).

Hon. Secretaries: J. E. REES, M.R.C.S., L.R.C.P., D.L.O., 10, York Place, Harrogate; H. S. SHARP, M.B., B.Ch., F.R.C.S., 149, Harley Street, W.1.

Meeting-place: Cairn Hydro.

The following programme has been arranged:

Thursday, June 30.—10 a.m., *Discussion*: Nasal Allergy. To be opened by Mr. R. R. SIMPSON (Hull), followed by Professor R. B. HUNTER (Dundee), Mr. J. GERRIE (Aberdeen), Dr. N. SOUTHWELL (London), and Dr. H. H. MOLL (Leeds).

Friday, July 1.—10 a.m., *Discussion*: Acute Respiratory Obstruction in Infants and Young Children. To be opened by Mr. G. E. ARCHER (Manchester), followed by Dr. MARY J. WILMERS (London), Mr. J. H. OTTY (Bradford), and Dr. E. C. BENN (Leeds).

PREVENTIVE MEDICINE

President: Professor R. H. PARRY, M.D., F.R.C.P., D.P.H. (Bristol).

Vice-Presidents: D. D. PAYNE, M.D., D.P.H. (Harrogate); C. FRASER BROCKINGTON, M.A., M.D., D.P.H. (Wakefield); R. H. H. JOLLY, M.D., D.P.H. (Wolverhampton).

Hon. Secretaries: HUGH O. M. BRYANT, M.B., Ch.B., D.P.H., Health Department, Municipal Offices, Harrogate; H. J. TRENCHARD, M.B., Ch.B., M.R.C.P., Chest Clinic, 53, Greenhill Crescent, Harrow, Middlesex.

Meeting-place: Grand Hotel.

The following programme has been arranged:

Thursday, June 30 (Combined Meeting with Section of Child Health).—10 a.m., *Discussion*: Behaviour Difficulties in Childhood. To be opened by Dr. MILDRED CREAK (London), followed by Professor C. W. VINING (Leeds), Dr. H. C. CAMERON (London), Dr. A. A. E. NEWTH (Nottingham), and Dr. W. S. MACDONALD (Leeds).

Friday, July 1.—10 a.m., *Discussion*: Marriage and Pregnancy in Relation to Tuberculosis. To be opened by Dr. F. A. H. SIMMONDS (South Mimms), followed by Dr. R. C. COHEN (Baintree) and Dr. JEAN HALLUM (Birmingham). *Occasional Paper*: Recent Developments in Influenza, by Dr. C. H. ANDREWES (Hampstead).

RHEUMATOLOGY

President: W. YEOMAN, M.D. (Harrogate).

Vice-Presidents: G. NORMAN MYERS, M.Sc., M.D., F.R.C.P. (Cambridge); G. D. KERSLEY, M.D., F.R.C.P. (Bath); H. F. TURNER, D.M., M.R.C.P. (London).

Hon. Secretaries: D. N. ROSS, M.D., F.R.F.P.S., Royal Bath Hospital, Harrogate; DORIS M. BAKER, M.D., M.R.C.P., 9, Upper Wimpole Street, W.1.

Meeting-place: Majestic Hotel.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion*: (1) Rheumatoid Arthritis in the Young. To be opened by Dr. B. E. SCHLESINGER (London), followed by Professor W. S. M. CRAIG (Leeds) and Dr. DONALD WILSON (Bognor Regis). (2) *Clinical Lecture-Demonstration*. Speakers not yet settled.

Wednesday, June 29 (Combined Meeting with Section of Orthopaedics).—10 a.m., (1) The Structure and Functions of the Synovial Membrane, by Professor D. V. DAVIES (London); followed by The Varieties of Pathological Reactions Encountered in Human Synovial Tissues, by Dr. D. H. COLLINS (Leeds). (2) Partial Denervation of the Hip-joint in Osteoarthritis, illustrated by film, by Mr. H. PETTY (Leeds); followed by Indications for Vitallium Mould Arthroplasty of the Hip and Survey of End-results, by Mr. R. BROOMHEAD (Leeds). (3) Physical Treatment of Arthritis. To be opened by Dr. H. F. TURNER (London).

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration*: The Role of Surgery in Rheumatism. "Movement is Life" (Lucas Championnière). 4.30 p.m., Report on Proceedings of International Congress of Rheumatology at New York, by Dr. G. D. KERSLEY (Bath) and others.

TROPICAL MEDICINE

President: G. W. M. FENDLAY, C.B.E., M.D., F.R.C.P. (London).

Vice-Presidents: Professor B. G. MAEGRAITH, M.B., B.S., (Liverpool); Colonel H. E. SHORTT, C.I.E., M.D., D.T.M., I.M.S. (Ret.) (London); J. BALFOUR KIRK, C.M.G., F.R.C.P., D.P.H., D.T.M.&H. (London).

Hon. Secretaries: B. CLIVE NICHOLSON, M.D., M.R.C.P., D.P.H., 24, Swan Road, Harrogate; CLEMENT C. CHESTERMAN, O.B.E., M.D., M.R.C.P., D.T.M.&H., 7, Parsifal Road, N.W.6.

Meeting-place: Grand Hotel.

The following programme has been arranged:

Tuesday, June 28.—10 a.m., *Discussion*: Tropical Diseases as Aftermath of War. To be opened by Air Vice-Marshal T. C. ST. C. MORTON (R.A.F.), followed by Dr. A. R. D. ADAMS (Liverpool), Dr. J. P. CAPLAN (London), Sir GORDON COVELL (London), Professor G. J. STEFANOPOULOU (Pasteur Institute, Paris), and Dr. F. HAWKING (London).

Wednesday, June 29 (Combined Meeting with Section of Pathology and Bacteriology).—10 a.m., *Discussion*: Fat Metabolism and the Sprue Syndrome. To be opened by Professor A. C. FRAZER (Birmingham), followed by Dr. DOUGLAS BLACK (Manchester), Dr. K. D. KEELE (London), and others.

TIME-TABLE OF MEETING

Key

R.—events available for members of Representative Body and Ladies accompanying them.

L.—events primarily arranged for Ladies.

U.—events for all Members and Ladies accompanying them.

*—Academic Robes should be worn.

Thursday, June 23

8.00 p.m.—R. "Get-together"—Private Sherry Party—Dr. Bain's house, St. Ann's, York Place.

Friday, June 24

9.00 a.m.—A.R.M. Inquiry Office open—Royal Hall.
9.30 a.m.—Ladies' Club open for registration—Prospect Hall.
10.00 a.m.—Annual Representative Meeting—Royal Hall.
11.00 a.m.—Civic Welcome to Representatives—Royal Hall.
L. Orchestra and coffee—Lounge Hall.
12.30 for 1.00 p.m.—Lunch to Overseas Representatives—Queen Hotel.
2.30 to 5.30 p.m.—L. Coach tours.
5.30 to 6.15 p.m.—Tour of Royal Baths.
8.00 to 10.00 p.m.—R. Coach tours.
R. Bridge.
R. Theatre.

Saturday, June 25

9.00 a.m.—A.R.M. Inquiry Office open—Royal Hall.
9.30 a.m.—Annual Representative Meeting—Royal Hall.
9.30 a.m.—Ladies' Club open—Prospect Hotel.
L. Orchestra and coffee—Lounge Hall.
2.00 to 5.30 p.m.—L. Coach tours.
5.30 to 6.15 p.m.—R. Tour of Royal Baths.
6.00 p.m.—Press Cocktail Party—Fountain Court (Royal Baths).
7.00 for 7.30 p.m.—Glasgow Graduates' Dinner—Majestic Hotel.
8.00 to 10.00 p.m.—R. Coach tours.
R. Dancing.
R. Theatre.
R. Bridge.

Sunday, June 26

R. Church Services.
R. Tour of Royal Baths.
R. Tour of Royal Bath Hospital.
R. Golf.
R. Tennis.
10.30 a.m. to 6.00 p.m.—R. Long coach tours.
2.00 to 5.30 p.m.—R. Short coach tours.
8.00 p.m.—R. Celebrity Concert—Royal Hall.

Monday, June 27

9.00 a.m.—Council Meeting—Council Room, Municipal Offices.
9.00 a.m.—A.R.M. Inquiry Office open—Royal Hall.
9.30 a.m.—Ladies' Club open—Prospect Hotel.
10.00 a.m.—Annual Representative Meeting—Royal Hall.
10.00 a.m. to 12.30 p.m.—L. Coach tours.
10.00 a.m. to 6.00 p.m.—Coach tours.
11.00 a.m.—L. Tour of Royal Baths.
L. Orchestra and coffee—Lounge Hall.
2.00 p.m.—Reception Room open for registration—Sun Pavilion.
2.00 to 5.30 p.m.—L. Coach tours.
5.30 p.m.—L. Tour of Royal Baths.
7.00 for 7.30 p.m.—R. Representatives' Dinner—Grand Hotel.
9.00 p.m.—U. Annual General Meeting—Grand Hotel Ballroom.

Tuesday, June 28

- 9.00 a.m.—Official opening of Exhibition by President—Sun Pavilion.
 9.00 a.m.—Reception room open for registration—Sun Pavilion.
 9.30 a.m.—Ladies' Club open—Prospect Hotel.
 9.30 a.m.—Opening of Pathological Museum—Royal Bath Hospital.
 10.00 a.m.—*Scientific Sections*.
 10.00 a.m. to 12.45 p.m.—L. Coach tours.
 L. Orchestra and coffee—Lounge Hall.
 3.15 p.m.—L. Coach tours.
 3.30 p.m.—U*. Official Religious Service, St. Peter's Church.

 8.30 p.m.—Popular Lecture—Royal Hall.

PROPOSED AMENDMENTS TO COUNCIL'S
REPORT

GENERAL MEDICAL SERVICES

Constitution of General Medical Services Committee

AMENDMENT by Halifax: (1) That the General Medical Services Committee (formerly Insurance Acts Committee) should be reconstituted to form the executive body of all general practitioners grouped within the framework of the B.M.A. in areas conforming to the present B.M.A. Divisional Areas.

(2) That representatives on this executive body should be elected direct by vote of practitioners. Each constituency should conform to the area of each Branch Council area of the B.M.A. The Central Conference may also elect representatives.

(3) That this executive body should be subject to no other body by veto in matters which have been decided by a central conference composed of representatives of the practitioner group.

(4) That this executive body should have direct access to the Minister of Health.

ORGANIZATION

Election of Central Council of the Association

Recommendation of Council: That the number of members to be directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland be increased from 22 to 37.

AMENDMENT by Bury: That the number of members of the Council elected by Branches should not be fewer than 42, and that these 42 or more be distributed among groups according to membership and strength.

AMENDMENT by Bury: That the term of membership of the *ex officio* members of Council be limited to three years.

Correspondence

Midwives and Doctors

SIR.—The letter from Dr. O. E. L. Sampson (*Supplement*, March 26, p. 166) is of extreme importance to the maternity services of this country. I am in a similar position to Dr. Sampson and share his fears.

I read recently an address by Dr. Joan Moignard in *Public Health*, January, 1949, and I think that the following extract from her address is so important that it should receive much wider circulation among the profession.

"The provision of the free services of a doctor should be a great step forward in improving the maternity services, and I am quite certain that anyone who has heard the Minister of Health speak about it will have been convinced that it is a sincere and honest attempt to provide for all women advantages hitherto only available for the better-off sections of the community. And yet it is this provision that has caused most concern to everyone who is anxious about the quality of the service."

"Since July 5 there has been a remarkable eagerness on the part of general practitioners, many of whom previously had shown great reluctance to undertake midwifery, to book maternity cases, and yet they are the people who are complaining of being overworked. One cannot help having a suspicion that the fees for maternity work have a great influence on their actions. I personally have come across a number of cases where an expectant mother had no intention of booking a doctor until at a chance contact the suggestion that she should do so was made by the doctor himself."

"The consequence of this to individual patients, who in all good faith are naturally anxious to avail themselves of what are understandably regarded as the advantages of the new provisions, is a matter for anxiety. The usual course of events seems to be this. The patient is advised to book a midwife to act as a maternity nurse. Antenatal care is undertaken by the doctor, the patient usually waiting in a crowded surgery for a somewhat perfunctory examination, at which regular attendance is not insisted upon. Delivery is undertaken by the midwife, who seems to change her status with amazing frequency, and the doctor may or may not see his patient

again for a post-natal visit, which only too often degenerates into merely a vaginal examination.

"Let us consider antenatal and post-natal care in more detail. Before July 5 this was carried out partly by the midwife visiting the patient at home, and partly at antenatal and post-natal clinics. Here an attempt was made to bring as many as possible of the advantages which maternity hospitals offer their cases to patients having their babies at home. Of these I will mention only a few. Thorough general medical overhaul, routine obstetric examination, blood-pressure and urine examination need no comment. Dental inspection and any necessary treatment is offered by, most clinics, and the Ministry of Health has laid down that expectant and nursing mothers constitute a priority class for this service. Routine W.R., blood grouping, and rhesus investigation are carried out at most clinics, and the advantages of this are obvious. Welfare foods are available at the clinic, which is a saving of precious time and energy to the patient. General advice on the hygiene of pregnancy, diet, rest, exercise, clothing, and the requirements of the baby is given, and appropriate literature provided. It is very doubtful whether it is possible for a service of this sort of completeness to be provided other than by some type of clinic, and I wonder how many doctors' patients are getting it at the moment. It is the sum of all these details, in addition to competent obstetric care, which helps to achieve healthy motherhood.

"The question of competence brings me to two other problems—the status of the midwife and the qualifications of doctors undertaking midwifery. Many of us in recent years have heard a little too much of the professional status of midwives, which has been exaggerated to extremes. But the fact remains that 96% of all confinements are normal, and I question whether anyone is more competent to undertake normal cases than the midwife, who is doing nothing but midwifery and has the time and patience to await events without the thought of a long visiting list and a crowded surgery. One of the reasons for the very good results obtained by midwives is that their work is strictly limited to what they are trained to do, and help must be summoned if these circumstances cease to obtain; but their work must be backed up by good antenatal and post-natal services, and by good obstetrics when help is required. The midwife should be present with the patients at antenatal examinations, have full reports of all investigations and access to record cards, and have opportunities for discussing her patients with the doctor. At present in so many cases the midwife is booked as a maternity nurse, is denied all these facilities, but is left to deliver unaided, not her own, but someone else's patient.

"One of the constant grumbles of midwives for many years has been that when they have needed to summon medical aid the quality of the help received has fallen far below their own standards and those of the antenatal and post-natal care given at a clinic. It was hoped that when panels of general-practitioner obstetricians were formed this would be remedied.

"The Royal College of Obstetricians and Gynaecologists has been considering this problem for a long time, and has repeatedly stated that in its view only suitably qualified doctors should undertake maternity work. To this end it introduced the College's Diploma in Obstetrics—the D.R.C.O.G. This is not in any sense a specialist qualification: it is a diploma awarded on the results of an examination following a period of resident postgraduate training in a maternity hospital recognized by the College, and is intended solely to set a standard for general-practitioner obstetricians. I suggest that the possession of this diploma, which could be acquired with very little effort by anyone who possesses the skill and knowledge he should have to do maternity work, should be required by obstetric committees from those wishing to be included in panels of general-practitioner obstetricians.

"I do not propose to touch on problems of organization and responsibility for services, but I would in conclusion like to put forward a scheme in outline which would meet these points that I have discussed. Assuming that only normal cases come under the domiciliary service, the midwife should be the responsible person in charge of the case. This provides for continuity of care, which from the patient's point of view is a psychological necessity. The midwife's care should be backed up by an antenatal clinic staffed by a doctor qualified to undertake maternity cases. Whether these clinics are provided by the local authority or by groups of practitioners would vary according to local circumstances.

"There is nothing new in this. But there is one principle which needs to be satisfied in a good service, and that is that the person responsible for antenatal care should also be responsible for delivery. I do attach a great deal of importance to this. If no medical aid is needed at delivery, the requirement is fulfilled by the midwife who has participated in the work of the antenatal clinic. But if medical aid is required I suggest that the doctor called should be the same doctor who has attended the patient at the antenatal clinic, and who from that previous contact will inspire more confidence and bring more knowledge than someone seeing the case for the first time. With this type of arrangement adequate numbers of doctors who are suitably qualified would be available, and the quality of care given to each individual case would be greatly improved."

I would add that the position has been aggravated by the profession's opposition to the recognition of the general-practitioner obstetrician, in spite of their lack of opposition to the recognition of the D.A. and D.O.M.S. I would also point out that there is absolutely no encouragement at the moment for any G.P. to undertake to become more proficient at this work, as the fees for his services are those that any G.P. can obtain. In conclusion I am sure that if things remain as they are, the Ministry will have to report a rise in the maternal and infant mortality rates after a year or two of the present unfortunate state of affairs.—I am, etc.,

London, N.2.

G. D. S. BRIGGS.

Display of Hearing-aids

SIR.—Mr. Ian G. Robin's letter (*Supplement*, March 19, p. 157) points the case for a square deal for those manufacturers and distributors of hearing-aids whose standards of business, approved by the National Institute for the Deaf, give them the right, which in nearly all cases they have exercised, to be members of the Hearing-Aid Manufacturers Association. What little Press advertising is done by our members has to conform to our own regulations, made in the interests of the deaf public with the full approval of the National Institute for the Deaf.

The policy of excluding our members' aids from hospital clinics is therefore a restraint upon firms who accept our rigid standards but not on those who do not accept them. It will certainly encourage doorstep sales to the detriment of sales on medical and personal recommendation, on which our members mainly rely. The policy also deprives the doctor of his hitherto fully acknowledged right to prescribe what is best for his patient. The restoration of hospital facilities for our members' aids is therefore in the interests not only of the members themselves but also of the medical profession and the deaf public.—I am, etc.,

R. G. STAPLES.

Secretary, Hearing-Aid Manufacturers Association
and Society of Aural Technicians.

London, N.21.

Anticipate Legislation

SIR.—The following appears in Harvey Cushing's *From a Surgeon's Journal* on p. 373:

"A long pow-wow after dinner on the after-the-war problems of medicine, and the urgent need of formulating plans to meet the new situation which will doubtless arise. All agree that State medicine will come to play an increasingly important role, and the profession must anticipate legislation by formulating it themselves rather than having this done by politicians and lawyers."

The date is June, 1918, and the place Boulogne.—I am, etc.,

London, W.1

HENRY MACCORMAC.

Plea for Moderate Lists

SIR.—Dr. J. W. O. Holmes's letter (*Supplement*, March 26, p. 164) condemning the tapering capitation fee is so well argued that I feel I must attempt a reply in favour of the more moderate numbers. There are some cases which, there would be general agreement, G.P.s should cope with unaided; there are others which it is their plain duty to send to hospital; but there is a large group in which there can be no general agreement because of the personal factor.

Let us consider a keen man aged 30 with some 2,000 patients. He does a little minor surgery, attempts some common-sense psychological medicine, and keeps at home those seriously ill patients whom he believes likely to do best at home. Perhaps he also occasionally manages to talk to a consultant or watch an operation when one of his own cases is involved—very good for him and for the consultant and for the conduct of the case. These are all time-consuming activities and he is genuinely busy and useful. As the years go by his list grows, but the day remains the same length. He cannot afford to refuse that growing list.

Ten years later he will have become a second-class sorting machine, "passing the buck" whenever he can justify this to himself (and how easy it becomes), caring for his 4,000 to their satisfaction but to that of no one else, spending far too

¹ *A Surgeon's Journal 1915-1918*, by Harvey Cushing. London: Constable, 1936.

much of his time signing the certificates and prescriptions they demand, writing numerous inadequate little notes to the hospitals and clinics of the area, and, if he has much imagination, disliking his work and himself.

It may be, Sir, that a man who is a naturally rapid worker and good organizer really can care for 4,000—or 8,000—"properly." It is obvious that a muddler or leisurely worker cannot. The real point is that we want to encourage the average decent G.P. to look after a moderate-sized list well and comprehensively rather than have a huge list which he cannot possibly care for as he ought.

Some sort of balance between payment per caput and payment for work done must be our aim. The present maternity-case fees are a help. The payment of liberal fees for all the minor jobs, such as diphtheria immunization—done sometimes in clinics and sometimes by G.P.s—would do a little to further the same principle. Beyond that I see appalling administrative difficulties arising.

As regards the future of general practice I have given a very gloomy prognosis with profound conviction. I have indicated a hopeful line of treatment, with very great difficulties in the way. Have we collectively a sufficient realization of what is happening, and is going to happen, to make us do anything about it?—I am, etc.,

Woodford Green, Essex.

E. B. GROGONO.

Different Capitation Fees

SIR,—In the correspondence about sliding capitation fee I have seen no reference yet to what to me is a far greater injustice—namely, the difference in the capitation fee in different areas. In the Press to-day the capitation fee for the nine months is stated to be 13s. for Eastbourne and 11s. 5d. for Hastings. To have a difference of 1s. 7d. for two such similar places seems completely wrong. Cannot some scheme be devised to get rid of such discrepancies, as 1s. 7d. must mean a very marked difference in the incomes of two men who each have, say, 2,500 persons on their lists?—I am, etc.,

Farnham, Surrey.

G. H. WARD.

Early Bird

SIR,—I really thought that the limit had been reached as regards requests for certificates, but I was approached last week for what I consider is the star turn up to date. One of my male patients breezed into my consulting-room ("breezed in" is the right expression) and opened up the conversation by saying it was a long time since he had troubled me. I got his medical record-card out of the drawer and found that he last consulted me in July, 1947, on account of eczema, and that this disease was the only condition for which he had consulted me during the last six years. He is a fit-looking man aged 53.

He then stated that all he required was a note to say that he was not fit to run to catch a bus. Further inquiry elicited the fact that he is employed at one of those factories which are sufficiently large to have a private fleet of buses to transport the work-people to and from home, and anyone who has passed such a factory at closing time will have noticed the stamped certificate of employees to get to the buses. He then produced a certificate from the works doctor certifying that he could leave work five minutes early in order to catch the bus, and he informed me that the works doctor had told him to get a similar note "off his own doctor" to put things right. The man was quite indignant when I refused to issue the certificate, and he stated that "they were all getting them."

I expect the next certificate which the patient will demand from the doctor to whom he transfers will be one to enable him to leave work ten minutes early to avoid the rush of those leaving work five minutes early.—I am, etc.,

Manchester.

JAMES O'GRADY.

All-in Service

SIR,—It appears that the public are not fully aware of what was promised to them when the National Health Service came into operation. The four following points require consideration and should be pressed for:

(1) The insistence on the right of the community to avail themselves of benefits of the N.H.S. at any level—i.e., an individual cannot consult a doctor privately (as many thousands would) and be

entitled to have medicines (which are a much bigger imposition financially) supplied by the State.

Of course, such an individual would not be registered with a doctor, and therefore the capitation fee would be saved to the State.

(2) Patients who want to occupy private accommodation have to pay the full specialist and hospital charges. They cannot pay just the difference between private accommodation and State Service charges, to which they are entitled anyway. Here again a saving to the State would be effected.

(3) The problem of hostels for old people, particularly the financial side, has not been gone into nearly thoroughly enough. It is very costly for an elderly person or his relatives to pay £4 or £5 per week for maintenance in a hostel (although those I have heard about are fully worth this price). Thus a prospective inmate with accumulated capital of £600 would find it swallowed up in three years. The fear of this must prevent quite a number of would-be aspirants from applying to enter such hostels. Arrangements should be made for them to have this accommodation even though their capital has dwindled away.

(4) The plight of those in the middle classes who are semi-invalid or confined to bed is indeed pitiful. The drain on their accumulated resources is very serious. Of course they may be admitted to a Social Welfare Institution or chronic-sick ward of a hospital if such accommodation is available, and it certainly is not to-day, or they (this is what happens in the great majority of cases) remain domiciliary patients in their own homes or those of their relatives. This in most cases entails the employment of trained or partly trained nurses, and changes of bed linen and other invalid accessories, which are in these days unreasonably expensive. A system of nursing grants; say from £4 to £6 (which latter is the cost of maintenance in the State hospital) for those who are unfortunate enough not to be able to avail themselves of hospital treatment should be instituted. Among this category, which cannot be regarded as being within the higher-income group, may be included the general practitioners themselves.

Another point has occurred to me with regard to the economy of this "all-in" health service—that is, the reclamation of gold from dental plates on the demise of the wearer. In the same way glasses procured as National Health Service benefits should be returned.—I am, etc.,

Ruthin, Denbighshire.

TREVOR HUGHES.

Mileage Payments

SIR,—Surely it would take but little trouble for our executive to ascertain how much *per mile travelled* we are being paid. My own figure for the first nine months works out at nearly 6d. per mile now that a final payment has been made. Can anyone seriously suggest that this is reasonable? How can it happen that in a national service one executive council is able to pay 25% more than its immediate neighbour?—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

Abolish Assistantships

SIR,—While I have contributed to the correspondence on abolition of assistantships (*Supplement*, Feb. 26, p. 115) I can find little with which to disagree in the reply of the one protagonist of assistantships ("A.B.C.," *Supplement*, April 2, p. 216). The fact is that he has completely missed the point. We do not object to a period of assistantship preceding a partnership or as training in introduction to general practice, but we do most strenuously object to the exploitation of young doctors with a view to neither partnership nor training.

It may be outside the experience of "A.B.C.," but it is certainly within the bitter experience of many of us, that doctors are employed to do the donkey work of a large practice at a mere pittance, because the very structure of the N.H.S. makes it almost impossible for them to achieve the glory of becoming a principal.—I am, etc.,

ANOTHER ASSISTANT.

Assistantships

SIR,—The views of your correspondent "A.B.C." (*Supplement*, April 2, p. 216) are understandable, coming as they do from a practitioner nurtured in an age when industry, opportunity, and enterprise were the main ingredients of success. However, it should now be obvious to all that all such arrangements as partnerships and assistantships are redundant except in so far as they suit the personal conveniences of the parties concerned. The attitude of "I had to do it the hard way, why shouldn't you?" dies hard, but once it has died there is

no clear reason why any man who has put in many years of arduous and costly training should not go forth into the world and earn a four-figure income.

The idea that a period of assistantship extending over months or years is necessary in order that he may learn his job is rather amusing. The period of apprenticeship is served in hospital under the "all work and no pay" system, and any doctor who has completed one or two house appointments in general medicine and surgery is, in my view, more than competent to deal with general practice as it is understood to-day, and certainly far more abreast of recent developments in medicine than are the rank and file of his senior colleagues. The junior practitioner is more likely to err in the direction of over-caution as a result of his hospital training, so that, far from adding to his already stupendous mass of knowledge, a preliminary period of "unlearning" would appear to be indicated in order to enable him to arrive at a correct assessment of the clinical condition of his patients.—I am, etc.,

X. Y. Z.

Graduated Capitation Fee

SIR,—There have been a number of letters in the *Supplement* of late by doctors with large lists imputing to doctors with small lists laziness, inefficiency, and unpopularity; also suggestions that such doctors are being subsidized by colleagues with large lists. Counter-imputations of money-grubbing, popularity-seeking, and hurried work could likewise be made against large-list doctors by small-list doctors. It is not unlikely that such imputations and counter-imputations more or less cancel one another out from the point of view of justifiability. It remains indisputable, however, that the smaller one's list the greater one's expenses in relation to income. Rent, rates, food and fuel, attendance on door and telephoning, motor-car and telephone expenses—the main items of essential expenditure—are little affected by the size of one's list. The case, therefore, for a steeply graded capitation fee rests on a secure foundation on the grounds of expenses alone.

As to the charge of small-list doctors being subsidized: we are all paid from a common pool, and there is no need for any doctor to "subsidize" another by accepting on to his list more patients than the average number available to each doctor in the Service.—I am, etc.,

Wallacey, Cheshire.

LENNOX JOHNSTON.

Whither Medicine?

SIR,—May I express my modest appreciation of Lord Horder's address, "Whither Medicine?" (*Journal*, April 2, p. 557), which for me is a model of lucid exposition of our case, for a bigger voice in any scheme of National Health Service.

Ignoring recorded experience, the Health Minister has embarked on a policy of reckless beneficence which, as might have been foreseen, invites abuse.

That Lord Horder's historical survey will have any influence on our lawgivers is a hope too extravagant to entertain, but its careful study should convey the fact that omniscience is not the monopoly of the best-intentioned politicians of whatever shade. "Striving to better, off we mar what's well" is perhaps not inappropriate.—I am, etc.,

Southampton.

ARTHUR KING.

Exchange Control Medical Advisory Committee

SIR,—There is a medical dictum that "more mistakes are made by not looking than not knowing." This applies even to panels of "independent consultants," tuberculosis or otherwise.

It is one of the tragedies of present-day medicine that the opinion of the man on the job and seeing the case counts for so little with "officials" ranging from admission clerks doubting a diagnosis of, say, a fractured femur, to "leading specialists" doubting the suitability of treatment which has not the rubber stamp of being under their administration.

In tuberculosis there is another old saying, which even the Exchange Control Medical Advisory Committee will have heard, and that is that "each case is a law unto itself," which makes it rash for anyone to say that any case is too advanced to be permitted treatment.

Furthermore, when there is a long delay in waiting for sanatorium treatment (last week one of my patients with a T.B.-positive sputum was told he would have to wait four months for institutional treatment), are not the experts adopting a dog-in-the-manger attitude of "we cannot cure you and we are not going to let anyone else try"?

The case I have just quoted is all the more ironical comment on "expert panels" in that the man was invalidated out of the Royal Navy in 1946 (he enlisted in 1938) as a neurotic, although one of the x-ray reports taken in 1944 had queried Koch's disease, so even "expert committees" can be in error about tuberculosis. Lastly, is not control interfering with the fundamental human right to leave any country which was debated at UNO?

Manchester.

S. SHUBSACHS.

Tuberculosis Officers

SIR,—The announcement in the *Supplement* of March 26 (p. 160) concerning the status of tuberculosis officers will come as a shock to workers in this important branch of medicine. They are not to be called physicians and specialists but senior hospital officers. Consequently their salary range will be from £1,300 to £1,750. It is a pity that such a retrograde step has been taken at this time.

Up to July 5 the more enlightened public authorities were trying to increase the status of tuberculosis officers. During the past ten years their clinical responsibility has considerably increased. There are now large refill sessions and anything up to 200 refills a week. The tuberculosis officer has charge of in-patient beds. Owing to the bed shortage he has to do a vast amount of domiciliary visiting and frequently to initiate collapse therapy in the patient's home. The pre-war days when the patient could be got into a sanatorium within a fortnight of being notified are now gone, and he is under the care of the tuberculosis officer for many months before going to a sanatorium. In addition, the tuberculosis officer is now expected to have a good knowledge of all diseases of the chest and is asked to give specialist opinion when patients are sent to him whether they are suffering from tuberculosis or not.

Tuberculosis is an important disease and those afflicted by it are usually young people. Consequently it is well worth while to be able to treat them efficiently and to give them many years of useful life. Tuberculosis has always been looked down on, and its care has been an offshoot of the Public Health Department. This classification can only reduce the numbers of trained physicians who will wish to specialize in this branch of medicine, and the patient will suffer.—I am, etc.,

London, W.2.

P. F. KENNISR.

Cause of Hardship

SIR,—At a recent meeting of our B.M.A. Branch it was stated that 37% of doctors in the United Kingdom have less than 1,000 patients. This is a staggering figure and would be even if the number were less than 2,000, and makes the loading of the first 1,000 patients a duty. One reads many indignant letters from doctors with the maximum number of patients against this suggestion, many stating that they have worked so hard in the past under uncongenial surroundings that they should now be very liberally rewarded.

Personally, I work in an industrial town in Lancashire and I find neither the work nor the surroundings uncongenial. I work here because I like it. There are few, if any, industrial towns or cities without good country within a few miles. The doctors now hardest hit did not ask for the new Service nor did they complain before July, 1948. They did a job of work for which they must have been satisfactorily rewarded in spite of the small numbers of patients they cared for, and it is only the new imposed method of remuneration which has caused hardship. They are still doctors, still colleagues, still entitled to a decent living, and the sooner the idea is banished that only the efficient doctor has large numbers of patients the better. If this last were correct, then efficiency and all the other adjectives applied to the doctor with the large list could be freely bought before July 5, 1948.—I am, etc.,

St. Helens, Lancs.

Branch and Division Meetings to be Held

CARDIFF DIVISION.—At Lecture Theatre, The Engineer's Institute, Park Place, Cardiff, Wednesday, April 27, 8 p.m. Mr. Ralston Paterson: "The Application of Radiotherapy to the Treatment of Squamous Carcinoma."

GREENWICH AND DEPTFORD DIVISION.—At Brook Hospital, Shooters Hill, Woolwich, London, S.E., Thursday, April 28, 2.30 p.m. Dr. J. V. Armstrong: Clinical demonstration of fever cases. Members from neighbouring Divisions are specially invited.

MID-ESSEX DIVISION.—At Chelmsford and Essex Hospital, Sunday, May 1, 10 a.m. Mr. O. S. Tubbs: "The Modern Treatment of Congenital Heart Disease."

SCARBOROUGH DIVISION.—At Scarborough Hospital, Thursday, April 28, 8.30 p.m. Mr. D. W. Currie: "Carcinoma of the Cervix."

Meetings of Branches and Divisions**DUMFRIES AND GALLOWAY DIVISION**

At a meeting held on March 27 Mr. W. S. Mack, Glasgow, gave an interesting address on "Male, Female, and Inter-sex." The lecturer briefly discussed the historical aspect of hermaphroditism, and then reviewed some of the more recent work on the subject. The lecture was illustrated by lantern slides.

ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION

A meeting was held at Rochester on March 20, with Dr. H. J. Hoby in the chair. About 40 medical practitioners were present.

The meeting was addressed by Dr. J. A. Gorsky, on (a) Constitution of the B.M.A.—The Legal Situation as to the Formation of a Medical Trade Union, and (b) Remuneration of General Practitioners.

It was resolved (a) that a new body be established for the better protection of the interests of the medical profession in disputes with public authorities and other bodies, but that in view of the fundamental conflict of legal opinion on some of the most important points considered by the committee the matter should be referred back

for further consideration; (b) that the recommendation of the General Medical Services Committee as submitted to the B.M.A. Council with regard to remuneration be approved.

The resignation of Mr. Heath as Representative was accepted with much regret and a vote of thanks was extended. Dr. M. Landau was elected Representative.

H.M. Forces Appointments**TERRITORIAL ARMY****TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS**

Lieutenant-Colonel D. G. Rice-Oxley, M.C., T.D., having exceeded the age limit, has relinquished his commission, retaining the rank of Lieutenant-Colonel.

Major G. M. Frizell, T.D., from Active List, to be Major, and has been granted the honorary rank of Colonel.

Majors W. R. Sprout, T.D., and J. M. F. Whitby, T.D., from Active List, to be Majors, and have been granted the honorary rank of Lieutenant-Colonel.

Major J. A. Anderson, M.B.E., from Active List, to be Major. Captain (War Substantive Major) I. G. Hardinge, from Active List, to be Captain, and has been granted the honorary rank of Lieutenant-Colonel.

Captain (War Substantive Major) J. A. S. Brown, T.D., from Active List, to be Captain, and has been granted the honorary rank of Major.

Major B. F. Longbotham, from Active List, to be Major. (Substituted for the first notification in a *Supplement to the London Gazette* dated Dec 7, 1948.)

Captain J. Nicholson, from Active List, to be Captain, and has been granted the honorary rank of Major.

Captain J. S. Macgill has relinquished his commission on account of disability and has been granted the honorary rank of Major.

Captain (Acting Major) G. T. Ashley, from Active List, to be Captain, and has been granted the honorary rank of Lieutenant-Colonel. (Substituted for the notification in a *Supplement to the London Gazette* dated Oct. 12, 1948.)

Captain (War Substantive Major) D. H. Thomson, M.B.E., from Active List, to be Captain, and has been granted the honorary rank of Lieutenant-Colonel.

REGULAR ARMY: EMERGENCY COMMISSIONS**ROYAL ARMY MEDICAL CORPS**

War Substantive Majors A. W. S. Thompson, E. G. Holmes, J. Marshall, and E. E. Satchwell have relinquished their commission and have been granted the honorary rank of Lieutenant-Colonel.

War Substantive Major I. G. Cameron has relinquished his commission and has been granted the honorary rank of Major.

Captain G. R. Ellis has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

Captains H. N. Reed and J. Ryder have relinquished their commissions and have been granted the honorary rank of Major.

Captain J. White has relinquished his commission on account of disability and has been granted the honorary rank of Major.

War Substantive Captain R. J. Elsberg has relinquished his commission and has been granted the honorary rank of Major. (Substituted for the notification in a *Supplement to the London Gazette* dated March 23, 1948.)

ROYAL AIR FORCE

Group Captains E. C. K. H. Foreman, C.B.E., and J. MacC Kilpatrick, O.B.E., to be Air Commodores.

Wing Commanders H. C. S. Pimblett, C. Crowley, G. A. M. Knight, F. W. P. Dixon, M.B.E., C. A. Rumball, O.B.E., K.H.P., to be Group Captains.

Wing Commander G. S. Strachan has retired on account of medical unfitness for Air Force service, retaining the rank of Group Captain.

Wing Commander G. O. Williams has retired.

Squadron Leaders W. K. Stewart, A.F.C., J. L. Roche, H. L. Jenkins, R. C. Jackson, P. A. Wilkinson, J. I. M. Smith, C. G. Burgess to be Wing Commanders.

Flight Lieutenants W. B. Thorburn, A. J. Barwood, D. Crichton, M.B.E., and T. N. N. Brennan to be Squadron Leaders.

To be Squadron Leaders: J. W. Reade, G. R. Bedford, T. H. Redfern, and P. H. Blakiston.

Flying Officer R. I. Meanock to be Squadron Leader.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

LONDON SATURDAY APRIL 30 1949

BASAL-CELL CARCINOMA (RODENT ULCER), WITH SPECIAL REFERENCE TO LESIONS ON NECK, TRUNK, AND LIMBS

BY

Sir CECIL WAKELEY, K.B.E., C.B., D.Sc., F.R.C.S., F.R.S.E.D.

Senior Surgeon and Director of Surgical Studies, King's College Hospital; Surgeon, Royal Masonic Hospital and Belgrave Hospital for Children; Consulting Surgeon, Royal Navy

AND

PETER CHILDS, M.Ch., F.R.C.S.

Surgical First Assistant, King's College Hospital

[WITH PHOTOGRAVURE PLATE]

During the last thirty-five years 237 cases of rodent ulcer have come under the care of one of us (C.W.) and 210 of these occurred on the face or scalp, while 27 were found to arise outside those confines (Figs. A and B). Summaries of the case histories of these lesions found elsewhere than on the face or scalp are now given.

Umbilical Region (3 Cases)

Case 1.—A man aged 58 presented himself in 1930 with a large rodent ulcer to the left side of the umbilicus. He had first noticed a small pimple in this region some 12 years previously. The ulcer was irregular in outline with a heaped-up and rolled-over edge (Fig. C). The ulcer measured 1½ in. (3.75 cm.) at its greatest diameter, and its base was moist and some parts covered by small sloughs. There was no enlargement

of axillary or inguinal glands. Excision of the ulcer together with the umbilicus was undertaken through an elliptical incision. Recovery was uneventful. Microscopically the ulcer was a typical basal-cell carcinoma. This patient was last seen in 1939, when he was in good health and there was no sign of recurrence.

Case 2.—A man aged 60 was first seen in October, 1937, with a small rodent ulcer just below the umbilical margin. It had been present for two years and was gradually getting bigger. The ulcer had an

FIG. C.—*Case 1.* Rodent ulcer of the umbilical region. This lesion started as a pimple 12 years previously.

irregular edge and was ½ in. (1.25 cm.) across at its greatest diameter. Excision was undertaken through an elliptical incision. Recovery was rapid and the patient was discharged from the hospital on the fourth post-operative day. Microscopically the growth was a typical basal-cell carcinoma. The patient was well, with no sign of recurrence, two years later.

Case 3.—A seaman aged 47 with a small raised growth just above the umbilical margin. There was a small area in the centre of the tumour thought he had been stung by a bee at Alexandria some ten months previously. Growth was hard, with a raised, no palpable glands in the axillary region. Excision was undertaken through an elliptical incision. Recovery was uneventful. Histological report stated that it was a typical basal-cell carcinoma. He continued his war service and was quite free from any symptoms.

Chest Wall and Back (3

Case 4.—A man aged 59 was seen in 1942 with an irregular ulcer the size of a halfpenny in the middle of his back on a level with

FIGS. A AND B.—Diagrams illustrating distribution of rodent ulcers.

angles of the scapulae. The patient had been conscious of a lump on the back for some five years. Excision was undertaken through an elliptical incision. Recovery was uneventful. The histology was that of a typical rodent ulcer.

Case 5.—A man aged 64 was first seen in the out-patient department in November, 1945, complaining of an ulcer on the anterior chest wall about 1½ in. lateral to the right sternoclavicular joint. Some 19 years previously it had appeared as a spot the size of a pin-head. Gradually it became enlarged, and a crust formed on it. It was never raised above the adjacent skin surface. The ulcer was treated with x rays until March, 1947, at fortnightly intervals for courses lasting two to three months each. A total dosage of 4,100 units was given. Apparent cure was obtained twice but was followed by recurrence. On examination an irregular shallow depression was seen 1 in. (2.5 cm.) in diameter. It was almost entirely healed and epithelized, but part of the surface was covered by dry scabs. The surface was flat. The base was not depressed and the margin was not thickened or elevated, but there was an appreciable thickness and a certain stiffness as compared with normal skin. The ulcer was excised in June, 1947. The pathological report stated: "There is a central warty growth with several outlying nodules. It is not ulcerated. The cut surface shows no naked-eye evidence of infiltration of the subcutaneous tissue. Section shows the histological picture of a rodent ulcer. There is no deep infiltration of the underlying tissues" (Plate, Figs. 1 and 2).

Case 6.—A man aged 59 came under observation in December, 1948, with an ulcer on the left side of the chest wall. Thirty years earlier a small red nodule had appeared on the

FIG. D.—Case 6. Rodent ulcer of left chest wall. This lesion had appeared as a small pimple 30 years before. It had ulcerated only six years before. When seen in out-patient department the ulcer had become secondarily infected.

left chest wall level with the skin, and it had gradually enlarged. Ten years ago a scab formed over it, and six years ago it became ulcerated. On examination an ulcer was found on the left chest wall in the mid-axillary line (Fig. D). The size of the ulcer was ½ by 1 in. (1.9 by 2.5 cm.). The edge was irregular and

Anal Margin (4 Cases)

Case 7.—A man aged 62 was seen in February, 1915, with a small irregular ulcer to the left side of the anal margin. It was about ¼ in. (1.25 cm.) in diameter, and had been present for four years. The ulcer edge was hard and "rolled over" in places. There was no enlargement of the inguinal glands. Excision was performed under general anaesthesia, and a small part of the external sphincter and muscle was removed with the ulcer. Recovery was uneventful, with full sphincteric control. On histological examination the growth was found to be a typical rodent ulcer.

Case 8.—A man aged 64 was seen in December, 1920, with a small ulcer the size of a cherry stone to the right side of the anal margin. The patient had noticed a "pimple" for some years, but he could not be definite about its duration. Excision was performed under local analgesia and recovery was uninterrupted. The histology was that of a rodent ulcer.

Case 9.—A man aged 56 was seen in October, 1922, with a small irregular ulcer the size of a threepenny-piece situated at the posterior part of the anal margin. The patient had noticed the lump for five years. The growth was excised under

local analgesia, and recovery was rapid. The histology was that of a typical rodent ulcer.

Case 10.—A man aged 59 was seen in May, 1925, with a small irregular indurated ulcer to the left of the anal margin. It had been first noticed by the patient five years previously and was thought to have started in an external pile. On examination there was an ulcer with a raised edge. It was about 1 cm. in diameter, and in one area it involved the anal margin. Excision was performed under local analgesia, part of the external sphincter and being removed. Healing was rapid and there was no anal incontinence. Histology revealed a typical rodent ulcer.

Thigh (4 Cases)

Case 11.—A man aged 54 was seen in March, 1916, complaining of an irregular ulcer on the outer side of his right thigh. It was the size of a split pea, and had been first noticed as a pimple two years previously. The ulcer had hard "rolled over" edges and had been irritated by the uniform trousers which the patient wore. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 12.—A marine officer aged 49 was seen in February, 1918, with a small irregular ulcer measuring 1 cm. in diameter situated on the outer part of his right thigh. He thought he had knocked his thigh against a rail a year previously, but was not certain of this fact. The ulcer was excised under local analgesia. The histology was that of a typical rodent ulcer.

Case 13.—A man aged 58 was seen in 1926 with an irregular ulcer on the outer side of his right thigh just below the greater trochanter. It was about 1 in. in diameter and had grown from a small pimple to its present size in eight years. It was excised under general anaesthesia. Histology revealed a typical rodent ulcer.

Case 14.—A male clerk aged 49 was first seen in November, 1948, complaining of a growth on his left thigh. It had started eight years earlier as a small pimple and had increased slowly in size since then. It was not painful. There was a swelling the size of a halfpenny on the anterior surface of the left thigh 4 in. (10 cm.) vertically below the left anterior-superior iliac spine. Its outline was irregular, with raised edges and a slightly depressed centre. Consistency was firm and the edges were well defined. It was attached to skin, but not deeply. It was excised under general anaesthesia in November, 1948. Histological section revealed a typical rodent ulcer with some cystic degeneration (Plate, Figs. 5 and 6).

Legs and Feet (2 Cases)

Case 15.—A stoker aged 62 was seen in 1923 with a small ulcer the size of a split pea on the lower part of the anterior surface of his left leg. A "pimple" had been present for eight years, and he had worn a bandage over it while in the Navy during the 1914-18 war. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 16.—A carpenter aged 59 was seen in 1926 with a small ulcerated area on the dorsum of his left foot. It was the size of a cherry stone and had been present for five years. The edge of the ulcer was irregular and was "rolled over" in parts. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Neck (4 Cases)

Case 17.—A married woman aged 49 was seen in September, 1928, with a small ulcerated area the size of a split pea situated on the left side of the neck just lateral to the hyoid bone. It had started as a pimple eight years previously, when she was serving as a stewardess. The ulcer was irregular, with hard edges. Excision was performed under local analgesia. Histology proved the growth to be a rodent ulcer.

Case 18.—A man aged 59 was seen in December, 1931, with a small ulcer just above the suprasternal notch. It had been present for four years and had started as a pimple. It was about the size of a cherry stone, with irregular edges. The patient had not worn a collar for three years because of the ulcer. Excision was performed under general anaesthesia. Histology revealed a typical rodent ulcer.

Case 19.—A married man aged 62 was seen in May, 1933, with a small ulcer the size of a sixpence just to the right of the ala of the thyroid cartilage. It began as a pimple and had been present for three years. Excision was performed under local analgesia. The growth was a typical rodent ulcer.

Case 20.—A stoker aged 56 was first seen in July, 1936, with a ulcer the size of a large pea in the midline of the neck just above the suprasternal notch. The ulcer had hard raised edges and had been present for over a year. Excision was performed under local analgesia. Histology proved the growth to be a rodent ulcer.

Arms and Hands (7 Cases)

Case 21.—A stoker aged 52 was seen in March, 1919, complaining of an ulcer on the centre of his left forearm. This had first appeared seven years previously while he was working in a tanker. The ulcer almost healed at times, but always broke down again. When examined the ulcer was found to be the size of a threepenny-piece. Its edge was irregular and was firm in consistency. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 22.—An ex-miner aged 62 was seen in April, 1924, complaining of a small ulcer just above his left antecubital fossa. The ulcer had started as a pimple three years previously and had appeared to heal over at times. It was the size of a split pea and its edges were irregular and firm. Excision was performed under local analgesia. Histology proved the tissue to be a rodent ulcer.

Case 23.—A man aged 66 was seen in March, 1928, complaining of a small irregular ulcer on the upper anterior surface of his right upper arm. The ulcer had appeared as a very small lump three years previously. It was now an irregular raised growth $\frac{1}{4}$ -in. (0.6 cm.) in diameter. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 24.—A married woman aged 52 was seen in May, 1930, complaining of an ulcer on the outer side of her left upper arm. The ulcer had started six years previously as a pimple and had gradually increased in size. It appeared to heal on three separate occasions. The ulcer was shallow, with a raised "rolled over" edge, and was the size of a cherry stone. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 25.—A man aged 60 was seen in September, 1932, complaining of a small ulcer just below his right antecubital fossa. It had first appeared four years previously after a blow on the forearm by a hammer. It was irregular, with a hard edge, and was about $\frac{1}{4}$ -in. (0.6 cm.) in diameter. Excision was performed under local analgesia. Histology revealed a typical rodent ulcer.

Case 26.—An electrician aged 69 was seen in December, 1934, complaining of a small ulcer on the back of his left hand. It had started six years previously, after an electrical burn from a live wire. The ulcer was shallow, with an irregular hard outline, and was $\frac{1}{4}$ -in. (1.25 cm.) in diameter. Excision and repair of the defect by skin grafting was performed under general anaesthesia. Histology proved the growth to be a rodent ulcer.

Case 27.—A man aged 56 was seen in May, 1940, complaining of a small ulcer on the back of his left hand. The ulcer was the size of a split pea, and it had a hard irregular edge. Excision was performed under local analgesia. Histology showed the structure of a typical rodent ulcer.

Discussion

Basal-cell carcinoma, or rodent ulcer, is a tumour composed of ramifying, often pointed, processes which invade the dermis and subcutaneous tissues; or of lobules composed of cells which have the character either of the basal cells of the epidermis or of the cells lining the pilo-sebaceous ducts. Cells of true sebaceous type do not occur. Sometimes the connexion with the basal layer of the epidermis can be made out in sections; in other cases continuity with the pilo-sebaceous organs is demonstrable. The amount of stroma is variable, but is usually relatively

large. It may be fibrous in the chronic types and embryonic in the more malignant tumours (Sequeira *et al.*, 1947).

Epidermal skin carcinomata, whether of basal, squamous, or mixed type, arise intra-epidermally (Savataud, 1931). They are preceded by a hypertrophic change in the affected area of epithelium, which results in the formation of a pre-rodent keratosis, finer and flatter than that of a squamous epithelioma (Molesworth, 1927).

The natural history of rodent ulcers is well illustrated by the above case histories.

In 14 of the 25 cases the lesion first noticed was a "pimple" or small red nodule. Over a period of years, ranging most frequently from four to eight years, the lesion grows slowly; the shortest history in this series was of 10 months, the longest of 30 years. For some years there is no ulceration, but eventually the epithelium over the lesion breaks down. There may be abortive attempts at healing. This occurred in three cases of the series. Finally, however, the patient is seen complaining of a chronic ulcer varying in size from $\frac{1}{4}$ to $1\frac{1}{2}$ in. (0.6 to 3.75 cm.) in diameter.

The patient is in the sixth and seventh decade of life (the youngest in this series was 47, the oldest was 69). Only two of the 25 patients were female.

The ulcer is irregular in outline, with a heaped-up "rolled over" edge which is indurated and even hard to the touch. The floor may show clean granulations, or may bear sloughs, or may be scabbed over by crusts. There may be evidence of epithelization. There is little or no discharge. If the ulcer has become secondarily infected the base may be necrotic and the surrounding skin may show an inflammatory erythema and induration. Typically there is no fixation deeply. The regional lymph nodes are not enlarged.

Low- and high-power views of a typical rodent ulcer, and of a rodent ulcer showing cystic change, are presented in Figs. 3, 4, 5, and 6.

Clinical Varieties

The clinical appearance of basal-cell carcinoma is not uniform. The most satisfactory classification of the different types is that of Sequeira *et al.* (1947).

Superficial Cicatrizing Type.—(1) The lesion may present as an irregular sclerotic scar surrounded by a rim of small greyish elevations. The surface is smooth, but ulcerates when the lesion becomes more active. (2) A flat infiltration of the skin may be found, underlying an ivory or waxy surface. Ulceration occurs late.

Non-Cicatrizing Type.—This is the typical rodent ulcer. It presents as a chronic, indolent, slowly growing ulcer, which spreads superficially and deeply.

The Terebrant Type.—This lesion may be highly malignant from the start, or may succeed the preceding types. New growth and ulceration progress very rapidly, in depth rather than on the surface, and the tumour is of great local malignancy.

Multiplicity of Lesions

Molesworth (1927) said that multiplicity of lesions in cases of rodent disease was commonplace in Australia. In this country rodent ulcers are often single, though two or three lesions in the same patient are not uncommon.

There is, however, a group of cases in which multiple rodent ulcers are found as described by Sequeira *et al.* (1947) and Johnson (1945). The lesions appear to be identical with those described by Little (1923) under the name "erythematoid benign epitheliomata." These multiple lesions are basal-cell carcinomata of the superficial cicatrizing variety. They occur in the form of a red plaque, at the edge of which is seen a very faint, wax-like, shiny, sinuous margin, narrow and raised; much flatter than the rolled edge of a typical rodent ulcer but clearly of the same

nature (Little, 1923). Histologically a basal-cell carcinoma is seen with unusually shallow invasion of the corium by epithelial down-growths. These multiple superficial lesions are usually numerous, and are diffusely placed over the trunk and limbs. They may be associated with a more characteristic non-cicatrizing rodent ulcer somewhere on the body.

Site

Bland-Sutton wrote: "Although rodent ulcer arises mainly on the face . . . it may occur on the neck and pinna, but never, so far as I know, on the limbs." Molesworth (1927) had not seen rodent ulcer on the hands or forearms; epithelial tumours in these areas he found always to be squamous epitheliomata. Sutton and Sutton (1942) said that the nose, forehead, upper lip, and covered parts of the trunk and extremities were preferred. Sequeira *et al.* (1947) described the site of election as the face above a line drawn just below the lobule of the ears and crossing the face below the nose. The inner and outer canthi, the side of the nose, particularly the alae, and about the ears were the commonest sites; rarely the lips were affected. Basal-cell carcinoma of the trunk were rare.

We have pointed out earlier in this paper that differentiation should be made between the typical non-cicatrizing type of rodent ulcer and the multiple superficial type. The latter is found diffusely distributed over the trunk and limbs. It is much less common to find typical single rodent ulcers in these sites.

Savataud (1923) quotes a case reported by Trimble in which an ulcerated basal-cell carcinoma involved a large area of the anterior abdominal wall. Johnson (1945) appears to have reported especially cases of multiple superficial rodent ulcers; among these there appear to have been one deep ulcer of the chest wall and one of the back. Lawrence (1941) reported two personal cases of basal-cell carcinoma of the anus and four cases found in the literature. Wilson (1941) reported four cases of basal-cell carcinoma of the vulva, and collected 23 additional cases from the literature; he included transitional-cell carcinomata among his cases. Newland (1936), among 600 personal cases of rodent ulcer, found five on the upper extremity and one on the buttock. Little (1923) recorded two cases of single superficial rodent ulcer, one on the buttock, and one on the thigh. Piérard and Dupont (1948) described under the name "nodular epithelioma" what were apparently cystic rodent ulcers—in one case on a leg, in the other on the scrotum.

Treatment

The morphoea-like or "card-like" tumours may be treated satisfactorily with CO₂ snow. Sutton and Sutton (1942) advocate Sherwell's treatment for small lesions: the lesion is curetted, and acid nitrate of mercury is applied. For rodent ulcers in general, however, choice of therapy lies between excision and irradiation.

Factors Which Influence Choice of Therapy

The following points demand consideration.

Site.—Regard must be had to both the accessibility and the proximity of important structures. Almost all rodent ulcers can be excised. With the development of skin grafting and plastic repair of skin defects there is now no site in which a rodent ulcer may be found which is inaccessible to surgical excision. Plastic repair of eyelids or nose can be readily performed. When irradiating rodent ulcers in some areas care must be taken that vital structures are not irradiated at the same time.

Surface Area of Lesion.—All small lesions are naturally the more readily excised. These lesions are also the more suitable for irradiation. Skin defects left by surgical excision can be readily covered by grafts or plastic repair. On occasion

the cosmetic effect may be better from irradiation of large areas, but greater exposure to irradiation is necessary, with its attendant disadvantages.

Depth of Penetration of Lesion.—This is difficult always to determine accurately. The more superficial a lesion the more accessible it is to irradiation, either by radium or by x rays. But superficial lesions are also readily treated by surgery. Surgery is the treatment of preference where penetration is deep into bone or cartilage.

Multiplicity of Lesions.—In certain cases multiple superficial lesions may be adequately treated with CO₂ snow—namely, those of morphoea or "card-like" type. In some cases superficial irradiation may have practical advantages over multiple excisions. But in the cases with deeper multiple lesions (and there are not usually more than two or three deep rodent ulcers in the same patient) surgical excision is not only practicable but the method of choice.

Age and State of Health of Patient.—Advanced age is not a contraindication to surgery. If the state of health of the patient is poor, local analgesia can almost always be used. Only rarely need a patient be condemned to irradiation on account of poor health. In patients of younger age groups surgical excision finds favour because with their longer expectation of life there is greater likelihood of the development of late complications of irradiation of the skin.

Availability of Apparatus and Trained Staff.—The amenities of surgery and persons trained in their effective use are more generally available than adequate radiotherapeutic apparatus and trained radiotherapists.

Surgical Excision and Irradiation Compared and Contrasted

Surgical excision is applicable to any lesion, and is directed to the area involved and no more. Irradiation becomes technically more difficult the deeper a lesion penetrates and the closer it lies to vital structures. Whereas one operation is required when surgery is practised, and the extent of excision necessary is readily gauged, multiple attendances for irradiation are often necessary, and dosage of irradiation is not standardized. Owing to uncertainty of depth of involvement irradiation may fail to destroy the deeper layers of cells. Some cells of the tumour may be resistant to irradiation. The peripheral extent of the growth may not be appreciated without surgical excision, and an adequate area of tissue may not therefore be irradiated.

The complications of surgical excision of rodent ulcers are negligible. Irradiation produces radiodermatitis, which may be followed by telangiectasis and atrophy; damage to vital structures not involved by the growth may be caused by gamma or x rays.

By surgical excision confirmation of diagnosis is obtained. Montgomery (quoted by MacKee and Cipollaro, 1946) showed that 13% of skin carcinomata, diagnosed clinically, as basal-cell epitheliomata, contained prickle cells. These mixed or basal-squamous-cell epitheliomata are more radio-resistant than pure basal-cell tumours.

Recurrences occur consistently in 5% of cases treated by x rays. There should be no recurrence with adequate surgical excision.

With regard to time lost from work, admission to hospital, and mental trauma, the advantages are with surgery. In almost all cases rodent ulcers may be treated in the out-patient department under local analgesia. Arrangements can readily be made for premedication of the patients to diminish their worry. There is no danger of failure to complete the treatment with surgery as there is with the repeated visits so often necessary with radiotherapy.

Lastly, in the treatment of the recurrences after failure of irradiation, surgery is the only satisfactory choice. Recurrences tend to be more radio-resistant than the primary growth.

Summary

Twenty-seven cases of basal-cell carcinomata (rodent ulcers) are described occurring in sites other than the face and scalp. The clinical varieties of rodent ulcer, the multiplicity of lesions, and their site are discussed.

Treatment by surgical excision and that by irradiation are compared and contrasted.

Surgical excision of all rodent ulcers is recommended.

We wish to express our thanks to the late Dr. ff. Creed, lately Director of Pathology, King's College Hospital, to Dr. H. A. Lucas, and to Professor H. A. Magnus, Professor of Pathology in King's College Hospital, for their assistance with the histology of these tumours. We wish to acknowledge the assistance of Mr. W. Smith, of the department of photography, King's College Hospital, who prepared the photomicrographs.

STREPTOMYCIN TREATMENT OF TUBERCULOUS BRONCHOPNEUMONIA IN CHILDHOOD

BY

R. McLAREN TODD, M.D., M.R.C.P., D.C.H.

Senior Lecturer in Child Health, University of Liverpool

[WITH PHOTOGRAVURE PLATE]

This report is concerned with the use of streptomycin for tuberculous bronchopneumonia in childhood, and is based upon the treatment of eight patients admitted between January, 1947, and April, 1948, to the streptomycin centres under the auspices of the Medical Research Council at Alder Hey Children's Hospital, Liverpool (7 cases), and the Royal Hospital for Sick Children, Glasgow (1 case). Two of the patients died, and the six survivors have been followed up for periods of between 6 and 22 months subsequent to admission.

Diagnosis

Tuberculous bronchopneumonia simulates other types of bronchopneumonia closely, the main clinical differences being the insidious onset, steady progress of symptoms, increasing pallor, flabbiness, and weakness, and the progressive character of the abnormal pulmonary signs in tuberculous bronchopneumonia (Naish, 1933). The evidence

upon which the diagnosis was based in our cases was as follows.

History of Contact.—The tuberculosis officer of the local authority co-operated with us closely during this investigation, and in seven cases a history of contact with a proved case of pulmonary tuberculosis was obtained (Table I).

History of Illness.—A period of ill-health varying from 27 to 90 days before admission to hospital was a feature,

TABLE I.—Contact History

Case No.	Contact	Site	X-ray Film	Sputum	Details of Contact
1	Stepfather	Lungs	Active tuberculosis	Positive	Living in same house, has had sanatorium treatment
	Stepfather's sister	Lungs	—	—	Living in same house until death from pulmonary tuberculosis two years ago
2	Mother	Lungs	Quiescent	Negative	Living in same house
	Brother (18 years)	Lungs	Active	Positive	Living in same house and nursing the child for one month before entering sanatorium
3	Grand-mother	Lungs	Active	Positive	Living in same house for first 15 months of child's life
4	Father	Lungs	—	—	Living in same house. Died of pulmonary tuberculosis, July, 1945
5	Father	Lungs	—	Positive	Living in same house
6	No known contact				
7	Mother	Lungs	Quiescent	Negative	" "
	Brother (3 years)	Glands in neck	Active	Negative	" "
	Brother	Lungs	—	—	Lived in same house until death, at age of 15, from pulmonary tuberculosis, 1945
8	Brother (8 years)	Lungs	Active	Positive (Guinea-pig)	Lived in same house, but now in hospital with pulmonary tuberculosis
	Sister (7 years)	Cervical glands; dactylus	—	—	Living in same house
	Mother—refused examination	Lungs	Quiescent	—	" "

and in two cases the illness followed an attack of measles. All the patients had shortness of breath severe enough for the parents to remark upon it; cough of several weeks' duration was present in seven cases, sputum was noted in one case, and loss of weight had been observed in half the cases.

Clinical Signs.—The most striking signs were pallor (7 cases), variable degrees of dyspnoea (7 cases), cough (7 cases) accompanied by vomiting (2 cases), and poor nutritional state (3 cases). The pulmonary signs were those of bronchitis (4 cases), consolidation (3 cases), and collapse of the left lower lobe (1 case). (See Table II.)

Radiography.—Radiographs of the chest showed patchy shadowing of the lung fields in all patients: in Case 4 it was

TABLE II.—General Clinical Signs on Admission of Cases to Hospital

Case No.	Nutrition	Colour	Dyspnoea	Clubbing	Glands in Neck	Cough	Sputum	Chest Signs
1	Poor; very emaciated	Pale; no cyanosis	Slight	Fingers and toes	Small	Moderate	—	Consolidation both bases Cavitation right upper lobe anteriorly
2	Poor	Pale; slight cyanosis	"	Absent	"	Severe, with vomiting	Yellow	Consolidation left lung anteriorly; bronchitic signs right side
3	Fair	Pale; no cyanosis	Stridor	"	None	Absent	—	Bilateral bronchitic signs
4	Good	Very pale	Slight	"	"	Moderate	Swallowed	Consolidation upper two-thirds left lung
5	Poor	Pale	Marked	"	Enlarged and bilateral	Severe	—	Generalized bronchitic signs
6	Fair	No cyanosis	Slight	"	None	Moderate	—	Generalized bronchitic signs
7	"	Pale	"	"	Small	Severe, with vomiting	—	Bronchitic signs at both bases
8	"	"	Absent	"	Marked enlargement, with discharging sinuses	Slight	Swallowed	Clinical evidence of collapse of left lower lobe; bronchitic signs in other lung fields

associated with massive consolidation of the left lung, in Case 8 with collapse of the left lower lobe, and in Case 2 with partial collapse of the left lung and compensatory emphysema. In Cases 3, 7, and 8 enlarged hilar glands were visible. A fine miliary type of mottling in addition to the coarse patchy shadowing was present in Case 5. (See Table III.)

Isolation of Organism.—*Mycobacterium tuberculosis* was obtained from stomach washings or sputum in all cases, was seen on direct film examination (Cases 1, 2, 5, and 6), and was isolated by culture (Cases 3, 4, and 8) or by guinea-pig inoculation (Cases 4 and 7). The tubercle bacilli were of the human variety in seven cases and bovine in Case 3.

Tuberculin Reaction.—In five cases strong positive reactions to 1 in 10,000 old tuberculin were obtained; in two cases a dilution of 1 in 1,000 was positive; and in one case the test was negative at 1 in 10,000 but was not tested with higher concentrations.

Course of Illness After Admission to Hospital and Before Starting Streptomycin

Case 2 received streptomycin from the day of admission to hospital, but the remaining seven cases were observed for

periods varying from 17 to 102 days before streptomycin administration was started. An assessment of the clinical condition during this period before streptomycin treatment has been made in Table IV.

Case 3 was admitted for the treatment of suppurative otitis media, and initially no abnormal chest signs were noted. Bronchitis first developed on the 48th day of observation. Fever was minimal except on the 97th day, when a temperature of 104° F. (40° C.) was recorded. No obvious deterioration in general condition was observed. In contrast, the course in Case 1 was progressively downhill: this patient lost 1½ lb. (570 g.) in 17 days, his temperature reached 102° F. (38.9° C.) daily, and the respiratory signs increased in severity. Similar evidence of increasing consolidation was noted in Case 4 and the temperature was raised to 102° F. daily, but this patient's general condition was fairly satisfactory throughout. In the remaining four cases weight was stationary, appetite was fairly good, temperature was normal except for an occasional rise to 100° F. (37.8° C.), and no alteration in the chest signs was observed.

Streptomycin Administration

The streptomycin used was in the form of the hydrochloride, obtained from America (Merck), and the dosage

TABLE III—Details of X-ray Findings on Admission to Hospital (Radiologist's Report)

Case 1.—Gross changes in both lung fields typical of tuberculous bronchopneumonia, with cavitation on the left.

Case 5.—Diffuse bronchopneumonic tuberculous infiltration with finer miliary mottling.

Case 2.—Consolidation and partial collapse of left lung with compensatory emphysema. Bronchopneumonic changes in the right lung.

Case 6.—Bronchopneumonic changes in both lungs, but especially the left. Some de-aeration of left lower lobe. ? Tuberculous.

Case 3.—Opacity in left upper lobe and in right lower lobe due to consolidation of bronchopneumonic type; well-marked peripheral hyperaemia in all areas due to bronchopneumonic congestion. Both hilar shadows enlarged.

Case 7.—Bronchopneumonic consolidation of both lungs. Enlarged right mediastinal shadow.

Case 4.—Mediastinum enlarged to the left; areas of consolidation in right lung and massive consolidation of left lung.

Case 8.—Enlarged right hilar gland with infiltration at right base. Collapse of left lower lobe and bronchopneumonic shadowing in left upper lobe.

TABLE IV.—*Clinical Course of Patients from Day of Admission until Start of Streptomycin Therapy*

Case No.	Period of Observation	General Observations	Temperature	Weight	Appetite	Chest Signs
1	17 days	Lethargic and apathetic. Frequent bouts of coughing. Increasing pallor. Progressive loss of flesh.	Up to 102° F (38.9° C.) daily	Loss of 1 1/2 lb (570 g)	Good	Evidence of consolidation with cavitation?
2	Treatment started on day of admission					
3	102 days	Superficial skin sepsis. Right suppurative otitis media. Measles. Occasional bouts of sweating. Cough and dyspnoea from 48th day; later became cyanosed. Inspiratory stridor noted on 72nd day.	Up to 99° F (37.2° C) daily, 104° F (40° C) on 97th day	—	Poor	Developed bronchitic signs on 48th day
4	21 days	Fair general condition. Loose cough. Dyspnoea. No cyanosis.	Up to 102° F. (38.9° C) daily	—	Poor	Signs of increasing consolidation.
5	41 days	Admitted as whooping-cough (17/7/47) but not confirmed. On 1/8/47 developed marked cervical adenitis (No local cause in throat).	99–100° F (37.2–37.8° C)	Stationary	Poor	Bronchitic signs (Rad.ograph on 1/6/47 showed primary complex)
6	20 days	Quiet—resents examination. Occasional dyspnoea.	Normal	..	Good	Bronchitic signs
7	42 days	No dyspnoea.	99 to 100° F., with occasional spikes to 101° F (38.3° C)	..	Fairly good	..
8	48 days	Discharging sinuses in neck and axilla. Bouts of coughing. Dyspnoeic. No cyanosis.	Normal	Collapse of left lower lobe

adopted was 0.02 g. per lb. (454 g.) body weight every 24 hours, intramuscularly. The drug was dissolved in distilled water and was given in divided doses six-hourly. This regime was continued for a period ranging between 12 and 22 weeks, making a total dosage of 27 to 130 g. of streptomycin. Three patients showed evidence of mild sensitivity to streptomycin. In Cases 1 and 7 a maculo-papular rash was present on the limbs, face, and trunk. In Case 4 albumin, red cells, white cells, and hyaline casts were present in the urine, and in Case 1 albumin and pus cells were found; these reactions quickly disappeared when the drug was suspended temporarily. Eosinophilia was not a feature, and no effects on the vestibular apparatus were observed. Local soreness, erythema, and induration at the site of injection occurred in one case.

Sensitivity of *M. Tuberculosis* to Streptomycin

The method of testing was that used in two investigations undertaken by the Medical Research Council (1948) in which the sensitivity was compared with that of the standard culture H37Rv. In half the cases tubercle bacilli were not isolated after treatment with streptomycin had started. In three of the remainder (Cases 2, 4, and 8) the tubercle bacilli showed no increased resistance to the action of streptomycin, but in Case 1 increased resistance was observed. The details of the sensitivity tests are recorded in Table V.

Clinical Course

(a) Fatal Cases (2)

CASE 1

A boy aged 5 years 4 months had a history of measles 26 days before admission, followed by anorexia, loss of weight, apathy, and refusal to play. Unproductive cough continued from the time of the measles. The child's father, suffering from active pulmonary tuberculosis, was living in the same house. On clinical examination, nutrition was poor and loss of weight was obvious. The axillary and inguinal glands were enlarged and clubbing of fingers and toes was present. There was flattening and diminished movement of the right side of the chest, and dullness to percussion at both bases with rales. Cavernous breathing was noted at the right apex anteriorly.

Tubercle bacilli were seen in direct films (and later cultured) from stomach washings. Chest radiographs showed "gross changes in both lung fields typical of bronchopneumonia, with cavitation on the left side." The cerebrospinal fluid showed no abnormality (total protein 30 mg. per 100 ml., sugar normal, cells 2 per cmm.). Intramuscular streptomycin treatment in a dosage of 0.02 g. per lb. body weight per day (0.8 g.) was started. His condition deteriorated, and 23 days after the beginning of treatment a generalized erythematous rash was observed, albumin appeared in the urine, and treatment was temporarily suspended. One month later the left fifth metacarpal bone was noted condition had deteriorated. Two weeks' puncture revealed changes typical of, although there was no suspicion of abnormal neurological signs. The

and bronchopneumonic shadowing in the left upper lobe. The cerebrospinal fluid was normal. The Mantoux reaction (1 in 10,000) was positive (12 by 15 mm.).

Streptomycin treatment was started (1 g. daily in divided doses six-hourly), and after six weeks of treatment all the sinuses in neck and axilla had healed. There was a marked improvement in the general condition and appetite was good, but the chest signs were unchanged. After twelve weeks streptomycin was discontinued; the sputum still contained tubercle bacilli.

The patient was sent to a convalescent hospital. Her sputum has remained positive, and x-ray films of the chest show little change. Since streptomycin treatment has been discontinued there have been bouts of pyrexia up to 103° F. (39.4° C.) and her general condition has slightly deteriorated.

Discussion

1 The diagnosis of tuberculous bronchopneumonia presents difficulties because the clinical signs and radiological appearances may closely resemble those of non-tuberculous bronchopneumonia. In one of our cases, for instance, the radiographs were suggestive of staphylococcal pneumonia, and the correct diagnosis was reached by isolating tubercle bacilli from gastric washings after a prolonged course of sulphathiazole had produced no obvious radiological improvement. Patchy areas of atelectasis associated with bronchopneumonia or with allergic conditions may present similar radiological shadows.

In addition to areas of bronchopneumonia of varying size, the finely mottled appearance of miliary tuberculosis may also be apparent on the x-ray film, as in Case 5. The experience of Blacklock (1932) was similar. In his study of 148 tuberculous children who came to necropsy 58 showed mixed miliary and bronchopneumonic lesions. Macroscopically there was often much difficulty in distinguishing between an early bronchopneumonic lesion and a subacute miliary one, and histological examination was frequently essential for differentiation. This same difficulty was found in the radiological assessment and diagnosis of our cases.

Scattered bronchopneumonic areas with cavitation are occasionally observed radiologically in the shadowed area surrounding a primary focus. These areas may progress to extensive pulmonary destruction (Caffey, 1945), and thus may be confused with the cavitation of tuberculous bronchopneumonia—a condition in which dissemination of the infection has occurred to parts of the same lung or the opposite lung through rupture of a caseous lymph node into a bronchus.

2 As to prognosis it is generally considered that recovery is improbable, and the usual course is a progressive deterioration (Nelson, 1946). The seven cases studied at Alder Hey Hospital during these trials were the only examples of tuberculous bronchopneumonia admitted in this period, and they were all treated with streptomycin. The only controls that we can offer, therefore, were similar cases in the hospital during the two years preceding the trials.

(a) Duration of Survival and Mortality Rate.—During the two years (1945 and 1946) preceding this trial eight proved cases of tuberculous bronchopneumonia were admitted to Alder Hey Hospital. The length of stay in hospital and results of treatment were as follows:

	Sex	Age	Stay in Hospital	Result
T.D.	Male	8 months	4 weeks	Died
J.W.	"	11 months	9 days	"
J.N.	"	1 year 3 months	4 weeks	"
D.H.	"	2 year 8 months	7 days	"
M.M.	Female	1 year 9 months	8 weeks	Taken home against advice
F.R.	Male	1 year 10 months	4	Died
B.B.	Female	5 years 9 months	2	"
M.D.	"	6 years 5 months	4	"

Seven of these eight patients died in hospital after a stay of seven days to four weeks, and the remaining case was taken home in poor general condition after eight weeks.

The results of streptomycin treatment of our patients compare favourably with these figures, both in the duration of life and in the more favourable outcome. The two fatal cases survived for 12 weeks and 9 months respectively after the beginning of streptomycin therapy. The five cases making good progress have survived 16, 15, 10, 8, and 4 months after cessation of streptomycin therapy.

(b) Change in Weight.—Gain in weight is considered a reliable guide in assessing improvement in these cases. The details of increase in weight are recorded in Table VI.

(c) Isolation of Tubercle Bacilli.—Gastric lavage was performed at regular intervals both during and after streptomycin therapy. In the two fatal cases tubercle bacilli were isolated on every occasion. In Case 8, which showed temporary improvement, tubercle bacilli reappeared after two months of streptomycin therapy. In only one of the five cases showing marked clinical improvement were tubercle bacilli isolated from gastric washings after streptomycin therapy had begun; this was Case 4, in which tubercle bacilli were isolated 16 and 27 weeks after the starting of streptomycin therapy.

(d) Radiography.—Radiographs taken at regular intervals during the trials showed a gradual clearing of the bronchopneumonic areas over a period of months (see Plate). In Cases 3, 5, and 6 calcification appeared 14, 13½, and 12 months after treatment was begun.

(e) Pyrexia.—The temperature records were of little value in assessing progress of the cases. In Cases 5, 6, 7, and 8 temperature was normal during and after streptomycin administration. In Case 4 the temperature was normal during treatment except on five isolated occasions. In Case 3 temperature was normal during the first eight days of streptomycin therapy, and then figures of 101° F. (38.3° C.) were recorded daily. Clinically otitis media and tonsillitis had developed, and the temperature remained raised until these conditions had subsided. Three days later the temperature again rose to 101° F., and clinically the general condition of the patient had deteriorated and there was an increase in the chest signs. A transfusion of 300 ml. of fresh blood was given; thereafter the temperature remained normal. In Case 1 the temperature at 6 a.m. and 6 p.m. was above 100° F. (37.8° C.) for the first 25 days and often as high as 102° F. (38.9° C.). During the next 80 days it rose to 100° F. on three or four occasions each week; subsequently, normal temperatures were recorded. In Case 2 the temperature was normal except during the first three days of treatment and for the three days preceding death.

3 Tuberculous meningitis developed in one of our cases and was diagnosed by routine examination of cerebrospinal fluid before any abnormal neurological signs were present. It is suggested that the cerebrospinal fluid of all cases of tuberculous bronchopneumonia under treatment with streptomycin should be examined at two-weekly intervals during the first two months of treatment and at monthly intervals thereafter to detect early spread of disease to the meninges.

Summary

Streptomycin has been given to eight children suffering from tuberculous bronchopneumonia. Their ages at the beginning of treatment varied from 5 months to 12 years.

Two of these patients have died, and the six survivors have been under observation for periods of from 6 to 22 months.

The diagnosis of tuberculous bronchopneumonia presents difficulties because it closely simulates non-tuberculous bronchopneumonia, patchy collapse of the lung, and confluent miliary tuberculosis.

Gain in weight and radiological improvement in the lung fields are the two most valuable means of assessing progress.

In one child tuberculous meningitis developed during treatment and the organism became resistant to streptomycin.

This investigation was carried out under the auspices of the Medical Research Council Streptomycin in Tuberculosis Trials Committee (Chairman, Dr Geoffrey Marshall) at the centres at Alder Hey Children's Hospital, Liverpool, and the Royal Hospital for Sick Children, Glasgow. These two centres were under the charge of

R. McLAREN TODD : STREPTOMYCIN TREATMENT OF TUBERCULOUS BRONCHOPNEUMONIA IN CHILDHOOD

FIG. 1.—Case 3. Feb. 10, 1947. Bilateral hilar shadows: bronchopneumonic consolidation in left upper and right lower lobes

FIG. 2.—Case 3. Aug. 1, 1947. Marked improvement in right lower lobe.

FIG. 3.—Case 3. Oct. 15, 1948. Areas of calcification, especially at right apex, right midzone, and left apex: calcification at right base, probably site of primary focus.

FIG. 4.—Case 5. Aug. 27, 1947. Diffuse bronchopneumonic infiltration

FIG. 5.—Case 5. Jan. 1, 1948. Considerable improvement in periphery of lung fields

FIG. 6.—Case 5. Oct. 11, 1948. Calcification right base (probably site of primary focus) and right hilar glands

only one such case has been discovered." It appears that in this case vaccination has not given enough resistance because of deficient power of reaction. Frappier, of Montreal, hopes in the course of the next few years to have every child in the province of Quebec vaccinated with B.C.G. vaccine.

B.C.G. vaccination has been criticized and subjected to condemnation largely as a result of unfortunate experiences which can be eliminated by the observance of better technique in the preparation of the vaccine and its administration. Complications of the inoculation undoubtedly arise, but they can be avoided by proper precautions. Wilson (1947) has been critical of the suggestion that the practice should be adopted in this country, and has been replied to by Wallgren (1948). It would seem only fair that a scientific investigation of its efficiency in this country should be carried out with proper controls before embarking upon a national venture which by its biological nature will be damned outright by a section of the community.

Streptomycin

Streptomycin seems to have some control over the progress of tuberculosis in that the original experiments on guinea-pigs proved that the drug would arrest and even partially eradicate well-established tuberculosis in that animal. Hinshaw and Feldman (1945) recorded a favourable response in two-thirds of 75 cases, in some a clinical cure being recorded. Apart from a few unpleasant reactions depending upon dosage, impurities in the preparation, and idiosyncrasy, there is the disadvantage (and it is a disquieting one) that some types of tubercle bacilli are resistant to streptomycin. It would appear that these resistant strains, freed from the dominant restraint of the previously active ones, may infect other individuals and multiply in spite of streptomycin administration and account for much of the deterioration of cases under treatment after the initial improvement (M.R.C., 1948). There is the further consideration that a resistant strain can initiate the disease in other individuals and account for the widespread dissemination of the disease in a form for which streptomycin is innocuous.

In miliary tuberculosis a favourable response is obtained in a number of cases, but post-mortem examinations of fatal cases of tuberculous meningitis do not provide any histological evidence that the tuberculoma has been influenced by the drug; the associated meningeal exudate, however, may show considerable organization and thus account for the clinical improvement. There is a suggestion of a field of usefulness for streptomycin in primary infections, but it will be necessary to review the evidence when an extended trial has been made and a critical review is possible.

Conclusion

I have now completed my task within the limits of time and my competence. I shall not have failed, however, if I have focused attention upon some of the practical aspects of a common disease in infants and children, a disease which carries a heavy responsibility for death, sickness, and incapacity. If I began at the beginning it was because, as Aristotle said, "He who sees things from their beginning will have the finest view of them." If we study and understand tuberculosis in all its aspects in the young we will appreciate all the better the disease in the adult; so that nothing is lost, but perhaps much may be gained, by this approach. By concentrated effort in the preventive field and the use of all available facilities for diagnosis and treatment we can look forward with more hope for its eventual eradication.

THE EFFECT OF ENDOCRINES ON FIBRO-ADENOSIS

BY

H. J. B. ATKINS, D.M., M.Ch., F.R.C.S.

Director of the Department of Surgery, Guy's Hospital

A clinic for the investigation and treatment of the painful nodular breast was established at Guy's Hospital in 1937, and except during the years 1941–5 it has been functioning weekly since that date. At different times I have been assisted in the running of the clinic by various workers, but my thanks are due particularly to Dr. P. M. F. Bishop, endocrinologist to the hospital, who launched the project with me, and whose advice has always been available. All expenses incurred in the investigations have been defrayed by an annual grant from the British Empire Cancer Campaign.

I originally set out to investigate the effect of endocrine preparations on the disease which we now call fibro-adenosis, defined as "a painful or nodular condition of the breast not due to new growth, bacterial inflammation or fat necrosis" (Atkins, 1938). As this part of the investigation is complete I am submitting a report of the findings. The clinic is at present devoted to a clinico-pathological investigation into the effect of endocrines on established cancer of the breast and to following up the now considerable series of cases of fibro-adenosis.

A report has already been given of the early work in connexion with the administration of oestrogens, and androgens in the form of injections of testosterone propionate (Atkins, 1940), but a brief recapitulation of our findings may not be out of place.

Bearing in mind the importance of the psychological aspect of this condition and the subjective nature of many of the manifestations, together with the absence of any absolute standards of such objective phenomena as "nodularity," we were careful to control our results by submitting a parallel series of cases to a course of injections of sterile olive oil if the subsequent therapeutic agent to be investigated was to be injected, and to a course of chalk pills if the agent was to be taken by mouth.

In nearly every case a random sample of breast tissue was taken by biopsy from that part of the breast where the disease was judged to be most advanced, and submitted to histological examination. A second sample was taken at the conclusion of the treatment and at a corresponding

eriod in the menstrual cycle. In this way we were able to assess the clinical effect of the substance being investigated and, because the pieces of tissue removed for section were only random samples, to a limited extent the histological changes.

Oestrogens

Thirty-three patients were given oestrogen therapy. They received at least 80 mg. of oestradiol benzoate by injection in four weeks or 280 mg. of stilboestrol by mouth in eight weeks; 19 of these patients had much higher doses.

Our conclusions, based on a clinical follow-up of these 3 cases and set out in detail in the above paper (Atkins, 1940), were that oestrogens were harmful if given in doses large enough to be effective, and that the larger the dose the more harmful was the effect. We formed the impression that histologically the fibroblastic reaction, the epitheliosis, and the adenosis all tended to increase.

Androgens

Thirty-four patients received injections of testosterone propionate; 22 of them had at least 400 mg. in four weeks, and many received considerably higher doses.

It was found that the majority of the patients benefited temporarily by these injections but tended to relapse some weeks after the cessation of treatment. Further, eight of these patients suffered hirsuties, amenorrhoea, and deepening of the voice, and two of the eight had received only small doses of testosterone propionate.

One patient receiving large doses (1,200 mg. in six weeks) developed a carcinoma of the breast at the site of the original fibro-adenosis one year later, the only case at that time to develop carcinoma following fibro-adenosis.

Histologically some of the features of fibro-adenosis seemed less advanced after androgen therapy than before, but of this we were uncertain, and the acid test of sorting the pairs of slides with the labels obscured into "before androgen" specimens and "after androgen" specimens was equivocal. It was concluded, therefore, that the risks entailed in this form of therapy did not justify the temporary relief obtained.

It was at this stage that the war interrupted the investigations. They were resumed in 1946, when it was decided to investigate other methods of androgen administration, using the same techniques of clinical and histological control as those described above. The effects of administering androgens by mouth, by inunction, and by implantation were therefore explored, with the following results.

Twelve patients received 15 mg. of methyl testosterone by mouth daily for two months; seven were relieved of their symptoms for an average of seven months, the longest being eleven months; one was relieved of her symptoms only while her tablets were being taken, the symptoms returning immediately afterwards; three had no relief from their symptoms; and one did not attend the clinic again and cannot be traced.

Nineteen patients received 400 mg. of testosterone propionate in the form of "neo-hombreol" ointment applied to the breast in divided doses daily for a period of one month. Six of these were relieved for an average period of four and a half months after treatment stopped, the longest being nine months; even said that the pain was relieved while the ointment was being used, but recurred as soon as the treatment stopped; and six said that there was no relief of symptoms.

Eleven patients received 100 mg. of testosterone implanted deep into the breast tissue at the time that the first biopsy was performed. Of these, four were relieved of their symptoms for 1, 2, 3, and 6 months, followed by a relapse; two showed light improvement for the follow-up period (4 and 5 months); our were not relieved of their symptoms (one extruded the tablet after three months); and one complained that the symptoms were made worse.

The impression gained was that the patients receiving androgen therapy enjoyed a real though slight and only temporary improvement in their symptoms as a result of the androgen absorbed.

None of the cases receiving androgen in the above doses by mouth, by inunction, or by implantation developed symptoms or signs of masculinization, nor in this series was there any constant difference in the histological picture between the original biopsy specimen and the specimen taken after the administration of the androgen. It will be recalled that the histological changes effected by large doses of testosterone propionate by injection were not convincing, and this finding is directly at variance with that of Pricolo and Goisis (1946), who claimed substantial changes in the histological picture as the result of administering androgens in smaller doses than we had been using in our first series.

It must be emphasized that the only crucial test, where random samples of the breast are taken for biopsy, is for an independent histologist to examine the pairs of slides, each of which is given a code number, and to succeed in diagnosing these slides correctly as representing tissue before and after androgen therapy in a significant number of cases. The possibility that androgen therapy modifies the histological picture of the breast is not denied, but the extent to which it does so is far less than the paper cited above would lead one to expect.

Degrees of nodularity are not susceptible to exact measurement, but undoubtedly in a few cases the nodularity was less after androgen therapy. Before claiming these few findings as evidence of the effect of androgen therapy, however, it must be remembered that in a substantial proportion of cases of fibro-adenosis natural remissions occur. Furthermore, the feel of the breast in the majority of our cases receiving androgen therapy did not alter.

Discussion

In a high proportion of cases oestrogen therapy makes the symptoms and signs of fibro-adenosis worse and advances the histological changes characteristic of the disease.

In a substantial proportion of cases androgen therapy causes temporary improvement in the symptoms of fibro-adenosis. The safest, most effective, and most convenient way of administering androgens is in doses of 15 mg. of methyl testosterone by mouth daily for two months. Androgen therapy has less, if any, effect on the nodularity and no constant detectable effect on the histological picture.

My view is, nevertheless, that androgen therapy is not worth while in the disease fibro-adenosis. The pain, divorced from the apprehension, is rarely excessive, and the vast majority of patients, relieved justifiably of their apprehension, forget it. Where the pain is "intolerable" or "agonizing" it is not relieved even temporarily by androgens, and my experience during the early days of the clinic of removing in desperation both breasts in six cases so complaining, after everything else had been tried, has led me to believe that it is doubtful whether the pain is due to fibro-adenosis. Four of these patients still complain of "intolerable" or "agonizing" pain where the breasts were, and the remaining two have transferred their agony to other sites.

It is not justifiable to administer androgen therapy to these patients in the hope that this will prevent the onset of cancer (Loeser, 1938), as the case cited above exemplifies. It is not proposed here to enter into the question of the liability to malignant change in this disease, as this subject,

together with a full discussion of the pathology, significance, and natural history of fibro-adenosis, is to be made the subject of a further report elsewhere. Experience in the clinic has, however, led me to believe that, whatever views are taken about the possible precancerous nature of fibro-adenosis, these patients should be seen by their medical attendant at least every six months. I had thought originally that these continuous visits to the doctor might serve to emphasize and fix the fear of cancer in the patient's mind, but I find in practice that the effect is quite otherwise. Psychologically the patient is able to transfer the whole burden of responsibility to the shoulders of the medical attendant, where it should properly rest, and in the meantime cease worrying, in the knowledge that, in the remote chance of anything sinister developing, it will be dealt with without delay.

If the view is accepted that breast pain is due to the stimulation of nociceptive nerve endings by adjacent fibroblasts, and that these fibroblasts are elaborated in response to epithelial changes in the ducts, as many of the clinical features suggest (Atkins, 1939), then it is easy to see why androgens can have only a limited and temporary effect. Such effect as they do have is presumably the inhibition of oestrogenically stimulated epithelial growth, but without any modification of pre-existing epithelium, hence the absence of histological change. So long as the androgen is being administered inhibition will continue; but at a variable period after it is withheld the natural hormonal balance of the individual is resumed, and oestrogen-stimulated epithelium appears in the ducts with a consequent reactionary fibrosis and recurrence of symptoms.

There is really nothing that we know of at present which permanently modifies these processes apart from pregnancy and lactation, which revolutionize the physiological pattern, and the passage of time. Particularly about the menopause, fibroblasts disappear from the breast (there being no longer any considerable epithelial activity for them to restrain, if we care to think of it in that way) and they fulfil their natural function of being converted into inert collagen fibrils. When this happens the pain ceases. The administration of endocrines in an attempt to modify fibroblastic pain of this sort is not unlike the prescription of penicillin for an inflamed keloid scar—it may affect a little something, but does not get to the root of the trouble and is scarcely worth while.

Like fibroblastic pain in general, the pain of fibro-adenosis, which often varies with the weather, can frequently be relieved temporarily by radiant heat. X-ray treatment, on the other hand, is disappointing, and it cannot be denied that the most efficacious treatment is still that of Sir Astley Cooper (1829): a scrupulously careful examination, a confident diagnosis, a justifiable reassurance, and "the return of the patient with delighted affection to her family."

Conclusions

The effect of oestrogens on fibro-adenosis is harmful.

The effect of androgens may be temporarily beneficial, but it is not sufficiently so to encourage the use of these substances therapeutically in this disease.

The histological effect of androgens in therapeutic doses on breasts in cases of fibro-adenosis is inconstant.

CURARE-MODIFIED ELECTRIC CONVULSION THERAPY IN CASES WITH PHYSICAL DISEASE

BY

PETER D. W. SHEPHERD, M.B., B.S., M.R.C.S.

AND

DAVID C. WATT, M.B., Ch.B., B.Sc., D.P.M.

Assistant Physicians, Shenley Hospital

Many mental patients are denied the benefits of electric convulsion therapy (E.C.T.) because of physical contraindications. The purpose of this article is to show that, with few exceptions, even the most severe physical disability should not debar such patients from the use of this method. We here report the results obtained at Shenley Hospital in 50 cases in which the physical condition of the patients rendered them unsuitable for ordinary E.C.T., but in which, nevertheless, this treatment, modified by curare, was used.

Review of Literature

Textbooks contain few detailed instructions regarding contraindications to E.C.T., and wider literature shows a striking diversity of opinion. Thus Herskovitz (1943) is unwilling to treat with E.C.T. patients over 60 or those with any kind of heart disease (past or present) or tuberculosis. Cook (1944) considers tuberculosis an absolute contraindication. On the other hand, Feldman *et al.* (1946) have given E.C.T. to patients over 80, and Kalinowsky and Hoch (1946) do not think it contraindicated when the systolic blood pressure exceeds 200 mm. Hg or in the presence of active tuberculosis. In the main, however, its use in impaired cardiac function, chest disease, old age, and frailty is regarded as requiring careful consideration and as involving considerable risk (Sargent and Slater, 1944). Fractures, except slight vertebral crush fractures, are generally regarded as an absolute contraindication to E.C.T. A number of deaths have been reported where unmodified E.C.T. has been given to patients with heart disease (Jetter, 1944; Napier, 1944) and to elderly patients (Evans, 1943; Mayer-Gross, 1945), and sometimes treatment has had to be discontinued (Jones, 1943). Will and Duval (1947) report a death due to reactivation of old tuberculosis following E.C.T., and mention several other cases in which inactive tuberculosis became active and spread rapidly after treatment. Twenty-nine deaths due to unmodified E.C.T. have been collected by Will, Rehfeldt, and Neumann (1948). This bears out the general conclusion that in such patients unmodified E.C.T. is not without danger.

Respiratory paralysis, which accounts for most of the deaths so far resulting from curare-modified E.C.T., apparently presents no danger if the technique described by Hobson and Prescott (1947), and employed by us, is used. The electrocardiographic evidence that curare should not be used in cases of heart disease (Jones and Pleasants, 1943) is not borne out by clinical experience or by physiological experiment (McIntyre, 1947). Kalinowsky and Hoch (1946) state that patients dislike the sensation of curarization, but we have found that many patients prefer the modified treatment here described to ordinary E.C.T., as the anaesthetic eliminates the unpleasant feelings associated with E.C.T. as well as those associated with curare.

Technique

Our technique is the same as that employed by Hobson and Prescott (1947), except that a greater quantity of curare is used in order to modify the convulsion more effectively. In this way not only is the risk of fracture abolished but

the muscular effort is so slight that there is little or no rise in blood pressure. No cyanosis occurs throughout the treatment. *d*-Tubocurarine chloride is used to modify the convulsion. This is mixed with thiopentone and atropine, and the whole is given by rapid intravenous injection.

Routine investigations before starting treatment include x-ray examination of chest and spine, electrocardiograms, and of course physical examination. Treatment is carried out on an ordinary bed with one pillow under the head. Restraint is not necessary.

The initial dose of curare is based upon the body weight: .5 mg. per stone (6.35 kg.) for females, 3 mg. per stone or males. This is varied in subsequent treatments according to the effect on the individual case. We have not so far seen any case unduly sensitive to curare, but one patient (Case 43), weighing 7 st. 5 lb. (46.7 kg.), required 45 mg. of the drug. In the females of our series 0.25 g. of thiopentone and 1/100 gr. (0.65 mg.) of atropine was the standard dose, but in the males an initial dose of 0.15 g. of thiopentone was found to be satisfactory. The doses are altered in subsequent treatments if necessary.

Thiopentone is given to avoid apprehension and the very unpleasant sensation of curarization, also to facilitate artificial respiration. Atropine is employed to maintain a clear airway. Unconsciousness supervenes as curarization begins and is usually prolonged enough to allow full curarization to take place, while artificial respiration is carried out before the electric shock is given.

A Phillips airway is introduced as soon as breathing ceases, and oxygen is insufflated by means of the Lucas resuscitator. This allows a positive and a negative pressure to be given, while the bag automatically fills with oxygen when necessary. An ordinary 5- or 8-litre bag filled with oxygen, fitted to a three-way valve and face-piece and manipulated by the elbow—as in playing the bagpipes—is quite satisfactory, but the Lucas resuscitator is a distinct advantage.

Two to three minutes after the injection the electric stimulus is given and a major fit ensues. In a well-curarized patient there is no movement of the spine or ribs, but there are always some clonic movements of the face, enabling one to see whether or not a major fit is taking place.

Oxygen resuscitation is then continued until respiration starts spontaneously. The phase of apnoea lasts from 20 to 45 minutes. The majority of cases, however, are breathing again within 10 minutes. Movement begins first in the diaphragm, spasmodically and ineffectively, but rapidly becomes full and adequate. Prolonged apnoea gives rise to no real difficulty or anxiety, and unless a fall in blood pressure or other complication occurs there is no need for further intervention.

Nikethamide and neostigmine are kept at hand should they be needed, but we have had little use for them. In only two cases of our series—No. 5, in which there was progressive fall in blood pressure during a period of prolonged apnoea, when nikethamide was given intravenously to initiate spontaneous respiration, and No. 17—were further drugs found necessary.

Ten to 15 minutes after the recovery of respiration, during which time the airway has to be carefully watched and the jaw held, consciousness is regained. The patient then generally feels more comfortable sitting up.

Patients are able to get up and walk one to two hours after treatment. The frequency and number of treatments are the same as in unmodified E.C.T.—i.e., initially twice weekly. This is cut down to once a week after improvement has been secured.

With regard to the additional time taken for the method we have found that one doctor with an experienced nurse can treat six patients in two to two-and-a-half hours. We have not found the complication of laryngeal spasm, mentioned by Hobson, at all common. In fact, we have had only one such case, which was only partial and required no extra treatment.

The accompanying Table shows all the patients who received treatment here between July, 1947, when it was started, and August, 1948. They are arranged in the order in which they first received treatment. The Table gives an idea of the material selected and the results obtained. Physically the results are all favourable. There were no deaths or serious complications, and it will be noted that the number of mental recoveries is higher than is generally claimed for E.C.T. This is due, on the one hand, to the fact that no cases were treated unless the prognosis appeared favourable, and, on the other, to greater certainty of the diagnosis. Many of these patients had been here months or years and had been rejected for straightforward E.C.T. through physical disability. Thus the mental diagnosis had become established with the help of time.

Summary of Cases

1 Cases of Skeletal Disease.—Twenty such cases were treated. Ten of these had old fractures of the spine: in three the injury was known to have been due to previous E.C.T. Seven cases had other diseases of the spine—e.g., prolapsed disk, spondylitis ankylopoietica, tuberculosis, and Paget's disease of the spine. The remaining three had recent or malunited fractures of the pelvis or femur.

Sixteen of the twenty have been discharged recovered; three of the remaining four are recovered but have nowhere to go; the other discharged herself before treatment was finished. The average age of this group is 62 years, and their stay in hospital varied from a few weeks in some cases to many months in others. Case 26 had been continuously in hospital for 15 years and has now been discharged. All the cases were x-rayed before treatment and some afterwards, but as no movement of the spine took place further radiographs were not thought necessary. No case developed fresh symptoms or signs of the original bony lesion.

2 Cases of Hypertension and Cardiac Disease.—Seventeen cases with cardiovascular disease were treated. Twelve of these were hypertensives whose systolic pressure recorded at rest was over 200 mm. Hg; all had electrocardiograms which showed changes varying from uncomplicated left axis deviation to those of frank coronary and myocardial insufficiency. The E.C.G. of Case 45 showed a low voltage and inverted T waves in all leads without any severe left axis deviation, and suggested an old coronary thrombosis. Case 35 had well-marked bundle-branch block. These cases were given larger doses of curare, but the blood pressure did not as a rule rise more than 10 mm. even during the fit—when with full curarization it is possible to take an accurate reading of the blood pressure. In most cases the blood pressure and pulse rate remained unchanged.

Three cases of this group had auricular fibrillation—two secondary to hypertension, the other to a rheumatic heart. The pulse rate was controlled by digitalis, and although it was increased during treatment no case gave cause for anxiety.

The two remaining cases were of congestive failure: one (Case 17) is reported in full; the other (Case 29) was that of an old man of 77 who presumably had myocardial failure.

All patients in this group recovered mentally except two, who are only improved.

3. *Frailty and Senile Cases.*—Eight cases fall into this group. There were no fixed criteria, but five of these patients were under 5½ st. (34.9 kg.) at the start of treatment, and the others were more than 2 st. (12.7 kg.) below normal weight. In addition to this emaciation, half these patients were over 65 years, one was recovering from a gastro-enterostomy, and two had osteoporosis. All improved physically with treatment. Four recovered mentally; three of the others improved but have since relapsed; the remaining case was unchanged.

4. *Pulmonary Cases.*—Four cases of pulmonary tuberculosis were treated. Case 27 is reported in detail. Two were of quiescent pulmonary tuberculosis, both having symptomless fibrotic lesions; the other (Case 48) had chronic apical tuberculosis with cavitation. Case 14 had developed an empyema four months previously which was still present during treatment. No changes occurred clinically or radiologically with treatment. All five cases recovered mentally.

Complications.—Case 28 improved considerably, but treatment had to be stopped owing to repeated local thromboses at the site of injection. Congestive cardiac failure of mild degree occurred during treatment in four cases; but these were in patients with known cardiac disease, and no permanent disability ensued.

Four cases are reported in detail. These represent the four main types of case treated, and those that were most seriously ill are chosen.

Case 3. Depression and Hypertension

A business woman aged 54 became mentally ill in April, 1947, and was admitted as a voluntary patient in June, 1947, with a diagnosis of agitated depression. She was very restless and required much sedation. She had delusions of guilt and was mentally retarded. Her blood pressure on admission was 280/130, and an E.C.G. showed marked left axis deviation with inverted T1. An x-ray film of the chest revealed an enlarged heart. Her exercise tolerance was fair. Curare-modified E.C.T. was started on Aug. 8. She was given 23 mg. of curare on each of eleven occasions, and her blood pressure, which varied from 180/110 to 250/120 before the treatments, never rose more than 5 mm. during or after E.C.T. She recovered mentally and was discharged on Nov. 3. Eight months later, while still at home, she apparently relapsed and committed suicide by gassing herself.

Case 18. Depression and Fractured Spine plus Hypertension and Frailty

A housewife aged 64 first became mentally ill at Christmas, 1938, when she had insomnia and a tendency to worry unduly over trivial things. While in a general hospital having the B.M.R. taken she became suicidal and had to be admitted to

Case No.	Age	Sex	Indication	Mental Diagnosis	Result	No. of Treatments	Length of Stay Prior to Treatment	Remarks

a mental hospital. Since that time she has been continuously ill, having on three occasions been admitted to this hospital as a certified patient during her worst phases. On each admission her case was diagnosed as depression. She was apathetic, querulous, suspicious, and deluded. She expressed delusions that she was covered with lice and that her food was being doped by her husband.

Physically she was a poor specimen, weighing 6 st. 8 lb. (41.7 kg.). Her blood pressure was 170/95. An E.C.G. showed inverted T1, upright T2 and T3, marked left axis deviation, and multiple ventricular extrasystoles. A radiograph of the spine revealed an old wedge fracture of D7 with a synostosis of D3, 4, 5, and 6 and marked kyphoscoliosis of dorsal and lumbar regions.

In February, 1948, she had an attack of bronchitis, which brought about congestive cardiac failure with venous congestion in the neck and persistent mild cyanosis. On her recovery from this her mental condition remained the same. Treatment was started on March 16. She was given 20 mg. of curare with 0.25 g. of thiopentone and 1/100 gr. (0.65 mg.) of atropine followed by E.C.T. The convulsion was well modified, but after this her blood pressure rose to 220/130 and the pulse rate to 130 a minute. She developed severe engorgement of neck veins, which persisted for 20 minutes. With the administration of oxygen, however, these signs of cardiac embarrassment subsided.

At the second treatment, which was given three days later, 21 mg. of curare was given, as it was thought that the rise of blood pressure indicated an insufficient curarization. This time the onset of venous congestion was delayed five minutes after the E.C.T. It was then more severe than on the first occasion. The pulse rate became 150 a minute, blood pressure 180/100, and in addition she became very cyanosed in spite of adequate oxygenation of the lungs. Venesection was performed, 100 ml. of blood being removed. Her condition gradually improved, and 75 minutes after treatment she recovered completely. In view of her steady mental progress she was again treated four days later. On this occasion she was given 16 mg. of curare. She began to breathe spontaneously four minutes after treatment, but 10 minutes later her previous symptoms recurred. Venesection (200 ml.) was performed and she rapidly responded.

She recovered mentally, and it was decided not to treat her again unless she relapsed. In fact, in spite of getting a peripheral neuritis and, later, a cystitis, both of which cleared up, she has remained well and was discharged home two months later. A radiograph of the spine showed no change. It has been suggested that these attacks of congestive failure were initiated by attacks of paroxysmal ventricular tachycardia. Added to that, the fact that the heart failure was delayed up to 15 minutes after the injection makes it appear unlikely that the curare itself was responsible.

Case 27. Depression and Pulmonary Tuberculosis

A process engraver aged 57 developed malaise and fever in July, 1947. The fever settled and he went on holiday, where the symptoms recurred. He was admitted to hospital, pulmonary tuberculosis being diagnosed. The sputum contained tubercle bacilli. He was given a left phrenic crush and returned home after three months.

He was admitted to a sanatorium in March, 1948. Radiographs then showed slight apical mottling in the right lung, with extensive infiltration of the upper and middle zones of the left lung. He began to complain of "nerves," and that he was worried and could not sleep. Heavy sedation did not improve him, and as there was thyroid enlargement a therapeutic test of thiouracil was started on May 3. He became more depressed and agitated, and on May 8, after he had inflicted a wound on his left wrist with a razor, he was admitted to this hospital as a voluntary patient.

On admission he was depressed and sleepless, and would not eat his food. He continually worried over imaginary misdeeds and felt that the future was hopeless for him. His pulse remained over 100 and his B.S.R. was 30-65 (Westergren). His temperature remained normal except during an attack of erysipelas in the beginning of May.

Curare-modified E.C.T. was started on May 21. Before each shock he was given 20 mg. of curare, 0.15 g. of thiopentone, and 1/100 gr. of atropine intravenously. His pulse usually rose to 160, but his blood pressure rose no more than 20 mm. The convulsion was limited to clonic movements of the face and to arm rigidity. Oxygen was administered before and after the fit; his colour remained good throughout. He recovered within 30 minutes and gave no cause for anxiety.

He had nine treatments, and by June 21 he was cheerful and co-operative and ate well. He slept well, and showed no trace of his former delusions. He was able to be occupied in bed. His B.S.R. at the end of July was 13-26 (Westergren), his pulse remained between 80 and 100, and he had no pyrexia. He gained 3 lb. (1.36 kg.) in weight, and x-ray appearances showed no extension of the area of infiltration. He was discharged on July 21. One month later the x-ray appearances were unaltered.

Case 17. Depression and Heart Failure

A postman aged 60 was admitted to a general hospital on Dec. 14, 1947, suffering from heart failure. He had had bronchitis for 20 years. For three years before admission he complained of dyspnoea, and latterly he could not walk more than 100 yards (91.4 m.) without becoming breathless. On admission he was dyspnoeic, his neck veins were full, and rhonchi were heard throughout the chest, which was barrel-shaped and hyper-resonant. On Dec. 15 he got up in the evening and walked home in his dressing-gown and slippers because he "did not wish to wear hospital pyjamas without paying for them." He became suspicious and refused food. He declared that his case was hopeless and that he had caused all the deaths in the ward.

On Jan. 12, 1948, he was transferred to this hospital, under certificate, and was found to be in the state described above. On Feb. 24 modified E.C.T. was started, at which time he weighed 7 st. (44.45 kg.). Before each shock he was given 25 mg. of curare with 0.15 g. of thiopentone and 1/100 gr. of atropine intravenously. Artificial respiration with oxygen was carried out and the shock given three minutes after injection. The convulsion was limited to clonic movements of the facial muscles and slight arm rigidity. There was no cyanosis. Respiration had to be assisted for about 30 minutes after the convulsion. He was then propped up, and he usually recovered completely in one to two hours after the fit. On one occasion he was given 2 ml. of neostigmine and 2 ml. of nikethamide intravenously, as he had not recovered consciousness an hour after the fit. He had five treatments, by which time he became cheerful, was interested in his surroundings, and was eating and sleeping well. His physical condition had improved enough to allow moderate exercise, and he weighed 9 st. (57.15 kg.) when he was discharged on May 9.

Discussion

The cases of this series fall into two main groups: (1) those especially susceptible to bony injury, and (2) those in whom death is a possible outcome of E.C.T. In the former the advantages of diminishing the muscular contractions are obvious. Bennett (1940) and others first used curare in E.C.T. solely with this object. In the latter group the advantages are less obvious and are even open to question.

Hypertensive cases, which form a large part of this group, are given curare because, by diminishing the power of the muscular contractions, the blood pressure is less affected than during a fit unmodified by curare. It has also been shown by experiments on rabbits (Gross and Cullen, 1945) that curare has a direct effect on the smooth muscle of blood vessels and tends therefore to reduce the blood pressure.

In cases with established congestive heart failure the same argument applies—that the strain on the circulation, and particularly the heart, is lessened. Also, by abolishing cyanosis a theoretical advantage, at any rate, is gained.

Will and Duval (1947) have reported the treatment with unmodified E.C.T. of a patient with pulmonary tuberculosis in whom there was a rapid spread of disease. They quote experiments on rats and cattle which show that E.C.T. causes petechial haemorrhages in the lungs and they say these account for the activation of tuberculosis. They also suggest that curare might, by abolishing the violent movements and post-convulsive hyperventilation, provide a greater degree of safety in the shock treatment of the tuberculous patient. The avoidance of cyanosis with our technique is a further logical advantage.

We would like to stress the absolute importance of having available, and being familiar with, a suitable oxygen resuscitation apparatus before this treatment is undertaken.

Summary

The literature concerned with contraindications to E.C.T. and complications arising from it is discussed.

The technique of E.C.T., modified by *d*-tubocurarine chloride and thiopentone with assisted respiration, is described.

Fifty patients, untreatable by ordinary E.C.T., many of whom have been in a mental hospital for a considerable number of years, are reported as having been successfully treated by curare-modified E.C.T.

Four cases are reported in full.

The advantages of curare-modified E.C.T. in the various types of cases reported are discussed.

ACTING AS AN AID TO THERAPY IN A NEUROSIS CENTRE

BY

MAXWELL JONES, M.D., M.R.C.P.Ed., D.P.M.

Consultant Psychiatrist, British Postgraduate Medical School, Hammersmith; Senior Psychiatrist, Industrial Neurosis Unit, Belmont Hospital, Sutton

It has been known for many centuries that drama may effectively release emotional tensions in actors and audience or both. Since 1921 Moreno has been attempting to use drama for psychotherapeutic purposes, and in 1942 he founded his Theatre for Psychodrama in New York (Moreno, 1946).

We started to employ group methods in 1942 at Mill Hill Emergency Hospital, and began using plays for therapeutic purposes. At that time we had no knowledge of Moreno's work, but in recent years we have borrowed freely from him.

The Industrial Neurosis Unit at Belmont Hospital has 100 beds (two-thirds male and one-third female), and the patients stay in hospital for an average of two to three

months. The organization of the unit has been described elsewhere (Jones, 1947). The patients suffer from various neurotic complaints, mostly of a long-standing character, and the term "industrial" is used to indicate that the case represents a job-placement problem when the time comes to leave hospital. Patients of this type have usually a poor social adjustment, and may be actively antisocial. It has been found that group methods of treatment are particularly useful in treating this type of case. Only the use of drama will be considered here, although, of course, other types of individual and group treatment are used where indicated.

The Rehearsed Play

The plays are written and produced by the patients with the help of the nurses. About one week is spent in preparation and a play is presented weekly. The three wards on the unit take it in turn to produce one. A patient usually volunteers to present his own problem, but he may if he chooses, remain anonymous, or even write a play which presents some problem other than his own. The patient, having volunteered, is free to choose his own cast, producer, etc.; in other words, all the resources of the unit are put at his disposal so that he may be given every help to re-enact his problem as realistically as possible. No stage, curtains, or elaborate props are used, and the room is just large enough to hold the players and the audience. This is done to obtain an "intimate" atmosphere and avoid any suggestion of amateur theatricals; we want actors and audience to merge, and as many patients as possible to act or discuss or "act out" during the discussion. All the patients in my ward attend, and with the nurses and visitors about 100 people are usually present. Various production devices may be used—e.g., a whispered voice over the microphone to portray thoughts while the player mimes his anguish, etc., or a divided stage where two separate scenes are acted simultaneously, dialogue and mime being used alternately by each group of players.

Following the play, which represents a social or personal problem but never offers a solution, the group is asked by the psychiatrist to help the players to resolve the problem. The psychiatrist plays a largely passive part, content to allow the discussion to flow freely, intervening only if the discussion is becoming irrelevant or is being monopolized by one or two patients, etc. During the discussion it often helps to ask a contributor to demonstrate his point of view by working it out with the actual players. Thus a girl with a partial hemiplegia, the result of a birth injury wrote a play around her basic problem of social insecurity. She preferred not to act her own part, but during the discussion after the play found it impossible to remain anonymous. She was glad to re-enact several situations with the players, taking over her own role from the patient who had played it previously; such "acting out" allows the audience to "test out" a point of view much more realistically than by mere verbal discussion. At the end of the meeting, which lasts an hour, the psychiatrist tries to sum up and, if possible, to bring the various views expressed into something approaching a point of view acceptable to the group as a whole, or at least to the majority.

Reproduction of a Psychiatric Out-patient Interview

The psychiatrist simply reproduces an out-patient interview and a nurse usually plays the part of the patient. An old case record is used, preferably one where the psychiatrist has done a "follow-up" inquiry. The psychiatrist and nurse run through the interview beforehand. The psychiatrist knows the case well, and it is enough for the nurse to know the general trend of the interview, as she

gets her cues, from the doctor; she must try to act the part of the depressed patient or whatever is called for. If necessary, other psychiatric help can be invoked, and the psychiatric social worker, probation officer, disablement rehabilitation officer, etc., can appear in person.

Experience has shown that only simple situational problems should be raised, and there should be no attempt to develop any complicated treatment situation. At the end of the interview, lasting up to thirty minutes, the patients are asked what they would do if they were faced with this particular problem in the role of the psychiatrist. Again the discussion lasts until the end of the hour period, and the psychiatrist sums up, bringing the various points of view together, if possible, into an integrated whole. As before, there is opportunity for the patient taking part in the discussion actually to play the part of the doctor or patient and develop the interview along some particular line to demonstrate points more graphically than can be done by discussion alone.

Spontaneous Acting in a Small "Analytic" Group of about Eight Patients

Group treatment of an "analytic" type has been developed in recent years by many workers, including Schilder (1940), Wender (1940), and Slavson (1947) in the U.S.A., and Bion and Rickman (1943), Foulkes (1946), and Jones (1948) in Britain. Here a group of six to eight patients of both sexes meet for an hour a day for approximately two months. Patients are selected who have some form of social maladjustment, a good intelligence, and not a severe neurosis. The patients come to know something of each other's backgrounds and emotional difficulties. There is a common purposive goal—i.e., that the group should try to understand and help the individual. The atmosphere is essentially permissive, and the group stands for public opinion, which in time comes to be perceived as a much more friendly and understanding abstraction than when the group was first formed. Intimate confidences begin to be expressed and instinctual needs can be consciously formulated. Guilt is found to be much more universal than was at first realized, and is shared by all members of the group with obvious advantage—e.g., guilt over masturbation or hostility towards parents which previously may have been strongly suppressed. In this setting it is comparatively easy to get people to start "acting out" their problems. Thus a bus-driver who had a difficult domestic situation which he could not deal with satisfactorily was helped considerably by the group.

This man, aged 40, had been fairly happy in his home life before going overseas on active service. He was away from home for six years and returned to find the domestic situation completely altered. His wife had ceased to spend all her energies on her household duties: she now enjoyed the company of various women neighbours and was often away from home. Their son, now aged 17, went his own way, paying scant attention to his father or any other member of the family. Their little girl had been a baby when the father left home, and now regarded him as a stranger: the mother had done nothing to keep his memory alive. He returned to find he had no place in the family hierarchy. Added to this, conditions at work had changed; he now had a conductress in whom he had no confidence and who persistently gave the starting signal as some old lady was stepping off the bus, and so on. He felt tense and apprehensive all day when driving, and began to be quite obsessional about his time schedule. By the time he was off duty he felt exhausted and went home only to feel unwanted and frustrated. Finally he developed digestive symptoms suggestive of peptic ulcer, and was sent to hospital.

In the group this patient showed a good understanding of the other patients and a rare sense of humour. A scene was re-enacted when he returned home to his rather unfriendly wife and children and suggested that the whole family spent his day

off on Sunday at Kew Gardens. His son met the proposal with frank derision, and the little girl, taking her cue from the mother, showed a striking lack of enthusiasm. It was painful to witness the patient's suppressed anger, and one could almost visualize his red engorged stomach churning furiously. After this scene the group decided that somehow the patient would have to get to know his wife all over again. Various approaches were acted out, the patient often becoming completely inhibited as his hostility got the upper hand: it was much more difficult than just an intellectual understanding, and feelings seemed to crowd out his thoughts. But he made definite progress, which he began to apply when in the real setting of his home. At a follow-up six months after he left hospital he claimed proudly that he had "worked through" his domestic difficulties, and said that the family had had a most enjoyable outing at Kew Gardens.

Discussion

It is difficult to assess the value of any psychotherapeutic method, and in an in-patient unit such as the one at Belmont, where so many other factors—environmental, social, vocational, etc.—are at work, evaluation is particularly difficult. No critical assessment of our acting technique has as yet been attempted, but we are convinced that, taken in conjunction with other individual methods of psychotherapy, dramatic methods can aid treatment.

The rehearsed plays and the reproduction of a psychiatric out-patient interview are carried out in the presence of the entire personnel, patients and staff, of the unit. The patients are given a common social goal, and are asked to try to help with a real life problem concerning a fellow patient. It must be remembered that the industrial unit is largely composed of unemployed disheartened antisocial neurotic people, and one of our chief aims is to try to achieve some degree of resocialization: we believe that the plays bring the patients together and give them a social responsibility which, being shared, amounts to a group aim. The fact is that the patients are a remarkably good audience, and there is a large degree of participation in the discussion afterwards.

This group has definitely changed during the years we have been using a dramatic technique: the attitude now is one of much greater responsibility than formerly towards the person whose problem is being dramatized, and the group participation in the discussion afterwards is correspondingly greater. The other striking change is from anonymity to personal presentation, the latter now being the rule. This suggests the development of a group culture which is accepted by the group as a legitimate medium for the expression of personal problems. The plays usually raise very intimate problems and often invite censure; the fact that great tolerance and understanding are invariably shown must help to restore social confidence not only in the individual directly concerned but in all the patients who have identified themselves with their fellow patient.

The problems presented by the plays are of general interest, and it is easy for the individuals in the audience to project themselves into the situation enacted. In the discussion following the play various points of view are expressed, and the individual has an opportunity of gaining a more objective idea of the problem.

In the small analytic group of eight patients, meeting daily for up to two months, there is a much better opportunity for more specific therapy. We find it comparatively easy to pass from discussion to spontaneous re-enactment of some incident described by a member of the group. In this way it has been found possible to achieve mastery of a situation which in real life had overwhelmed the individual patient. By re-enactment in a friendly environment, in the presence of the psychiatrist, and with the knowledge that it is make-believe anyway, the individual may feel strong enough to cope with the problem enacted.

I doubt if an exact explanation can be given of the emotional relief felt subjectively on some occasions after "acting out," any more than the exact mechanism for the relief of anxiety following a painful abreaction during an analysis can be wholly explained—it is a fact, however, to which all those who have been analysed can testify. Where emotional "catharsis" actually occurs there is usually a sense of relief similar to the everyday experience of getting something off one's chest.

Conclusion

The various dramatic techniques described all aim at giving the individual an opportunity of expressing his thoughts and feelings in direct action or at least of projecting himself into a situation that is being enacted by others. Some of the advantages from these methods include the increase of group consciousness resulting from the patient's participation in a socially valuable group endeavour, an increased objectivity, the opportunity afforded for mastery of neurotic difficulties, and the liberation of pent-up emotions.

Many other techniques involving the same principles could be evolved, and Moreno has shown how valuable the psychodramatic method can be in many social spheres besides that of treating the neurotic—e.g., in the training of social workers by rehearsing home visits, etc. I have simply attempted to describe our use of psychodramatic methods to date, designed to meet our own particular needs in treating an in-patient neurotic population. No attempt is made to claim any specific therapeutic results by these methods. I do feel, however, that they have real value in supplementing short-term individual methods of treatment, and as the experience grows they may make a serious contribution to that most desirable goal—successful treatment of the neurotic in a reasonably short time.

I would like to thank Dr. Louis Minski, physician superintendent at Belmont Hospital, for his friendly co-operation in this work.

Medical Memoranda

Perforation as the First Manifestation of a Gastric Carcinoma

Perforation of a carcinoma of the stomach is an unusual event. We owe a classical description of the subject to Aird (1934), who collected details of 71 cases and described eight others treated at Edinburgh Royal Infirmary during the preceding ten years. It is significant that of the 71 references listed by Aird only five are from the British literature, and the most recent of these was published in 1904. The series of 506 cases of gastric cancer collected by Payne (1939) from the records of St. Bartholomew's Hospital includes six cases in which suture of a perforated carcinoma was performed, but no clinical details are given.

The diagnosis of the lesion may be considered in two parts: (a) diagnosis of the perforation, and (b) recognition of the presence of a carcinoma.

Symptoms consequent on the perforation generally follow on classical lines, but some cases pursue a more or less silent course, resembling in this respect perforations of the small bowel occurring in typhoid fever. However, in this event the primary growth or its metastases will already have undermined

the patient's health, and it is hardly likely that perforation of an early carcinoma will pass unnoticed. As regards recognition of the carcinoma, in a considerable percentage of cases its presence is already known and the perforation is but an incidental and terminal result of its extension. If the pre-operative findings have not already made the diagnosis certain, a laparotomy is nearly always bound to do so, either by inspection of the lesion or by the observation of metastases, which have been present in approximately half the recorded cases. A small residuum remain in which the history is inconclusive, metastases are not seen, and the perforated ulcer itself lacks the stigma of malignancy. It is the latter group which the following case is designed to illustrate. The case is unusual because the first evidence of gastric disease was provided by the perforation, the carcinoma was not recognized at the operation for its closure, and the patient made for a short time a complete recovery to normal health.

CASE REPORT

A man aged 60 was admitted to the Sheffield Royal Hospital on Nov. 26, 1946. He had been in his usual state of health until the day of admission, and although he had suffered from a mild degree of silicosis, due no doubt to his occupation as a grinder in a Sheffield cutlery works, he denied any past history of indigestion or of other symptoms immediately or remotely connected with his stomach. Ten hours before admission he was prostrated by sudden severe generalized abdominal pain which made him fall to the ground. It doubled him up and made him sweat, and during the course of the day pain was also felt at the tip of the left shoulder. After a few hours it decreased in intensity and he ate a little food, which caused him to vomit.

Examination showed an elderly-looking man lying quietly in bed. He had a good colour and was not sweating. The pulse was 100, regular, and of good volume; respirations 20. Generalized abdominal tenderness and board-like rigidity were present. Peristaltic sounds were heard, but the area of liver dullness was diminished. The clinical history therefore made it evident that a hollow viscus had perforated.

The abdomen was opened two hours after admission—12 hours after the attack began. Dirty free fluid containing fragments of undigested food welled up from the peritoneal cavity. Astride the lesser curve of the stomach, near the pylorus, was an ulcer which had perforated in its centre, the perforation admitting the tip of the little finger. An area of induration about 1 in. (2.5 cm.) in diameter circumscribed the central perforation. The stomach was mobile, with no suggestion of fixity, and the visible extent of the stomach wall at a distance from the lesion had a normal appearance. The liver adjacent to the stomach looked healthy, and in view of the apparently simple nature of the lesion the abdominal cavity was not explored. The perforation was oversewn with three catgut mattress sutures and the abdomen closed.

The post-operative course was uneventful. Gastric suction and intravenous infusion were maintained for 48 hours, and penicillin and sulphadimidine were given until the eighth post-operative day. The patient was discharged on Dec. 10, 14 days after admission.

On Jan. 6, 1947, he was examined in the out-patient department and appeared to be in good health. He complained of occasional epigastric pain after meals, and while it was considered that he might eventually be a candidate for partial gastrectomy the possibility of malignancy had not yet been entertained. A further examination on Feb. 17, however, showed a change for the worse. The pain, though still occurring only after meals, had become severe, vomiting had supervened, and he had evidently lost weight. A barium meal showed "chronic pyloric stenosis associated with a large gastric ulcer. The condition is probably due to adhesions arising from the previous perforation of the gastric ulcer, but the possibility of malignancy cannot be ruled out."

In view of the deterioration in his health, the patient was readmitted to hospital. A laparotomy on March 6, 14 weeks after the first operation, showed a carcinoma of the lesser curve of the stomach, fixed to and infiltrating the liver, and numerous tiny seedling deposits of growth scattered over the anterior wall of the stomach and throughout the peritoneum, omentum, and mesentery. The abdomen was closed and he was discharged to his home two weeks later, where he died on April 10, 1947.

COMMENT

Whatever one's views may be on the frequency of malignant change occurring in a simple gastric ulcer, there is no doubt in my mind that in this case the ulcer was malignant from the beginning. Considering that the primary lesion was so small when first observed, the rapid course of events after the perforation is remarkable. It is tempting to think that flooding of

the peritoneal cavity consequent on the perforation accounted for the diffuse seedling deposits scattered throughout the cavity. It is more likely that the rapid and silent penetration of the stomach wall, the early onset of fixity, and the widespread appearance of metastases were alike due to a rapidly developing anaplastic growth.

Cases occur from time to time in which the differentiation between an indurated simple ulcer and an ulcerating carcinoma cannot be made with certainty, and in such circumstances Bockus (1943) advises that a small section of tissue should be removed for biopsy. But it is in the very case in which carcinoma is unsuspected that one may be let down, and it would seem more prudent to make biopsy a routine in all gastric perforations treated by operation. Certainly, histological examination may yield equivocal results, but its employment in the case now described might have led to a more fortunate conclusion.

I thank Mr. J. C. Anderson for permission to publish the case treated in his wards, and Dr. J. L. A. Grout for the x-ray findings. Dr. Hart, of Sheffield, kindly informed me of the patient's progress at home.

Oesophageal Foreign Body in a Baby

The following case illustrates the importance of careful examination in cases of laryngeal obstruction in babies. The only satisfactory method of examining the larynx of a baby is that of direct laryngoscopy.

CASE HISTORY

The patient, a baby aged 1 year, was admitted to hospital on Dec. 9, 1947, with a history of stridor which had been present since Dec. 6, after he had been spoon-fed with hot soup. Soon after admission the baby was seen by Dr. Robert Hughes. His temperature was 102° F. (38.9° C.), pulse 140, respirations 40. The breathing was noisy and stertorous, laryngeal obstruction being obviously present; wet sounds were heard all over the chest.

I examined the baby later on the same evening in the operating theatre. The pharynx was seen to contain a lot of pus and debris when the direct laryngoscope was introduced; the suction tube connected to the steam vacuum apparatus was used to clear the field. There appeared to be no membrane or gross laryngeal oedema, the obstruction being caused by the presence of pus and debris. Suction was employed continually to clear the field, which was being repeatedly obscured by pus welling up from behind the larynx. Eventually the field was cleared, and a foreign body was seen wedged behind the cricoid. After disimpaction this was removed, and an acute erosion of the posterior wall of the oesophagus was observed from which pus was exuding.

The foreign body was a piece of bone, part of the lamina of the tail vertebra of a sheep. The small dorsal process had been responsible for causing the pressure ulceration of the posterior wall of the oesophagus. The piece of bone measured $\frac{1}{2}$ in. (1.6 cm.) in length, and its greatest diameter was $\frac{1}{4}$ in. (1.25 cm.). The baby was returned to the ward, and the administration of penicillin, 50,000 units four-hourly, was begun. The temperature fell to 98° F. (36.9° C.) by noon on the following day, and remained normal after this.

On the day after operation it was found impossible to spoon-feed the baby, but he could gulp fluids down from a cup. Debris from the pharynx had to be swabbed away continually. On Dec. 11, two days after the operation, spoon-feeding was attempted, but coughing was again caused, and it was found that drinking from a cup was preferable, as the coughing was not initiated. By Dec. 15 the baby looked perfectly well and took food easily, and thereafter made an uninterrupted recovery.

The history was completely elicited from the mother after the event. On Dec. 6 the child was given a plate of soup in a café, and the bones in the soup were allowed to remain on the spoon while feeding, as the mother was convinced that he would reject any; but the child choked after one spoonful, and was immediately taken to the casualty department of a hospital, where it was stated that there was no bone in the throat. She called her own doctor in to see the child two days later, and, being afraid of further ridicule if she mentioned

the bone again, suggested to him that the baby had been scalded by the hot soup.

COMMENT

The interest of this case lies in the diagnosis of the cause of the laryngeal obstruction present. The suggested causes were laryngeal diphtheria, retropharyngeal abscess, and exudative bronchitis. The diagnosis of retropharyngeal abscess was correct, abscess formation having followed the ulceration caused by pressure of the foreign body.

The presence of a foreign body in the oesophagus of the baby of 1 year in the absence of a history was a surprise. From the technical point of view the use of efficient suction enabled the field to be properly cleared, a correct diagnosis to be made, and the efficient removal of the foreign body to be effected.

Assistant Laryngologist,
Victoria Central Hospital, Wallasey

Thymoma Simulating Laryngeal Diphtheria

While there are many conditions which by pressure on the trachea or otherwise may simulate laryngeal diphtheria, thymoma is a very rare cause.

CASE REPORT

The patient, a boy aged 4 $\frac{1}{2}$, was admitted to this hospital on Jan. 8, 1947, with the history of sore throat off and on for nine days, occasional vomiting, and troublesome irritating cough. His mother had noticed a faint pink rash on the trunk, which disappeared in twenty-four hours. On the night of Jan. 7 he developed dyspnoea and was admitted to a general hospital in a state of extreme cyanosis. Tracheotomy was performed, and 40,000 units of antidiphtheria serum were given intramuscularly. His condition improved, and on arrival at this hospital his colour was good, pulse of good volume but rapid, and he was breathing normally through the tube. He was a very well nourished child; physical examination revealed nothing abnormal except a few scattered rales in the chest. A few hours later he developed another attack of dyspnoea and became extremely cyanosed. He was nursed in an oxygen tent, but his condition became steadily worse and he died soon after. Swabs from the nose, throat, and larynx were all negative for Klebs-Loeffler bacilli.

At necropsy a large capsulated pear-shaped tumour of the thymus was found. It extended from the lower poles of the thyroid (not structurally continuous with it) in front of the trachea to the anterior mediastinum. Adjacent structures were not invaded. There were prominent Malpighian corpuscles in the spleen but no general lymphadenopathy. Microscopically the tumour showed the general structure of a lymphosarcoma.

COMMENT

Tumours of the thymus are rare: in 17,000 necropsies Symmers (1911) found 25 thymic tumours—i.e., 0.14%. Diagnosis during life is difficult, as symptoms are few and not pathognomonic. Cyanosis, paroxysmal dyspnoea, and cough are the commonest; there may be pain, dysphagia, or hoarseness due to mediastinal pressure, and sometimes a swelling in the neck is found. Ewing (1928) reports a case with a history of repeated attacks of tonsillitis (cf. histology of tonsils and thymus). In myasthenia gravis, abnormalities of the thymus are found in about 30% of cases, and thymectomy has produced good results. I have not found any reports of cases in which laryngeal diphtheria was simulated.

Treatment is difficult; the scope of surgery is limited, but the sarcomata are radiosensitive and the prognosis is much more favourable than in the case of carcinoma or endothelioma.

I am indebted to Dr. Dawbarn, Walton Hospital, Liverpool, for the report of the post-mortem findings, and to the medical superintendent, City Hospital, Fazakerley, Liverpool, for permission to publish.

Reviews

PREGNANCY TESTS

Pregnancy Diagnosis Tests: A Review. By Alfred T. Cowie, B.Sc., M.R.C.V.S., Ph.D. Commonwealth Agricultural Bureaux Joint Publication No. 13. (Pp. 283. 15s.)

By the publication of this book the Commonwealth Agricultural Bureaux once more justify the claim of their organization to provide a service of great value to those for whose assistance it was designed. But many more than these will be grateful. The review is well done and well arranged. The author describes every kind of test and considers every kind of animal involved in the test. The magnitude of his task is indicated by the fact that one-third of this book (100 pages) is occupied by a list of the books and scientific papers that he has had to read and critically assess. It is of interest to note in passing that included in this list are two references to "unpublished observations" by the author himself.

Towards the end of the book he presents a summary and conclusions. These are somewhat disappointing, for they would seem to suggest that out of the enormous literature on this subject there is but little firmly proved that is sufficiently trustworthy and immediately applicable in the routine of pregnancy diagnosis. In the main this is due to the fact that in this summary the author omits all reference to pregnancy diagnosis in human medicine. In the veterinary field it seems that only in the case of the mare have these early laboratory diagnostic tests been shown to be of any considerable value.

This is indeed a book that was needed. Since anxiety can be stilled and hope sustained in the human subject, and since the management of his stock by the livestock breeder could be simplified and made more economical, by a confirmation of the existence of pregnancy at the earliest possible moment after conception, it is not surprising that there is a great and ardent demand for these tests. Since the demand for them is so great it is not surprising that biological scientists have everywhere been so busily engaged in refining the older tests and devising new ones. So much work of this kind has been proceeding during the last 25 years that it was high time that someone made a review of this kind and wrote a book like this one. It is the sort of book that everyone hopes that someone else will write, and therefore there will be very many who will be most grateful to the author.

F. A. E. CREW.

PHYSIOTHERAPISTS

The Growth of a Profession. Being the History of the Chartered Society of Physiotherapy, 1894-1945. By Jane H. Wicksteed, OBE, F.C.S.P. (Pp. 212. 6s.) London: Edward Arnold and Company, 1948.

In this little book Miss Wicksteed traces the history of the Chartered Society of Physiotherapy from 1894 to 1945. A good deal of the book is taken up by character sketches of the leading personalities, which will interest a limited circle of readers but which will be of great value to future historians. Her descriptions of the conditions in the middle of the last century are illuminating, when "medical rubbing" was a disreputable feature of the social life of that period. Under the influence of Weir Mitchell and of the Swedish School the new Society of Trained Masseuses was conceived at a time when the emancipation of women released a large number of cultivated and intelligent women of the right type looking for a career outside their own homes. An examination paper for obtaining the certificate of the Society is of some interest as an indication of the desire to place the training on a scientific basis: "Describe the circulation of the blood" is quite a broad question for a would-be masseuse of 1895.

From "medical rubbing" the training of the masseuse has had to be expanded to include the use of all the modern paraphernalia of physiotherapy in a relatively short period—the complexities of medical electricity as well as the far more ancient art of hydrotherapy. Perhaps Miss Wicksteed is more concerned with the administrative and medico-political aspects

of the relations of the society with the medical profession, however, than with stressing the continued need for a scientific and critical approach to these techniques.

It is satisfactory, as she so rightly points out, that the presidents during the past twenty years have all been outstanding members of the medical profession. It is a pity that she has not been able to discuss the tremendous significance of the National Health Service Act, whether for good or ill, with its effect on the public, or State, demand for physiotherapy to become more widely available. Perhaps in a second edition the situation can be brought up to date. But there is no doubt that all those, whether medical or lay, concerned with the organization of the care of patients requiring physiotherapy at the present time will have a wider appreciation of this important aspect of treatment when they have read the book.

W. S. C. COPEMAN.

DISEASES OF THE EYE

Lehrbuch der Augenheilkunde. Edited by M. Amsler, A. Brückner, A. Franceschetti, H. Goldman, and E. B. Streiff. (Pp. 858; 342 figures. 85 Swiss francs.) Basle: Verlag Von S. Karger.

This volume on diseases of the eye, edited by the occupants of the five chairs of ophthalmology in Switzerland, arose out of the need of a textbook on the subject during the war, when books from abroad were not readily available. Swiss ophthalmology is of high quality, and the fortuitous circumstances which led to the production of this book are an unnecessary excuse for its appearance. The eighteen contributors, with the exception of Professor Weve, are all Swiss. The book is beautifully produced, and even if it broke no new ground it would have been a welcome addition to the literature on ophthalmology.

Most of the subject matter is presented in the way usual to textbooks. A completely modern book would reflect the three formative influences which are remoulding present-day ophthalmology—fuller appreciation of physiological principles, a better understanding of the significance of genetics in ophthalmology, and the imperceptible changes in pathological conceptions consequent on the therapeutic revolution experienced during the past decade. The first two of these influences are strongly reflected in the present text. The chapters on the physiology of the eye by Professor A. Brückner, Dr. R. Brückner, and H. Sillmann, as also the general tone of the account, do full justice to the considerable recent developments in ocular physiology and their bearing on diseases of the eye. The extensive chapter on heredity in relation to the eye by Professor Franceschetti and Dr. Klein likewise reflects satisfactorily the developments in genetics. However, the text is less satisfactory in revealing the changes in our conceptions of pathology. The distinction between infection and inflammation, though recognized, is hardly sufficiently emphasized. There is therefore some confusion on the possibilities of modern therapeutics, and undue prominence is given to methods of treatment that might well be rejected. None the less this book is the best short exposition available of present-day ophthalmology. Unlike many collective works, the text reads smoothly and is devoid of redundancies and overlapping.

ARNOLD SORSBY.

PSYCHOPATHOLOGY

Clinical Studies in Psychopathology. A Contribution to the Aetiology of Neurotic Illness. By Henry V. Dicks, M.A., M.D., F.R.C.P. Second edition. (Pp. 238. 15s.) London: Edward Arnold, 1947.

The second edition of Professor Dicks's book has no major changes and its success will be as assured as that of the first. As the title indicates, it is not a systematic presentation of psychopathology but a collection of case studies illustrating the author's views on some of the chief manifestations of the psychoneuroses. Professor Dicks takes his main inspiration from the work of the psychoanalysts, to whom he makes generous acknowledgment although not belonging officially to their group. Indeed, the brevity of the present work—one of its many attractive features—is chiefly due to the assumption that the reader has a general knowledge of the basic psychopathological theories of Freud and his school. The author's main

contribution consists in a greater emphasis than that given, he thinks, by the psycho-analysts on the conflicts at the early oral phases of development. He suggests that there are three biological needs—a self-preservative tendency, a sexual tendency (Freud's libido), and aggressiveness—and suggests that it is the self-preservative tendency that has to be satisfied by adequate feelings of security in the infant's earliest relations with its mother. When this security is absent the result is anxieties which can have great effects on the future growth of the personality. He also suggests that Freud's libido theory does not do justice to the full instinctual forces that enter into love relationships at all ages, a particularly important omission being the role of tender as distinct from sensual elements.

In the main text the author appears to take psycho-analytic views as much more definite and "official" than they are. Thus the work of Mrs. Klein and other psycho-analysts of the English school on the earliest stages of psychic development has met several of the points raised against Freud's earlier views. (In the preface to this edition, however, the author appears to have recognized this as an omission he would like to make good in any more comprehensive re-writing.) He makes many other interesting theoretical suggestions, and, although primarily for the psychotherapist, the cases are described so clearly that even the tyro in this field cannot fail to get a vivid impression of the psychological forces underlying neurotic illness.

J. D. SUTHERLAND.

REFORM OF MENTAL HOSPITALS

That Which is Caesar's. By H. G. Woodley. (Pp. 158. 8s. 6d.) Oxford: Pen-in-Hand, St. Michael's Street.

No doubt there is a good case for the reform of institutional psychiatry. In a civilized and prosperous country the practice of herding thousands of certified patients in huge compounds can scarcely be justified. With a decentralized system, and the services of five, or preferably ten, thousand suitably trained psychiatrists, it would no doubt be possible to treat the certified population of Great Britain in a way which might satisfy the author of this book. But to judge from his own presentation there appears to be grave doubt whether the case for reform can be stated either temperately or effectively by someone who has spent a year in a mental institution as a certified patient.

Outraged by the circumstances of his certification, and horrified both by the routines of treatment and by what he regards as a glaring lack of individual psychological attention, Mr. Woodley came to the conclusion that the only way to bring all this home to the public was to employ shock tactics, using for this purpose a scriptural variety of journalese which is certain to alienate the fastidious and to arouse suspicion in the minds of professionally trained persons. This is the more regrettable since the author has quite clearly grasped the desirability of maintaining whatever rapport is possible with even advanced or deteriorated cases, an understanding which he has evidently fortified with some reading in clinical psychology. Apparently, however, his reading has been vitiated by a persistent bias in favour of exclusively environmental causes of insanity. He is consequently altogether too optimistic about the accessibility of the psychoses even to the most understanding treatment. In fact the main virtue of the book is that the author attempts, however unsuccessfully, to do what would be much better done by psychiatrists themselves, if only they were so disposed.

EDWARD GLOVER.

Volume 2 of *Advances in Internal Medicine*, edited by Dr. William Dock and Dr. I. Snapper (Interscience Publishers, £2 17s.), contains a series of reviews by first-rate authors on clinical subjects where there have recently been considerable advances. The articles vary from about 5,000 to 20,000 words in length and cover a wide field. The ones of greatest interest to the reviewer, who is not a cardiologist, were "Circulatory Failure Studied by means of Venous Catheterization" (McMichael), "Angiocardiography" (Sussman and Grishman), and "Surgical Treatment of Hypertension" (Grimson). These provide the ordinary consulting physician or clinical lecturer with an admirably clear picture of the present situation. The article on angiocardiography is illustrated by remarkably fine x-ray photographs. Anyone looking for up-to-date accounts of disease and its treatment will now have to keep an eye on *Advances in Internal Medicine*.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

An Atlas of Traumatic Surgery. By Joseph Trueta, M.D., D.Sc., F.R.C.S. Can. (Pp. 150. 30s.) Oxford: Blackwell Scientific Publications. 1949.

A short, fully illustrated volume.

A Textbook of Pathology, General and Special. By J. M. Beattie, M.A., M.D., D.Sc., and W. E. C. Dickson, M.D., B.Sc., F.R.C.P. Ed. Vols. 1 and 2. 5th ed. (Pp. 1,582. 168s.) London: William Heinemann. 1948.

Revised and enlarged

The Thyroid and its Diseases. By J. H. Means, M.D. 2nd ed. (Pp. 571. 72s.) London: J. B. Lippincott. 1948.

From the Thyroid Clinic of the Massachusetts General Hospital.

Ways to Better Hearing. By L. Brentano. (Pp. 212. 10s. 6d.) London: George Allen and Unwin. 1948.

For the deaf.

Management of Common Gastro-Intestinal Diseases. Edited by T. A. Johnson. (Pp. 280. 42s.) London: Lippincott. 1948.

From the American Practitioner series.

Taylor's Principles and Practice of Medical Jurisprudence. Edited by Sir S. Smith, C.B.E., M.D., F.R.C.P., D.P.H. Vol. 2. 10th ed. (Pp. 841. 50s.) London: J. and A. Churchill. 1948.

Considerably revised.

Surface and Radiological Anatomy. By A. B. Appleton, M.A., M.D., and others. 3rd ed. (Pp. 332. 35s.) Cambridge: W. Heffer. 1949.

For students and general practitioners.

British Surgical Practice. Edited by Sir E. Rock Carling, F.R.C.S., F.R.C.P., and J. P. Ross, M.S., F.R.C.S. Vol. 5. (Pp. 494. 60s.) London: Butterworth. 1948.

This volume contains the section Hodgkin's Disease—Lymphogranuloma.

Bacterial and Mycotic Infections of Man. Edited by R. J. Dubos, Ph.D. (Pp. 785. 45s.) London: J. B. Lippincott. 1948.

For medical students.

Handbook of Midwifery. By M. Puxon, M.D., M.R.C.O.G. (Pp. 326. 25s.) London: Sylvio Publications. 1949.

For general practitioners and students preparing for qualifying and higher examinations.

Technic of Medication. By A. Smith, M.D., C.M., M.Sc. (Pp. 255. 30s.) London: J. B. Lippincott. 1948.

A brief guide to practical therapeutics.

Practical Aspects of Thyroid Disease. By G. Crile, jun., M.D., F.A.C.S. (Pp. 355. 30s.) London: W. B. Saunders. 1949.

A short volume for physicians and surgeons.

Refraction of the Eye. By A. Cowan, M.D. 3rd ed. (Pp. 287. 27s. 6d.) London: Henry Kimpton. 1948.

The third edition has been revised and brought up to date.

Obstetric Analgesia and Anesthesia. By F. F. Snyder, M.D. (Pp. 401. 32s. 6d.) London: W. B. Saunders. 1949.

Includes a large section on respiratory accidents to the child.

Irish Medical Directory and Hospital Yearbook, 1948-9. 10th ed. (Pp. 404. 15s. 6d.) Dublin: The Parkside Press. 1949.

The Scientific Paper. By S. F. Trelease. (Pp. 152. 11s.) London: Baillière, Tindall and Cox. 1947

A short guide for research workers.

Essentials of Dermatology. By N. Tobias, M.D. 3rd ed. (Pp. 518. 36s.) London: J. B. Lippincott. 1948.

A short account for students and practitioners.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 30 1949

BREACH OF FAITH

Ever since the profession agreed to enter the Health Service and to work it as successfully as the administration would allow, it has assumed that the Government would meet its just claims for adequate remuneration. Both general practitioners and the Government have accepted the recommendations of the Spens Committee. The Report on Remuneration prepared by the General Medical Services Committee,¹ which was approved by the Conference of Representatives of Local Medical Committees on March 3 and received the fullest support of the Representative Body on March 29, gave cogent reasons for believing that the remuneration of general practitioners is inadequate, since the central pool is too small. The report has been in the hands of the Ministry since March 4, and a deputation of members of the General Medical Services Committee went to the Ministry on April 14 prepared to discuss remuneration in the light of the report. At that meeting the Ministry refused to consider the document until it had obtained and studied returns from executive councils showing the exact amounts paid to practitioners on their lists. At the same meeting an issue was raised—almost incidentally—of much deeper importance. When the Ministry was asked whether, in the event of a dispute on remuneration, the profession's claims could be submitted through Whitley machinery and finally, if necessary, to arbitration, the reply given was as follows: "It must not be assumed without further discussion that participation in the Whitley machinery necessarily involves, in the event of disagreement, the right to resort compulsorily to arbitration on all subjects." The profession will be disturbed at the negative caution of this reply.

Without the right to resort compulsorily to arbitration on a subject such as remuneration the Whitley machinery may well be reduced to mere trifling, the correction of minor administrative errors here and there and the removal of the occasional straw from the camel's back. It is difficult to see how any claims on which the two sides of the Whitley Council fail to agree can be justly decided if, on the Government's prerogative, resort to independent arbitration is denied. Indeed, not only the claim but justice itself would be denied. The profession would lie at the mercy of any Government in power and might have no other course to take but that which it has always most disliked and regarded as a last resort—refusal to work the Service or some part of it.

Some evidence of the Government's assurances was given by the Secretary of the Association last week,² and he

made this comment: "To withdraw the promise of automatic arbitration in the event of disagreement on matters of remuneration would be a breach of many undertakings, a departure from modern negotiating practice, and potentially dangerous to the profession." The Chairman of Council said³ at the Special Representative Meeting on May 28, 1948: "The Minister has agreed that when the Service starts on July 5 we can immediately raise with the Whitley Council which will be set up to consider general-practitioner remuneration this matter of the betterment factor and the implementation of the Spens Report. Therefore we are not bound to the present conditions as set out in the remuneration offer if we can prove to the Whitley Council that the amount is not the proper one." Nobody then supposed it to be the Minister's conception of Whitley machinery that a claim should be submitted to it and then, in the event of disagreement, left unsettled or determined arbitrarily by the Minister himself. The assumption that the profession's claims would be justly met was a prime factor influencing doctors to co-operate in working the Service, and a refusal to have them submitted to arbitration would be, as the General Medical Services Committee recorded last week, a gross breach of faith. The formation of the British Medical Guild is therefore particularly opportune, and, fully supported by the profession, it will provide them with a much-needed source of strength.

The profession will be surprised to learn that more than nine months after the Service started the Ministry does not know how many effective principals are on executive councils' lists. It declines to discuss the general practitioners' claims until it has gathered and analysed the information from the executive councils, which it hopes to have done by the middle of May. This delay is particularly remiss because the Ministry's estimate of public money paid out falls considerably short of the profession's moderate demands, which are based on the betterment factor of 170 to take account of the increased cost of living since 1939. The Ministry could surely have consented to begin discussions on the general merits of the case apart from its details. The deputation was further dissatisfied to learn on April 14 that the Ministry could give no assurance that there would be an addition to the pool on account of the increased number of general practitioners in the Service, and that, if remuneration is improved, the increase will not necessarily be retrospective to July 5, 1948. Since there have always been considerably more than 17,900 general practitioners in the Service—the estimate on which the size of the central pool was originally based—refusal to make the increase retrospective to July 5, 1948, when the necessity for it now is clear, would be a grave injustice.

Government spokesmen have admitted that there are grounds for general practitioners' being dissatisfied with their remuneration. On Jan. 21 Mr. Messer said in the House of Commons, "Clearly everybody knows that the situation cannot remain as it is." The profession knows that well; the Minister's further delay in acknowledging it and his lack of assurance that pay would be adjusted for the first nine months of the Service are in lamentable contrast to the speed with which he acted, without carrying out a full inquiry, to cut the remuneration of the ophthalmic medical practitioners.

AUREOMYCIN

We have already referred¹ to the preliminary account by Bryer and his colleagues² of the new antibiotic aureomycin or, as it is sometimes termed, duomycin. Further information is now available. Like chloramphenicol (chloromycetin), aureomycin is produced by a new member of the genus *Streptomyces*, for which the name *Streptomyces aureofaciens* n. sp. is proposed. There are a number of species included under the category of "yellow" streptomycetes and most of them are soil inhabitants. The antibiotic aureomycin is a crystalline powder and is dispensed in the form of a yellow hydrochloride. The salt is soluble in distilled water and in 5% glucose in distilled water: solutions in normal saline precipitate when a concentration greater than 1% of the drug is reached. The powder is stable at room temperature, and in aqueous solution at pH 4.0 no loss of potency occurs after two weeks at 4° C. If the solution is neutralized or rendered alkaline the loss of activity is rapid. Aureomycin is not adsorbed by filters which retain bacteria.³

When injected intramuscularly solutions of aureomycin in distilled water or glucose cause acute pain lasting for some minutes, followed by a dull pain which may continue for half an hour, even if the drug is dissolved in 1% procaine: with repeated administration the sites of injection become red and tender. Intramuscular medication in man is thus hardly feasible, but fortunately aureomycin is well tolerated and active by mouth. A single dose of 0.5 g. of a crude preparation caused a loss of appetite and nausea, but these symptoms occur only rarely after the administration of more purified preparations in gelatin capsules: they are entirely absent if $\frac{1}{2}$ oz. (15 g.) of colloidal aluminium hydroxide is given with each 100 mg. of the drug. In this way a dose of 100 mg. has been given without any signs of toxicity every two hours to a patient who weighed 40 kg. Difficulty in determining concentrations of the drug in serum or plasma has been reported: loss of activity occurs on incubation at 37° C., serum proteins have a neutralizing effect, and a relatively high concentration of the antibiotic is necessary for minimal inhibition of growth of the test organism, *Klebsiella pneumoniae* type A. Some observers⁴ prefer a strain of *Bacillus cereus* var. *mycoides* as the test organism, others¹¹ the strain of *Bacillus subtilis* 219 which is used in the assay of streptomycin, or a haemolytic streptococcus. A level of 0.6 μ g. per ml. of serum is the lowest concentration of drug that can be measured with *K. pneumoniae*. This concentration is obtained by an oral dose of

0.5 g. and an intramuscular injection of 40 mg.: after oral administration alone repeated doses of 1 g. every six hours give detectable amounts in the blood—about 2 μ g. per ml. Aureomycin appears rapidly in the urine, and excretion continues for two to three days after a single oral dose of 0.5 g. In adults given repeated oral doses of 1 to 2 g. daily concentrations up to 256 μ g. per ml. may be found in the urine. After intravenous injection aureomycin passes into the cerebrospinal fluid.

The antibiotic range of aureomycin is a wide one and has been studied by a number of observers.⁷⁻¹¹ Pneumococci, gonococci, meningococci, and *Streptococcus pyogenes* are all inhibited by 1 μ g. or less of aureomycin per ml. Staphylococci and most strains of Gram-negative bacilli, including species of salmonella, are inhibited by concentrations varying from 1 to 25 μ g. per ml. Strains of two species, *Proteus vulgaris* and *Pseudomonas aeruginosa*, are moderately resistant, requiring from 125 to 250 μ g. per ml. for complete inhibition. There is no cross resistance with penicillin- and streptomycin-resistant strains, nor with strains that have become resistant to polymyxin or bacitracin. Resistance to aureomycin is difficult to produce either *in vivo* or *in vitro*. Some increase in resistance, however, has been induced against *Proteus vulgaris*, *Pseudomonas aeruginosa*, and *Bacterium coli*: such aureomycin-resistant strains do not produce any aureomycin-inhibiting substance corresponding to penicillinase. In experimental animals the toxicity is very low: mice tolerated by mouth 1,500 mg. and rats 3,000 mg. per kg. of body weight.

Accounts of the treatment of numerous human infections with aureomycin have now been published. Collins and his colleagues¹² reported the results obtained in 66 cases of gonorrhoea: only six failed to respond, and these had been given treatment for one day with a total of only 1.0 or 1.5 g. of aureomycin. Pneumococcal pneumonia has been successfully treated with 0.5 g. every six or eight hours, the total doses being from 10 to 20 g. Good results have also been obtained in meningococcal septicaemia. Claims have been made for the curative action of aureomycin in brucella infections: but in view of the difficulties in assessing the true value of any drug in these infections further controlled studies are required. In bacteraemia due to *Bacterium coli* and in salmonella infections aureomycin has failed: in the treatment of typhoid and paratyphoid it is thus inferior to chloramphenicol (chloromycetin). On the other hand Wright and his colleagues¹³ have shown that granuloma inguinale is readily controlled by aureomycin, and in view of its low toxicity it may well prove superior to streptomycin. The chemotherapeutic activities of aureomycin are not restricted to bacteria. Wong and Cox,¹⁴ as well as Wright and his associates,¹⁵ have shown that aureomycin has an effect on the viruses of lymphogranuloma venereum and psittacosis and also on rickettsial infections, including epidemic and murine typhus, scrub typhus, Rocky Mountain spotted fever, Q fever, and rickettsialpox.¹⁴⁻¹⁶ There is also some evidence that non-specific urethritis can be controlled by aureomycin. Finally, Braley and Sanders¹⁷ have reported on the use of a 0.5% solution of a borated salt of aureomycin in 100 patients with conjunctival and corneal infections. This was very effective in coccal infections, and

difficult to reduce the bacterial count on standard agar to less than 500 bacteria per millilitre and to secure the absence of coliform bacilli from 1 ml. The cost should be about a penny for 200 glasses.

Shortage of glasses, space, and assistance makes the ideal of a clean, dry, sterile glass for each customer impracticable, but a step in the right direction can be made if the results of the investigations referred to are sensibly applied. Finally, a word might be said about the bartender's towel. If it cannot be abolished it should be frequently changed, and used solely for glasses which have been treated with antiseptic.

THE RELIABILITY OF LABORATORY TESTS

If a decision is to be based on or influenced to any extent by a laboratory test, then it follows that the result obtained must be precise and that the test should not be so complex that many possible sources of error are present. Belk and Sunderman¹ have checked the accuracy of the results of some common chemical measurements made in hospitals throughout the State of Pennsylvania. The 59 laboratories co-operating in the investigation were asked to analyse the following: solutions of glucose, sodium chloride, urea, and calcium (in concentrations similar to that found in human blood); serum for the measurement of total protein, albumin, and globulin; and citrated whole blood for the estimation of haemoglobin concentration. The figures received from the laboratories were surprisingly inaccurate. The results were grouped by the referees into three categories—satisfactory, unsatisfactory, and gross error. The sodium chloride analysis was done best—68% of the results being satisfactory. The albumin estimation was the worst—20% being satisfactory, 64% unsatisfactory, and 16% having a gross error. A questionnaire was sent to 95 pathologists in order to obtain their explanation for such unreliable results, and they included the following as contributory factors: (1) poorly trained technicians (in 82 answers); (2) inadequate number of technicians (in 80 answers); (3) lack of understanding between pathologist and staff (in 64 answers); (4) poor equipment (in 63 answers); and (5) insufficient floor space (in 57 answers).

In this country Biggs and MacMillan² have assessed the accuracy of some common haematological methods used in routine laboratory work. These included: haemoglobin estimation, red cell count, and packed cell volume (from which errors in estimating the colour index, mean corpuscular volume, and mean corpuscular haemoglobin concentration could be calculated); mean cell diameter derived from the Price-Jones curve; reticulocyte count; platelet count; whole-blood coagulation; and red-cell fragility. The white cell count was not included, because it is widely recognized that this has a large error. The results obtained in these tests by laboratory technicians and doctors were analysed in detail. As might be expected, the disagreement between observers was an important source of error. For some of the variables the variation around the mean value was large, and it was evident that some tests cannot be expected to measure small differences reliably. The red-cell count had an "intrinsic" error, and thus the colour index and mean corpuscular volume were unreliable. The platelet count was also unreliable, and thus the platelet fragility test was unreliable. The results of the streptomycin resistance test were reliable. In the three other cases in which clodocyte counts were obtained during treatment no significant rise in platelet resistance was shown after 6, 15, and 30 days. Of the surviving cases, five out of six showed a significant rise in platelet resistance.

the reliability of routine work will follow the selection of those methods which give the best results in the hands of the average laboratory worker." If the results of any test are to be of value to the clinician, then the test must be able to detect differences smaller than those which are of clinical significance. It seems that not all laboratory tests meet this requirement, for some of them demand more skill than the average laboratory technician possesses.

MELANOMA OF THE CHOROID

In a series of papers from 1931 to 1942 Callender and his associates in the U.S.A. stressed the significance of reticulin in the prognosis of melanomas of the choroid. The richer the reticulin content the better they found the prognosis to be. They also held that prognosis could clearly be assessed by the cell type: the lowest mortality was in the group of cases with spindle-cell A tumours; it was considerably higher with spindle-cell B, and highest with epithelioid tumours. The importance of the melanin content as a prognostic aid was not so marked, though the mortality was higher in the group of cases in which the pigment content of the tumours was classed as heavy. Callender's method of classification has proved of value, and is confirmed in broad outline by Benjamin, Cumings, Goldsmith, and Sorsby¹ in a study of 250 cases of melanoma of the choroid. Their statistical assessment, however, does not confirm Callender's results in detail. In the first place they found a much better prognosis—a survival rate of 80.7% in a period of five years in their series, against 52% in that of Callender. The discrepancy in survival rates is still more noticeable if a period of 10 years is considered, the respective rates being 73.4% and 34.0%. Again, while Callender was able to grade mortality in relation to each of the cell types, melanin content, and reticulin content, the British workers obtained a more distinctly limited relationship. The only statistically significant findings they could extract were an increased mortality in the group of cases with epithelioid-cell tumours, a lower mortality in cases where the pigment content of the tumours was classed as light, and a higher mortality when the reticulin content was low. In criticizing assessment of mortality they rightly point out the need to take into account macroscopic features such as vascularity, haemorrhage, necrosis, and above all extension beyond the uvea.

Melanomata of the choroid are puzzling tumours. The high survival rate in this condition is probably unique in cancer statistics. It is difficult to grade the tumours owing to their histological complexity, and their relationship to melanomata elsewhere in the body is not readily assessed. On the one hand it has been suggested that the tumours are of mesodermal origin, on the other that they are of ectodermal origin. These complexities are discussed fully by Reese,² who attempts to sort out three distinct varieties of choroidal melanoma. Two varieties he considers to be neurogenic in origin; these are the tumours arising from the Schwann cell and the naevus cell, and the tumours arising from the pigment epithelium of the retina and ciliary body. These two varieties are therefore not strictly speaking choroidal tumours at all. The third group he regards as mesodermal in origin—chromatogenic melanoma arising from the uveal tract. His classification is largely a compromise between the conflicting hypotheses of ectodermal and mesodermal origin of choroidal tumours, and it would gain more ready acceptance if it could be shown to possess a prognostic significance.

ANOPHELES ERADICATION IN CYPRUS

BY

HORACE SHELLEY, F.R.F.P.S., M.R.C.P., D.T.M.&H.

Director of Medical and Health Services, Cyprus

AND

MEHMED AZIZ, M.B.E., As.R.S.I.

Executive Officer, Anopheles Eradication Scheme, Cyprus

The history of the malarial fevers in Cyprus has been long and tragic, and over the centuries these fevers have cost the island much in human life and have been the major cause of chronic ill-health and invalidism. It is on record that "fevers and bad air" were a source of much trouble in the year 1394, and in a letter written by Namik Kemal, who was a Turkish poet of national reputation, a few years before the British occupation of the island in 1878 it is stated that "the hum of noxious pests sounds like that of the most modern weapons, and the diseases, the mildest of which is fever, are capable of killing a person much quicker than bullets." In the early days of occupation the British Army suffered severely from malaria, and steps were taken to reduce the breeding places of mosquitoes by draining and filling of swamps and planting of trees, particularly in the vicinity of the main towns. These operations brought some improvement, but the villages remained open to the same menace as previously.

In the year 1900 the District Medical Officer, Larnaca, Dr. G. A. Williamson, discovered malaria parasites in the blood of 470 out of 503 patients diagnosed clinically as cases of malaria; infestations were divided almost equally between *Plasmodium falciparum* and *P. vivax*, plus an occasional *P. malariae*. The three main species of parasite were thus proved to be present in the island. During 1912 the High Commissioner, Sir Hamilton Goold-Adams, informed the Secretary of State that he had recently ascertained the widespread prevalence of malarial fever in the inhabitants of the island, and that, though steps had been taken by Government to combat the menace, he considered that more could be done, and requested that an expert malariologist be sent to Cyprus to study the disease and advise concerning necessary preventive measures. In reply to this request Sir Ronald Ross visited the island in 1913 and found that 25.4% of the children had splenic enlargement. On his recommendation certain marshes were drained and a special staff was trained to undertake mosquito-control work. These drainage works were carried out in various places which were ideal breeding-centres for *Anopheles elutus*, a known vector of malaria. It was noted that coincident with these measures the incidence of enlarged spleen and active cases of malaria underwent a great diminution, and conditions remained apparently much improved until after the 1914-18 war, when they rapidly deteriorated for various causes and remained unsatisfactory until the beginning of the Anopheles Eradication Campaign in 1946.

There were three principal vectors of malaria in Cyprus: *A. superpictus*, breeding in shallow collections of water exposed to full sunlight; *A. elutus*, breeding in temporary collections and marshy collections of water; and *A. birfurcatus*, breeding in heavily shaded and cool water, including both wells and surface collections.

In 1935 Dr. Barber, of the International Health Division, Rockefeller Foundation, found a parasite incidence of 70% in certain village children, and sickness due to malaria at times assumed almost epidemic proportions. Careful dissections of *A. superpictus* indicated a sporozoite rate seven times greater than that of *A. gambiae* in certain malarial regions in Africa.

From the above information it is obvious that the problem of anopheles eradication in Cyprus was both complicated and urgent; nevertheless Dr. R. E. Cheverton, a former Director of Medical Services in the island, strongly believed in the possibility of obtaining the total eradication of anopheles vectors of malaria, and he therefore arranged for one of us (M.A.) to visit Egypt in 1945 and to study the campaign for the eradication of *A. gambiae* being carried out in the Nile Valley. Later Dr. F. L. Soper, of the Rockefeller Foundation,

visited Cyprus and expressed the view that there was every possibility of eradicating the anopheles from the island.

In 1946, working on this basic advice, an experimental area was chosen about 500 square miles (1,295 km.²) in extent and the species eradication carried out with vigour and with complete success; it was thus considered justifiable to extend the campaign to the whole island. Funds for the experimental work in 1946 came from the Colonial Development and Welfare Scheme. It was estimated that £310,000 would be the approximate cost of securing island-wide freedom from anopheles vectors.

Organization of Campaign

After the preliminary selection and training of staff and a comprehensive survey of breeding-places the island was divided into six districts, subdivided into 39 sections, 111 zones, and 556 blocks. One block was the area which could be covered by one man in twelve working days. A group of blocks constituted a zone under a zone officer, and a group of zones constituted a section under a section officer. Each section officer was assisted by special checkers of larvae and adult mosquitoes. Each district was under the direct administration of headquarters through the medium of the district officer, and in order that close and accurate supervision could be maintained the executive officer had under his immediate direction independent checkers, who could be sent to any district, section, zone, or block as considered advisable.

The executive officer (M.A.) was in entire charge of the whole operation, including the purchase and issue of stores, equipment, and larvicides, and the maintenance of records, and it was only necessary for him to approach the Director of Medical and Health Services in case of difficulties necessitating extra assistance and advice and to report progress.

The larvicides used during most of the campaign consisted of a 3 to 4% solution of D.D.T. in gas oil. "Malarion," Paris green, and simple fuel oil were used on certain occasions, and during 1948-9 D.D.T. and gammexane smoke were utilized in the case of buildings with high ceilings and in certain inaccessible places. Major drainage schemes were not attempted, though several marshy areas exist. Spraying was carried out with locally made or imported "flit guns," preference being given to those with a long handle.

The campaign proper started in April, 1946, with a direct attack on all breeding-places, the results being noted with particular care and the presence of one larva being sufficient to declare a block still positive. A protective zone about ten miles wide, situated between the eradication area and the rest of the island, was subjected to intense mosquito control with the object of preventing any reinfestation of the eradication area. During the winter months of 1946-7, and also in subsequent years, hibernating adult anopheles were attacked by subjecting all human and animal shelters to light treatment with D.D.T., the object being to destroy any adults and thus reduce the possibility of any widespread breeding in March and the later months.

It has to be appreciated that, as not all species of anopheles in Cyprus are necessarily frequenters of houses, search and attack had to be made in caves, both natural and artificial, tombs, tree trunks, etc., and checking could not be limited to villages and other settlements but had to extend over every part of the island. This needed both courage and ingenuity on the part of those concerned, who had on occasion to be lowered by ropes to deal with breeding- or sheltering-places which could be approached only from the perpendicular heights of cliffs or mountains.

Results

The effect of the campaign on the incidence of malaria has been remarkable. During 1944, two years previous to the opening of the scheme, 7,686 cases were reported, and this figure was reduced during 1948 to 406, of which number only three were considered to be recent infections.

In 1944 the percentages of school-children examined who had splenomegaly and parasitaemia were 32.4 and 51.9 respectively, figures which by 1948 had fallen to 10.6 and 1.3 respectively. In 1948 blood films from 655 infants (under 2 years) living in formerly highly malarious villages were examined and found negative for parasites.

At the time of writing this account not a single anopheles larva or adult had been discovered in the whole island for thirteen weeks, and it is anticipated that, apart from maintenance work, the campaign proper will end within two months.

It is not possible in a brief article to detail the numerous and unexpected difficulties which were encountered. At one stage the political situation in the Near East caused an interruption in the regular supply of oil, which for a period had serious repercussions on the task in hand. Delays also occurred in the receipt of essential larvicides and other items, but fortunately these difficulties were gradually overcome.

Our grateful thanks are due to Professor G. Macdonald, Director of the Ross Institute of Tropical Hygiene, London, for his advice, criticism, and assistance; to Drs. L. Soper and Bruce Wilson, of the Rockefeller Foundation, for their great help in the initial stages; to Dr J. R. Busvine for his independent and confirmatory checking during 1948; and finally to all those who have given assistance and encouragement.

THE RED CROSS UNDER REVISION

[FROM OUR CORRESPONDENT IN GENEVA]

A diplomatic conference for the establishment of new international conventions for the protection of war victims was opened in Geneva on April 21, and is expected to last for six weeks. Forty-five States, including Soviet Russia and the Vatican, are participating. The United Kingdom delegation is headed by Sir Robert Craigie and consists of representatives of the War Office, Admiralty, Ministry of Transport, Home Office, and Foreign Office. Several international organizations, including WHO, are observers. The first meeting was held at the Hotel de Ville, in the same room in which the Red Cross was established in the middle of the last century.

Three draft conventions are under consideration. Two of them, for the relief of the wounded and sick in the armed forces in the field and for the treatment of prisoners of war, are proposed revisions of the conventions concluded at Geneva in 1929. The third is a convention for the protection of civilians in time of war. All three were considered at the eighteenth International Red Cross Conference held recently at Stockholm, and now they are being critically reviewed by the representatives of Governments.

Already the United Kingdom delegation has put forward some criticisms of the International Red Cross proposals. It has suggested that certain passages in the draft convention for the relief of the wounded and sick, while appropriate to the circumstances of war as it was waged in the middle of the nineteenth century, bear no evident relation to the conditions of war usual in the middle of the twentieth century. The International Red Cross, in the view of the British delegation, appears to consider that all those who are charged with caring for the wounded and sick are outside the combatant forces altogether and can therefore be regarded as neutrals in any conflict. In fact medical services now form an integral and necessary part of the whole fighting machine, and their primary purpose is to ensure the fitness of combatant personnel to carry on the conflict. Here, of course, there is a distinction between the medical services of an army and of a humanitarian organization like the Red Cross. "The United Kingdom Government recognizes that, in the presence of wounded and sick, medical personnel should behave in the tradition of the Red Cross and should treat without distinction, except on grounds of need, the personnel of their own forces and those of the enemy." But the delegation goes on to urge that this fact should not be allowed to obscure the fundamental change which has taken place since the Red Cross emblem first appeared on the battlefield—namely, that the medical services of military forces are now organized with positive duties designed to maintain and increase the fighting efficiency of such forces. It presses strongly the view that all personnel, whether "protected" or not, falling into the hands of an adverse belligerent should be prisoners of war; that among prisoners of war all those required to care for the sick and wounded in the hands of the enemy should have the necessary freedom and facilities for carrying out their work, and that surplus doctors and nurses should be repatriated.

The draft convention for the protection of civilians in time of war is a document of 140 articles. It deals largely with the care of internees. It is laid down that every place of internment must have an adequate infirmary under the direction of a qualified doctor. Isolation wards must be set aside for contagious disease. Where special treatment, surgical operation, or hospital care is necessary, internees must be admitted to institutions where such treatment is given, and the care they receive must not be inferior to that provided for the general population. Internees, says one article, shall have the attention preferably of medical men or women of their own nationality. The costs of treatment, including those of any apparatus necessary for the maintenance of internees in good health, particularly dentures and other prostheses, and spectacles, shall be borne by the detaining power. Medical inspections of internees are to be made at least once a month, with the object of supervising their general health, nutrition, and cleanliness, and detecting contagious diseases, especially tuberculosis, malaria, and venereal conditions. These inspections are to include, wherever possible, periodical radiological examination and checking of weight. It is also provided that international standards of nutrition may be applied to the quantity, quality, and variety of food for internees, with additional food for expectant and nursing mothers and children.

This important conference has hardly yet got into its stride. The first days, as is usual in these big international assemblies, were frittered away over exasperating points on procedure, objections, validity of credentials, and admission of observers.

A HEALTH SERVICE FOR CHILDREN

CHADWICK PUBLIC LECTURE

A lecture under the auspices of the Chadwick Trust was delivered at Westminster Hospital Medical School on March 22 by Dr. HELEN MACKAY.

Dr. Mackay said that a hundred years ago there were no children's hospitals in this country and general hospitals discouraged the admission of children; half the inmates of work-houses were children. Eighty years ago the forerunners of infant-welfare centres made their appearance, but not until 1924 was the first chair in paediatrics established. Nowadays every child had a doctor, but there were still some deficiencies in the service. Undergraduates received a minimum of training in child care, and were often in difficulties when confronted with the sick child. Before last July doctors in most clinics could treat minor ailments. Now, in many areas they had to say that they were not allowed to do so, and the mother must take the sick baby to some overcrowded surgery or outpatient department. School medical work varied in different areas, some school doctors showing initiative, others being tied up by regulations which were not to the benefit of the child. In many hospitals there was no specially trained nurse in charge of the children's ward; in others children were scattered throughout the wards for adults; and in some hospitals wards were overcrowded with children who could have been nursed at home. The selection of cases for hospital should be controlled by doctors with experience of paediatrics.

The first essential in planning a health service for children was a well-trained staff with good facilities working as a team. A few fairly large hospitals were more economical in staff than numerous small ones. It was important to build up a small number of really adequate hospital units as quickly as the financial position allowed. Each region should have an overall plan, and the people on the spot must get together not only on principle but on detail. It was important also that the general practitioner should have adequate paediatric training. A large part of the clinical work in schools and welfare centres should be done by general practitioners interested in paediatrics, their numbers being augmented by those who took service as child-welfare and school medical officers.

Hospital Planning

The hospital service, Dr. Mackay continued, should have paediatric units in large hospitals, and regional centres for teaching and research. In most hospital areas the paediatric

unit would have beds in one hospital, and if a management committee area did not contain such a unit it should have a branch paediatric out-patient department based on a unit elsewhere. Beds should be provided for nursing mothers, and all in-patient children under puberty should be dealt with in the children's department. Beds for neonatal cases should be under the direction of one or two paediatricians, one of whom might be the children's health officer. As soon as a unit could function in isolation it must be provided with the services of all the necessary specialists and sub-departments. Units should not be too small, and they should be so sited as to make the best possible use of existing facilities, which should be within reasonable travelling distance from every part of the region.

Dr. Mackay also pleaded for paediatric regional centres with the outlook and status of university units. These centres should be equipped for highly specialized forms of treatment and investigation. Fever hospitals and general children's hospitals should be fused into paediatric units; the present division was artificial and served no good purpose. Long-term patients should be treated in general children's hospitals staffed and equipped to deal with all types of cases. Some children needed treatment in orthopaedic wards, others might lie in cottage homes under the care of house mothers.

Psychiatric treatment should be undertaken by paediatricians and general practitioners, but there should be fully staffed child psychiatric units adjacent to children's hospitals. Many children with psychiatric symptoms needed a full physical investigation. Psychiatrists working in these units should have had practical training in general paediatrics.

Initial Steps

Much could be done to obtain such a service in the immediate future. The first step was the overall planning, at least in outline, and the provision of facilities for training was a primary obligation. Adequate undergraduate training units should be set up, and this would necessitate the provision of much larger departments than existed at present. Properly staffed and equipped regional beds would also be needed for postgraduate training. Appointments should not be filled unless the candidates were of the right calibre and adequate facilities were available. If each hospital sought to create its own department and train its own staff regardless of the larger needs the future of the service might be in jeopardy.

The nursing must be done by nurses who were fond of children, wanted to look after them, and were trained for the work. School nurses and health visitors should also be given the opportunity of keeping up their knowledge of sick children. The interchange of nurses working at clinics or in hospitals should be encouraged. She thought also that mothers should be brought into hospitals to help with the nursing of their own children. "Play" people should be appointed who could provide the children with amusement and occupation. A central bureau should be set up in each region where statistics of child health would be available.

Hitherto there had been little inducement to nurses, medical students, or doctors to undertake paediatric work. If the National Health Service offered in paediatrics the same prospects as it offered in other branches of medicine, said Dr. Mackay in conclusion, the work, which in itself was so rewarding, would gain all the recruits needed.

The National Association for the Prevention of Tuberculosis discusses in a memorandum recently issued the policy for mass radiography in the future. Groups that should receive priority in being radiographed include nurses, doctors, and workers in certain dusty occupations, and entrants to the military and civil services. Other groups might include secondary-school leavers, food handlers, and expectant mothers. The memorandum admits that the work of mass radiography is often monotonous for those who do it and suggests that it should not be regarded as a career in itself but as part of the experience necessary for a fully qualified physician of a chest clinic. More propaganda is favoured to encourage the public to be radiographed, since there is evidence that the initial enthusiasm is waning.

Nova et Vetera

GENERAL ANATOMY, MICROSCOPIC ANATOMY, OR HISTOLOGY?

In Great Britain textbooks of histology have been designed almost entirely for medical students. They have been unsubstantial, as they usually figure tissues and organs from domestic and laboratory animals rather than from man. On the other hand, in Germany at the end of last century, and still more so in the U.S.A. of recent years, comparative histology has attracted the attention of many zoologists. This has largely been responsible for the fact that experimental embryology blossomed in Germany and is now bearing fruit in North America.

Undoubtedly that great French genius Bichat (1771-1802) founded the subject of general anatomy or histology by concentrating on tissues rather than organs, with a hand lens rather than a microscope. The cell theory of the structure of tissues, both animal and vegetable, was founded by Schwann and Schleiden in 1838. Histology bore the name "general anatomy" for some years. Fr. Gerber, of Berne, wrote his textbook of general anatomy in 1840. This was translated by George Gulliver in 1841 with considerable additions. Gerber is worth remembering if only for the statement, "Anatomy and physiology, however, ought never to be regarded as separate sciences, altogether disjoined and different; they are indeed, so closely linked together, that they are all but one and the same; in anatomy, we study the organs in *repose*, in physiology, we study them in *action*." As an example of early teamwork Dr. Gulliver registers his thanks for the engravings to "Mr. Siddall, a zealous micrographer and the worthy veterinary surgeon to the Blues," and to "Dr. Boyd, the excellent resident physician of the St. Marylebone Infirmary, for his friendly assistance on various occasions."

In 1837 William Sharpey was appointed to the chair of anatomy and physiology at University College, London, at the time when Richard Quain (1800-87) held the chair of practical anatomy and served as surgeon to the hospital. Sharpey, with tremendous energy, established a course in microscopic anatomy. The large round table was fitted with a lamp at the centre and a brass rail near the edge, along which the microscope circulated from one student to the other. Sharpey instituted a lectureship in practical physiology "with a view to supplying medical students with instructions in the use of the microscope in examining the texture and fluids of the body." Sharpey, having become professor of physiology, took over the teaching of histology and neurology, so that the department of anatomy was left with no equipment beyond the cadaver, and sank to be the handmaid of surgery.

William Sharpey and Richard Quain published the fifth edition of Jones Quain's *Anatomy* in 1848 with the assistance of Potter, Viner Ellis, and John Marshall. This edition had a new section on general anatomy and also one on surgical anatomy.

The first distinct work in English on general anatomy was that of Dr. Craigie, of Edinburgh (1828). The second was that of Mr. R. D. Grainger, of St. Thomas's Hospital (1829), followed almost immediately by Robert Knox's translation of the textbook of Béclard (1785-1825), which passed through successive editions to 1895. Knox also wrote anonymously one of the earliest books on prostitution, "the greatest of social evils," translated Cloquet's *Descriptive Anatomy*, and wrote on *The Races of Man*. It is sad that this great anatomist is remembered scandalously only as a resurrectionist.

That strange man A. H. Hassall, who not only described the corpuscles of the thymus but wrote the *History of the British Freshwater Algae*, published his two volumes (text and atlas) on the *Microscopic Anatomy of the Human Body* in 1846-9. From the point of accuracy of delineation the lectures on histology delivered by John Quekett at the Royal College of Surgeons in 1851-2, and published in two volumes in 1852, show an improvement on Hassall's work and covered both vertebrate and invertebrate forms, so that the study was comparative in the broad sense. This was followed by the masterly works of Kölliker, who published his compendium.

Mikroskopische Anatomie, in 1850-4 and his shorter *Handbuch der Gewebelehre des Menschen* in 1852. The latter was translated by George Busk and Thomas Huxley and published for the Sydenham Society in 1853. Another translation, by Dr. George Buchanan, of Glasgow, was published in 1860.

There is some doubt when the term histology came to replace the older terms general anatomy and microscopic anatomy. H. D. Rolleston, in his history of the Cambridge Medical School, attributes the origin of the word histology to Michael Foster (1836-1907), who deserted the chair of practical physiology at University College, London, to become Prae-electro of Physiology at Trinity College, Cambridge, in 1870. Rolleston says: "In addition to creating the Cambridge School of Physiology and making physiology an aspect of biology, instead of the younger sister of anatomy, he set the example of practical classes in physiology; the work in these classes included histology, a word introduced by Foster in consultation with F. B. Westcott (1825-1901), Regius Professor of Divinity"—and later the most liberal Bishop of Durham. This statement is obviously wrong, since as early as 1853 Theodor von Hensling published a paper entitled "Histologische Mittheilungen" in Vol. 5 of *Zeitschrift für Wissenschaftliche Zoologie*, and in 1859 Arthur Farre, professor in medical obstetrics at King's College, refers to "histological changes" in the uterus after labour (Todd and Bowman's *Cyclopaedia, Supplement*, 1859). Whereas Hassall spoke of microscopic anatomy in 1849, Quekett spoke of histology in 1851, as did W. B. Carpenter in his book *The Microscope* in 1856. Who really established the usage of the term histology?

The word histology, as distinct from general anatomy or microscopic anatomy, seems to have been introduced by A. F. J. K. Mayer in his book, *Ueber Histologie und eine neue Eintheilung der Gewebe des Menschlichen Körpers bei Gelegenheit der Eröffnung seiner Vorlesungen über Anatomie*, an octavo volume of 40 pages published in Bonn by A. Marcus in 1819. This book is not in the University Library at Cambridge or in the British Museum. It is to be hoped that a copy may be unearthed somewhere amidst that dust which is the bloom of age.

The greatest of all textbooks is still the *Manual of Human and Comparative Histology*, edited by S. Stricker (1869) and published post-haste in an English translation by Henry Power, ophthalmic surgeon to St. George's Hospital, in 1870. The three volumes may still be bought for a song, like so many other historic publications of the New Sydenham Society. The contributors to Stricker's *Manual* included such men as J. Arnold, S. Brücke, Cohnheim, Eberth, Engelmann, Gerlach, Klein, W. Kühne, Ludwig, Meynert, W. Müller, Obersteiner, Pflüger, Preyer, Recklinghausen, Rudinger, Max Schultze, Schwalbe, Schweiger-Seidel, Toldt, Waldeyer, and others. The book is a joy because of the conflicting views of the contributors, the different methods of approach to the subject, and the rich historical background. As Stricker said, "Controversy is the mother of inquiry."

The most exhaustive textbook of comparative histology at present is the *Lehrbuch der vergleichenden Anatomie der Wirbeltiere*, by Albert Oettel and his contributors. Eight volumes appeared over the years 1896-1914.

The third edition of Professor Kendall's book, the *Microscopic Anatomy of Vertebrates*,* which provoked this brief historical review of general anatomy and histology, is a sound attempt to present the students of zoology with an interest in the wider fields of the lowlier vertebrates as well as mammals. His chapter on the integument deals with the skin of dogfish, bony fish, frog, reptiles, and birds as well as mammals. The excretory system of pronephros, mesonephros, and metanephros is pictured in the hagfish, the frog, and the mammal. In the skeletal system the terminology is not clear, as such terms as "precartilaginous,"

**Microscopic Anatomy of Vertebrates*. By James I. Kendall, Ph.D., D.Sc. Third edition, thoroughly revised. (Pp. 354; 225 illustrations £1 10s.) London: Henry Kimpton.

"chondroid tissue," and "pseudo-cartilage" are used. The weakest part of the book is the section dealing with the female reproductive system, a field in which most of our knowledge is due to American workers such as Edgar Allen, Leo Loeb, Stockard, H. M. Evans, and the various contributors to the *Carnegie Contributions to Embryology*. It is confusing to talk of the tunica albuginea of the ovary rather than of the tunica propria, for the former term really belongs to the inelastic coat of the testis. As Astley Cooper pointed out so long ago, this inelastic tunic of the testis has much in common with the dura mater, in that haemorrhage into either testis or brain inevitably leads to destruction of tissue. The placenta, that organ which, like the ideal University of Comenius, supplies sap, vitality, and strength to all, deserves a little more space if only because of its importance in classification of the mammals. The decidua cells are said to develop after the onset of pregnancy, whereas they really develop in every premenstrual phase as well and are heavily stored with pabulum for the nourishment of a fertilized ovum which may never arrive. Nature does not ration essential amino-acids, fats, lipoids, or glycogen. She lays a feast, and is prepared to discard it *in toto* in the menstruum.

It is a useful book for any zoology department, and would be better for the inclusion of a brief historical introduction so that the student might appreciate the part played by the original founders of the subject. The book is on the whole well illustrated, but a few of the diagrams are not up to the level of the photomicrographs. The high-water mark of histological diagrams is found in the woodcuts of Todd and Bowman's *Cyclopaedia of Anatomy and Physiology* (1835-59) and their *Physiological Anatomy and Physiology of Man* (1845).

H. A. HARRIS.

Preparations and Appliances

A SWITCH AND WIRING CIRCUIT FOR UNIPOLAR LEAD ELECTROCARDIOGRAPHY

Mr. A. G. BARRITT, electrocardiographic technician, Royal Infirmary, Sheffield, writes: The use of unipolar lead electrocardiography in the diagnosis of cardiac disorders is rapidly becoming recognized as a standard procedure. Its adoption in this country has been hindered by the difficulty in obtaining suitable apparatus. It is laborious and time-consuming when carried out on a standard electrocardiograph. Records are simple to obtain with the Sanborn Viso-Cardiette, but it is doubtful if the instrument is robust enough for heavy routine work. It was felt, therefore, that it would be advantageous to convert a full-size standard type of Cambridge electrocardiograph so that unipolar leads could be taken rapidly and easily.

An electrical circuit has been constructed in which the substitution of a rotating lead-change switch for the existing one in the Cambridge electrocardiograph has made it possible for standard, unipolar extremity, bipolar, and unipolar precordial

leads to be taken with ease. There is thus no need to interchange the leads, the only adjustment necessary being the alteration of position of the chest electrode.

The circuit has been devised by utilizing a 4-pole, 11-way radio switch, which is cheap and easily obtainable. The accompanying schematic diagram outlines the method of wiring.

A four-lead cable runs from the patient's couch to the electrocardiograph, and the R.A., L.A., L.L., and chest leads are attached in this order to the common terminals of each pole. Starting at position I, a pair of wires leading from the galvanometer circuit is connected round the switch as illustrated. A single-pole short-circuiting switch is incorporated in the circuit to allow the electrocardiograph to be tested without a patient in the circuit. Provision is made for the inclusion, if required, of three 5,000-ohm resistances in the unipolar lead circuits, so that Wilson or Goldberger augmented leads may be taken as desired. No provision has been made for taking lead C.L., as various authorities have stated it to be unreliable.

An additional stop has been placed in the film-lowering mechanism on the camera so that only half the film is exposed on each occasion, giving a shorter record of each lead. Instead, therefore, of having only three leads on a film, it is possible to record up to six leads. It has often been convenient to record leads I-III with precordial leads on one film. Alternatively, when unipolar leads are being taken leads I-III, aVR, aVL, and aVF are recorded on one film and leads V₁₋₆ on a second film.

Some types of valve-amplifier electrocardiograph, such as the Sanborn Cardiette, are fitted with an interference suppressor that is automatically switched to the lead which is out of the patient's circuit. This may be provided for by connecting the L.L. lead from the machine to the L.A. lead and then connecting this junction to the terminal I (L.A.) above. The electrocardiograph is then used with its switch in the lead I position, and all alterations are made on the rotating switch.

The apparatus has proved very suitable for routine electrocardiography, and the saving in time and effort expended on each examination has been considerable.

This adaptation was carried out in the electrocardiography Department of the Sheffield Royal Infirmary under the direction of Professor E. J. Wayne. I am indebted to him and Dr. A. G. Macgregor for their help and encouragement.

[Since writing this description I learn that a device incorporating a similar switch for use in unipolar lead electrocardiography was demonstrated at the autumn meeting of the British Cardiac Society by Dr. V. Edmunds, of the cardiac department of the Charing Cross Hospital.]

Under new regulations the maternity grant of £4 can now be claimed at any time within eleven weeks before (instead of seven weeks before) the expected week of confinement and three months after the confinement. The attendance allowance of £1 a week for four weeks after confinement can now be claimed at any time between the eleventh week before the expected date of confinement and the fourth week afterwards. Previously the allowance could be claimed only within ten days after the birth. If the allowance is claimed in advance it must be accompanied by a certificate of expected confinement, and the same claim form will do for the attendance allowance and maternity grant. The attendance allowance, unlike the maternity grant, cannot be paid in advance or until a certificate of confinement is received. The time limit for putting in this certificate is 28 days after confinement. The maternity allowance—a special benefit in place of attendance allowance for mothers who usually work for employers or in their own business—can now be claimed between the eleventh and sixth weeks before the expected confinement instead of only between the seventh and sixth weeks. This allowance of 36s. a week begins six weeks before confinement and continues for thirteen weeks provided the mother gives up work for this period. If the claim is late and good cause cannot be shown for the delay the allowance may be reduced or withheld. The certificate of expected confinement should be completed by the doctor or midwife; as the examination on which this is based can now be carried out at any time between the eleventh and sixth weeks before confinement instead of only during the seventh week before, the certificate can be obtained after a routine antenatal examination and should not require a special visit. The time for notifying the date of confinement on the certificate enclosed in the order book has now been extended from 21 days to 28 days after confinement. The regulations have been made provisionally, pending the report on them by the National Insurance Advisory Committee. The committee will consider objections to them sent before May 10 to the Secretary, National Insurance Advisory Committee, 6, Curzon Street, London, W.1.

IMPERIAL CANCER RESEARCH FUND ANNUAL REPORT

The annual general meeting of the Governors of the Imperial Cancer Research Fund was held on April 20, when the Earl of Halifax was re-elected President of the Fund. Dr. W. E. Gye, who is retiring on Aug. 11, will be succeeded as general superintendent of investigations and director of the central laboratory by Dr. James Craigie.

Much of the forty-sixth annual report of the Fund is devoted to the work which was undertaken by the present director, his successor, and Dr. A. M. Begg and Miss Ida Mann on the propagation of mouse tumours by means of dried tissue. This work was the subject of an article by Dr. W. E. Gye which appeared in our opening pages in the *Journal* of March 26 (p. 511).

The report mentions the continuing investigation of mammary tumours in hybrid mice by Dr. L. Foulds; studies of the carcinogenic action of azo-compounds by Mr. H. G. Crabtree; and work by Mr. P. C. Williams on endocrinology. Dr. C. C. Spicer has completed an investigation into the incidence of lung cancer in some London teaching hospitals. The last investigation of this kind made in England by Passey and Holmes and by Bonser showed that the great increase in lung cancer recorded by the Registrar-General was not paralleled by the incidence of the disease in teaching hospitals, where the possibilities of errors in diagnosis are presumed to be reduced. Over the 20 years that have elapsed since Passey and Holmes published their findings the increase in the incidence of lung cancer recorded by the Registrar-General has continued. Dr. Spicer's investigation, which is now being prepared for publication, suggests that there has also been an increase in the incidence of lung cancer in London teaching hospitals.

CLASSIFICATION OF DISEASE SIXTH REVISION OF THE INTERNATIONAL LIST

The first of the two volumes of the new *Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death* was published this week. The work of preparing this new list was fully described a few months ago in a leading article in the *Journal* (Sept. 4, 1948, p. 480). The first International List of Causes of Death was compiled towards the end of the last century and was revised at ten-yearly intervals. The present manual represents not merely the sixth revision of the old International List: it now provides a single list which is applicable to morbidity as well as to mortality statistics. This new classification, together with international regulations about its use, was adopted at the First Assembly of the World Health Organization in August, 1948.

The manual contains an introductory historical review and a description of the methods by which the classification has been worked out. The purpose of a statistical classification is to provide a list of disabilities for compiling statistics and not a nomenclature of diseases and injuries. In the words of the introduction:

"Not every condition receives a particular number, but there is a category to which every condition can be referred, and this has been achieved by the method of selective grouping. For instance, a broad group of conditions such as the psychoses is given a two-figure number and is then divided into nine categories corresponding to fairly well defined types of psychoses, and lastly there is a tenth or residual category to which the psychoses which are not already characterized or are ill-defined can be allocated. The principles of determining what conditions should be specified as definite categories are based on frequency, importance, and clarity of characterization of the condition."

The detailed list consists of 612 categories of diseases and morbid conditions, plus 153 categories for classification of the external cause of injury and 189 categories for characterization of injuries according to the nature of the lesion. A decimal system of numbering has been adopted in which the detailed categories of the classification are designated by three-digit

1 H.M.S.O., 1949, London. Published by arrangement with the World Health Organization, Geneva. Price for the two volumes, 30s. net.

numbers. In many instances the first two digits designate important broad groupings. The third digit divides each group into categories which represent specific disease entities or a classification of the disease according to some characteristic, such as anatomical site. This first volume also contains (1) a tabular list of diagnostic terms included within each category (many of the three-digit categories are here subdivided into four-digit categories); (2) three special lists for tabulation of morbidity and mortality data; (3) a section on medical certification and rules for classification provided to assist the compiler of medical statistics; (4) a suggested form of multiple-cause tabulation; and (5) the text of the regulations adopted by the World Health Organization which will govern the use of the classification and the presentation of official statistics from Jan. 1, 1950. The second volume, which is now in the press, will be an alphabetical index of terms and the code number assigned to them.

In the preface to the manual it is stated that the World Health Organization is offering it in the expectation that "it will be not merely an object of interest to medical statisticians, but the instrument for collecting information into a common pool of knowledge from which in time all mankind will benefit." The Registrar-General has expressed the hope that on its publication in this country it will have the widest use among the medical profession, hospital officers, and all others interested in medical statistics.

Reports of Societies

RESECTABLE CARCINOMA OF THE STOMACH

In the Section of Surgery of the Royal Society of Medicine on April 6 a discussion was held on "Resectable Carcinoma of the Stomach."

Professor JOHN MORLEY mentioned, in opening, that he had thought it right to hand over cases of carcinoma of the cardiac end of the stomach to those of his colleagues who were accustomed to the transthoracic approach. Whether the transthoracic approach to carcinoma of the upper half of the stomach, which had so greatly extended the scope of surgery in this field, was left to the thoracic surgeon or whether the abdominal surgeon should accustom himself to this route was a matter for serious discussion. The ideal solution, that the two specialists should work together, was hardly feasible in most hospitals, because the harvest was so great and the labourers so few. But it might be agreed that all surgeons who undertook transpleural gastrectomy must be well versed not only in the technique of gastro-intestinal suture but also in the after-care of patients suffering from a thoracotomy wound.

There was in the profession a widespread feeling of pessimism about the end-results of gastrectomy for cancer. This was not altogether justified, and it did tend to hamper their efforts by leading to undesirable delay before the patient was brought to operation. Doctors who believed that all patients suffering from cancer of the stomach were bound to die within two or three years were not likely to send the patient to the surgeon as a matter of urgency.

As for the proportion of cases in which the cancer could be resected, out of Harnett's (British Empire Cancer Campaign) cases from London hospitals resection was undertaken in only 17.3%, but Harnett himself considered that 26% might be considered as the average rate at present. That accorded with Professor Morley's own experience over the last thirty years. Figures from the Mayo Clinic for cases operated on in 1947 showed that of 275 patients 148, or 53.8%, had growths that were resected; these figures were not comparable with Harnett's or his own because they referred only to the cases operated on and not to all cases diagnosed.

Mortality and Results

The operative mortality in his own list of 140 cases of gastrectomy for cancer was 21.4%. This was far too high, judged by present standards, but these cases included a large proportion operated on in the dark ages of gastric surgery, before much account was taken of such things as the state of

the patient's blood, the serum-protein, etc., and before the "sulpha" drugs and penicillin had robbed chest complications of their terrors. He had always felt that where there was a remote chance of radical cure the patient should be given the benefit of surgery without too tender a regard for one's own statistics. In a series of cases at the Manchester Royal Infirmary from 1940 to 1948 the mortality from gastrectomy was 19.7%. It was worth noting that the mortality rate for the palliative operations was very much the same as for the radical operation—a clear enough indication of the poor material these patients presented. Of those of his patients who survived operation, just over one-half died within three years. Once the patient had got through the first three years the chance of permanent cure was not inconsiderable.

Of the 110 survivors of the operation among his 140 cases, 64 died within three years, but one died after twenty-one and a half years without any recurrence, and the cause of death was coronary thrombosis. Two were alive and well after twenty-one years, two after twenty years, and one after eleven years. Of the late recurrences one was eight years after operation; three were four years after operation. With cancer of the stomach there was not the same remarkable tendency to late recurrence as in cancer of the breast, where local recurrences were not at all uncommon after ten, fifteen, twenty, or even twenty-five years. The main problem in these cases of cancer of the stomach, Professor Morley continued, was to refer them to the surgeon early, though it must be admitted that in the early stages clinical diagnosis amounted to nothing more than a shrewd guess, and they were entirely dependent on radiological findings, fortified on occasion by gastroscopic studies.

Hypertrophic stenosis of the pyloric canal in adults Professor Morley mentioned as closely simulating early cancer of the stomach. Some of these pyloric stenoses were associated with ulcer, some with no other lesion, and in these cases it was difficult to account for its aetiology. The condition might disappear spontaneously. In one of his cases diagnosed radiologically in 1934 in a woman who had complained of indigestion for fifteen years previously there was the typical radiological appearance of hypertrophic pyloric stenosis. He operated on her nine years afterwards and found a chronic ulcer on the lesser curvature, but by that time there was no sign whatever of the hypertrophic pyloric stenosis.

The type of gastrectomy for cancer which he had found most satisfactory was a modification of the Billroth I operation usually associated with the name of Schoemaker, who devised it. He thought that after this operation there was less tendency for post-gastrectomy anaemia to appear. For cancers of the cardiac end of the stomach, transthoracic gastrectomy was the method of choice. Many of these operations would be total gastrectomies, but in his view the real hope of controlling this condition lay not in ever more extensive operations but in diagnosing the condition so early that as far as the more favourable pyloric growths were concerned a subtotal gastrectomy would be effective. Some surgeons had suggested that total gastrectomy ought nowadays to be preferred to subtotal gastrectomy even for neoplasms in the pyloric half of the stomach. He thought that was wrong. Total gastrectomy would mean a greatly increased operative mortality, without much prospect, if any, of a compensating increase in the number of permanent cures. Ultimately, in the back of their minds at any rate, they might cherish the hope that the biochemists would find a remedy which would make the surgeon's efforts in this field no longer necessary.

Truly Radical Resection

Mr. N. C. TANNER agreed with Professor Morley that a pessimistic attitude was wrong. Radical resection of the tumour, even if death took place within five years, as it did in the majority of cases, relieved pain, vomiting, and anaemia, and restored the patient to his home and usually to his work. In view of the age at which gastric carcinoma usually appeared, a year or two of this relief represented a valuable addition to the patient's life. Diagnosis was little or no better than it was ten years ago, but the operative mortality had diminished for operations on all parts of the stomach, so that with the much higher number of resections and the higher proportion of survivals an increase in the number of patients surviving for five years or more could be predicted.

R Fersolate for iron therapy

in any case

Whatever the cause of iron deficiency anaemia, Fersolate provides the certain, simple answer. Fersolate was the first tablet to combine iron, copper and manganese, and this same formula has been adopted in the National Formulary. Indeed, Fersolate has held a unique reputation with the medical profession for sixteen years. Following a new government regulation, Fersolate is again available in dispensing sizes under the brand name, and can be supplied against your prescriptions without being subject to purchase tax. Once again, therefore, you can specify Fersolate *by name* on all iron prescriptions ensuring that your patients receive the original, well-proven preparation.

In tins of 1,000 & 5,000
for dispensing purposes

GLAXO LABORATORIES LTD.,
GREENFORD, MIDDLESEX. BYRON 3434

★ The dispensing size of the vitamin-mineral tonic, Syrup Minadex, is also now freed from purchase tax, together with all sizes of Ethamolin—the sclerosing treatment for varicose veins.

Nearly home . . .

but it seems like miles

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of 'feeling generally run down'. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B, 0.5 mg., riboflavine 0.75 mg., nicotinamide 7.5 mg., in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

'Vibelan'

LONDON HOSPITAL CATGUT

*(Morley's Process)***AND****TENSILE STRENGTH**

THE self-imposed arbitrary standard set for London Hospital Catgut at its inception is above that of the B.P. Codex and the U.S.A. Pharmacopoeia. The London Hospital standard has never been departed from and is still maintained.

This outstanding feature, together with an

elasticity (elongation) approximating 40%, affords the Surgeon perfect safety in using fine sizes compatible with modern technique.

When using London Hospital Catgut we strongly recommend Surgeons to use B.P.C. sizes 2/0, 0, and 1 for general surgery and B.P.C. sizes 3/0 and 4/0 for very fine work.

THE LONDON HOSPITAL (LIGATURE DEPARTMENT), LTD., LONDON, E.1, ENGLAND

Although total gastrectomy by the abdominal route had been successfully carried out for many years, there was no doubt that, except in a few cases with lax viscera, it was technically difficult, and the end-result was often an insecure anastomosis. For truly radical resection it might be desirable to remove some part of the lower oesophagus, which was often difficult or even impossible by the abdominal route. The more liberal oesophageal resection had almost eliminated that unfortunate group of cases in which recurrence took place on the suture line. Of late years there had been a great widening of the limits of resection; upward and downward extensions to the oesophagus and the duodenum had taken place, but after these massive resections the patients as a rule remained in good condition.

Professor F. A. R. STAMMERS said that the chief hope lay in early diagnosis in these cases of gastric cancer. When a person of 50 developed some dyspepsia unexplained by x rays or gastroscopy laparotomy should be undertaken to make certain that the opportunity of eradicating a growth was not being missed. Most patients died of secondaries in the liver or wider metastasis, but a few died of recurrence in the stomach itself. In a small group of cases in Birmingham, in 12 subtotal gastrectomies there had been one post-operative death, and in 7 total gastrectomies two operative deaths. The decision as between total and subtotal gastrectomy was best left to the surgeon at the time of exploration. Of post-operative features he mentioned regurgitation, especially when the operation went a little above the diaphragm. This often led to glossitis, which, however, responded to the exhibition of vitamin B. This regurgitation was most marked after total gastrectomy. Another post-operative effect was a feeling of fullness after meals.

Mr. R. C. B. LEDLIE showed a film illustrating the operation which he carried out at the Royal Cancer Hospital, and summarized a series of cases which had been under his care. Unfortunately, owing to a technical hitch, Mr. Ledlie's interesting film was not well shown.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM ANNUAL CONGRESS

The annual congress of the Ophthalmological Society of the United Kingdom was held at the Royal Society of Medicine from March 31 to April 2. Mr. FRANK A. JULER, who presided, welcomed the visitors from other countries, and announced that a medal would be presented to future Bowman lecturers and that meanwhile one of these tokens was now available for each of the former lecturers. Sir JOHN PARSONS, FRS, who was the Bowman lecturer in 1924, thereupon received his medal from the president. So also did Professor H. J. M. WEVE (1939) and Professor MARC AMSLER, last year's Bowman lecturer. Arrangements were made to send medals to the other surviving lecturers: Sir ARTHUR KEITH (1930), Professor VAN DEN HOEVE (1932), and Dr. ARNOLD KNAPP (1946).

Scientific Papers

The presidential address embraced two subjects of wide clinical significance: "Some Points in the Operation for Acute Glaucoma" and "Some Reflections on Refraction." Mr. Juler emphasized the enduring value of von Graefe's work on glaucoma and stressed the dangers which might arise from operative wounding of the corneal endothelium. He put in a plea for prompt surgical treatment in cases not responding to miotics and other medical remedies. On the subject of refraction, certain fallacies in connexion with retinoscopy were mentioned, and the need for accuracy, especially in working with children, was discussed. The president also reviewed the special problems of presbyopia and anisometropia. In considering oblique astigmatism he dwelt on the possibility of exploiting the work of Bielschowsky and others on ocular torsion consequent upon tilting of the head towards either shoulder.

A lucid and well-illustrated survey of the technique of plastic operations in the neighbourhood of the orbit was contributed by Mr. D. N. MATTHEWS. He demonstrated some of his results in cases of congenital ptosis treated by a modification of Błaskowicz's operation, and described his method of treating epicanthus. Other subjects touched on were the reconstruction

of damaged eyelids and tear-ducts and the plastic repair of a socket.

Dr. S. P. MEADOWS described the symptoms and signs arising from internal carotid artery aneurysms. Two other neuro-ophthalmological contributions were read by Dr. MACDONALD CRITCHLEY. In discussing the problem of awareness or non-awareness of visual field defects he emphasized the importance of associated disturbances in cerebral function whereby large gaps in the visual field might be masked. In ordinary clinical practice patients complaining of metamorphopsia were usually found to be suffering from macular lesions, but Dr. Critchley's second paper served as a reminder that changes in the apparent shape of objects could be caused by intracranial disorder. Toxic, traumatic, vascular, and neoplastic disturbances of the occipital cortex could all produce metamorphopsia, to say nothing of elaborate hallucinations.

Dr. E. HARTMANN, of the Hôpital Lariboisière, Paris, spoke on the clinical estimation of pressure in the retinal arteries. He admitted that Baillart's ophthalmodynamometer was not entirely accurate, but pointed out that few clinical methods were foolproof. If the observer learnt the technique of application and realized its limitations, then Baillart's instrument would serve as a guide to the comparative pressure in the retinal arteries of different subjects or of the same subject at different times.

The reduction of intra-ocular tension by curare, retrobulbar procaine, and di-isopropyl fluorophosphate was the subject of a review by Mr. J. R. WHEELER. Mr. EUGENE WOLFF showed some excellent histological pictures to illustrate his notes on normal and pathological ocular pigment. Mr. W. J. WELLWOOD FERGUSON and Dr. ALASTAIR G. MACGREGOR spoke about congenital total colour-blindness, with otosclerosis and hypertension as associated hereditary abnormalities. They described four cases and discussed the genetical significance of this syndrome.

Dr. A. C. COPPER (Leiden) read a paper on the measurement of the retrobulbar resistance. He discussed the concept of orbital tension, explained how the results of orbitonometry could be set out in graphic form, and stressed the value of the orbitonometer in distinguishing between inflammatory and neoplastic proptosis.

Dr. G. KARPA (Stockholm) described his work on clinical electroretinography, and indicated its practical importance in diagnosis and prognosis. Some problems in ophthalmic dispensing were discussed by Mr. J. PIKE from the standpoint of a dispensing optician. Dr. J. BERKSOV read a paper dealing with the clinical significance of retinal arteriolar spasm in the toxæmias of pregnancy.

Corneal Grafting

Intensive work on corneal grafting has been facilitated in many countries by permission to obtain donor material from the fresh cadaver. Those who attended the discussion on this subject were fortunate in being able to hear the experiences of so many recognized authorities. Professor A. FRANCESCHETTI (Geneva) gave a brief historical review of corneal grafting, and pointed out that equally good results might be obtained from techniques exhibiting many differences in detail, so long as the operator worked with discrimination. They were now in a position to give a more accurate prognosis than had been possible formerly. It was generally realized now that aphakic cases and those with traumatic leucoma were not good subjects for grafting. Some of the best results, on the other hand, had been obtained in cases of corneal dystrophy, although Fuchs's endothelial dystrophy was in this respect an unfavourable exception.

Details of operative technique were discussed by Mr. J. W. TUDOR THOMAS, who said that in his experience the chances of a successful graft were enhanced by the presence of opaque cornea at the site of implantation. He also pointed out the danger of trying at the time of operation to remove the membrane which is so frequently found beneath the cornea in cases of old endocyclitis. Professor G.-P. SOURDILLE (Nantes) discussed the influence of associated ocular and palpebral lesions upon the outcome of corneal grafting, and made special reference to the adverse effect of aphakia and of a large symblepharon. Dr. L. PAUFIQUE (Lyons), who was part author with Professor G.-P. Sourdille and Dr. G. Offret of the 1948 report

of the Société Française d'Ophthalmologie on corneal grafts, showed a film of a peripheral lamellar graft to demonstrate his technique. Such grafts might directly improve the vision in cases of superficial scarring, or prepare the way for a subsequent whole-thickness graft, or exert a therapeutic effect upon certain disorders of the cornea—especially neurotropic lesions.

Other films of operative technique were shown by Dr. J. I. BARRAQUER (Barcelona), Dr. A. FRITZ (Brussels), and Mr. B. W. RYCROFT. Mr. D. P. CHOYCE described the work which he is doing at the Institute of Ophthalmology on superficial lamellar keratoplasty in rabbits. Dr. R. CASTROVIEJO (New York) showed colour photographs of his operative results after whole-thickness grafting. The possibility of encouraging a graft by the administration of vitamins and amino-acids was mentioned by Professor G. B. BIETTI (Pavia), who also gave an account of his technique and operative results.

THE LIPOIDOSES

At a joint meeting of the Liverpool Medical Institution and the Manchester Medical Society on March 2 Professor Sir HENRY COHEN delivered an address on the lipoidoses.

He said that interest in the lipoidoses began nearly a century ago with the description by Addison and Gull of the lesion now labelled xanthoma multiplex. Several diseases were subsequently regarded as lipoidoses, their common feature being the "foamy" cell. Increasing knowledge of lipid metabolism and more intensive histological study had helped towards a clearer understanding of these conditions, which though superficially diverse had been shown to be different facets of a uniform process. Excluding neutral fats, the lipoidoses revealed disturbances in the metabolism of (i) *phosphatides*, of which the monoaminophosphatides, lecithin and cephalin, and the diaminiophosphatide, sphingomyelin, were of major importance; (ii) *cerebrosides*, among which kersin was significant; and (iii) *cholesterol*, which played an important part in sex hormone disturbances and in connexion with bile and vitamin D.

In disease excess of lipid might appear in the intercellular spaces or within the cell. Extracellular lipid deposits were seen in such degenerative changes as lipid proteinosis and necrobiosis lipidica diabetorum. Accumulation of lipid within the cell could arise from hyperlipaemia, the excess lipid being taken up by cells of the reticulo-endothelial system; from abnormal cellular metabolism leading to excessive production of lipid within the cell; or from both factors. It seemed that in disease one of the lipoids was primarily involved and that the others were affected in lesser degree. Thus phosphatide metabolism was disturbed in Niemann-Pick disease and Tay-Sachs's disease; in Gaucher's disease, kersin appeared the predominant cellular lipid.

Xanthomatoses

The xanthomatoses associated with disturbances of cholesterol metabolism fell into three groups. The first appeared to be the direct outcome of a hyperlipaemia, and disappeared when its cause was removed; this group included familial types and those associated with diabetes mellitus, hepatic inadequacy, glycogen storage disease, lipid nephroses of all types, and myxoedema. In this group extensive and diffuse cutaneous xanthomatosis of the neck, back, palms, and soles was often found. The second group comprised xanthoma palpebrarum, xanthoma tuberosum et planum, xanthoma tendinosum, xanthoma of blood vessels and endocardium (often responsible for familial and hereditary forms of coronary occlusion), and xanthomatous biliary cirrhosis. These, though associated with hypercholesterolaemia, showed evidence of intrinsic cellular dysfunction; they were not separate diseases and all the types might be found in the same patient. In these cases there was no significant reversal of the changes on withholding lipoids. In the third group were included xanthoma disseminatum, Hand-Schüller-Christian syndrome, and eosinophilic granuloma of bone; in these the blood cholesterol was normal. The pathological changes had a common pattern; all variations and gradations of change occurred, depending on the sites of the lesions and whether the predominant cell was the primary histiocyte or its acidophil or "foam" cell modification.

Correspondence

An Unfortunate Precedent

SIR,—In the leading article headed "An Unfortunate Precedent" (April 23, p. 717) you suggest that Fellows of the Royal College of Physicians may hesitate in future to criticize the President lest they be passed over when distinction awards are made. This is regarded by us as an unwarranted insult.

If, as is suggested, the presidents of the Colleges are not to sit on the Awards Committee because they might favour their own Fellows, it is a little difficult to see why you raise no objection to the presence on the committee of the President of the British Medical Association, who presumably might be tempted to hold a brief for those specialists connected with his Association. The three surgeons on the Awards Committee, who represent English surgery, are prominent Fellows of their College. Are they too to resign? The logical issue of your argument is that no one who holds office of any kind or is connected with any university or medical school should serve on the committee, because he is liable to a charge of favouritism. It would be convenient, of course, to those who have been hostile to the Awards Committee from the outset if its authority were undermined in this way, for it would hardly command the confidence of the profession and of the public if no one who was anyone was a member.

It was Lord Moran who proposed in the House of Lords that there should be a Spens Committee on the remuneration of specialists, and, as you yourself admit, "he has by his skill in negotiation rendered the profession notable service." Though he would be the first to admit how much he owed to the sympathetic attitude of the Minister of Health, his efforts have been rewarded by terms of service which are considered by most consultants and specialists to be just and even generous. Of these terms the awards are an essential part. It is easy, of course, before the committee has got to work, to excite suspicion that it will not be in possession of the necessary information and that it will not be impartial. But when a responsible medical journal fosters that mistrust we believe it is doing a grave disservice to consultants and specialists.

We are convinced that the Awards Committee will eventually disarm any opposition there may be to what is, after all, a novel idea by its care in sifting evidence and by its desire to be just to every section of specialists.

It is surely unfortunate that, at a time when the presidents of the Colleges have been trying to help to get more favourable terms for general practitioners, particularly in the matter of betterment, there should be attacks of this kind which threaten unity.—We are, etc.,

DONALD HUNTER,
J. CRIGHTON BRAMWELL,
J. FOREST SMITH,
R. V. CHRISTIE,
Censors.

Royal College of Physicians, London, S.W.1.

W. G. BARNARD,
Treasurer.
H. E. A. BOLDERO,
Registrar.
W. D. W. BROOKS,
Assistant Registrar.
ARCHIBALD GILPIN,
Harveian Librarian

SIR,—You are not alone in feeling some disquiet at the appointment of the President of the Royal College of Physicians as chairman of the Committee for Distinction Awards to Specialists. Many young specialists, especially physicians, who incidentally, if they are members of the College, have no voice in the election of their president, must feel that a cloud no bigger than a man's hand has risen on their professional horizon.

That no one questions for an instant the integrity of Lord Moran, that his services to the profession command respect if not always approval, are matters beside the point; the fact is that from now on a young man with an eye to his future will have to think twice before he criticizes, however legitimately, any matter within the province of the President of the Royal College of Physicians, and even the mildest terms of approval, not normally to be reckoned as the "base coin of adulation," must be suspect in the eyes of his own contemporaries and competitors.

There is no reason to believe that Lord Moran wishes to make himself immune not only from the criticism of the

ambitious but also from the praise and openly expressed admiration of the self-respecting. Therefore it is to be hoped that he will reconsider his acceptance of this chairmanship, which may not only undermine the high esteem in which he is held both by his own contemporaries and by many younger specialists but also—and perhaps this is more serious—prove a heavy blow to the integrity and independence of the great College of which he has the honour to be president.

Finally, Sir, under the circumstances I beg to be allowed to sign myself,

YOUNG SPECIALIST.

Second Thoughts on Proguanil

SIR,—Owing to the fact that the *Journals* of Jan. 15 and 29 have only just reached me, having had to be returned to England from my station in Nigeria, the article on proguanil by Sir Gordon Covell, Dr. W. D. Nicol, and Messrs. P. G. Shute and M. Maryon (Jan. 15, p. 88), your leading article (p. 106), and Sir Gordon Covell's letter (Jan. 29, p. 192) have only now come to my notice. I have had considerable clinical experience of the prophylactic use of proguanil, as well as its therapeutic use in the treatment of subtertian malaria, during my last tour of eighteen months on the plateau in Nigeria.

I think that you were perfectly correct in stressing in your leading article the question of lack of appetite, etc., caused by the drug as a matter of moment. In my experience a complaint of lassitude, lack of appetite, and, quite often, looseness of stool is common in Europeans taking a 100-mg. dose of proguanil daily prophylactically. Examination of these cases, including blood and stool examination, revealed nothing except, in rare cases, an occasional *Plasmodium falciparum* parasite. I diagnosed them as "low fever" and prescribed mepacrine, 100 mg. thrice daily for five days or more. The effect of this was spectacular, and about the fourth day the symptoms had cleared up so much that in several cases I was asked if mepacrine was a "tonic." It was interesting that in most cases the symptoms did not appear until the patient had been taking proguanil for at least two or three months, so it is to be presumed that the effect of the drug is cumulative. Or are the symptoms due to malaria breaking through the prophylactic?

In the clinical treatment of malaria I was very much disappointed with the results when using proguanil alone, and finally gave up its use as a sole cure when one patient showed ring forms of the subtertian parasite after 800 mg. of the drug on the three previous days (that is, two tablets four times daily). It was obvious from a clinical point of view that there was a time lag in the disappearance of clinical symptoms. This is a serious defect, especially in cases where cerebral symptoms are present.

The cases in which vomiting is a symptom of acute malaria are very common, and my records show that over 50% of Europeans met with have this symptom. In many cases the vomiting is not severe, and a little sedative premedication allows the oral administration of the antimalarial drug. In probably about 10% of cases the parenteral administration of a remedy becomes necessary, either because of vomiting or because of the need to obtain immediate action of the drug owing to the presence of cerebral symptoms. In these cases quinine or mepacrine has had to be used, as no soluble proguanil was available. I stress this point in order to emphasize that any drug for the treatment of acute subtertian malaria must be available for use either by the intravenous or intramuscular route. In unconscious cerebral cases immediate action by intravenous methods is essential, so up to the present we have been limited to the use of quinine in such cases.

I have seen Dr. John Lowe's letter (April 2, p. 589). I am judging the efficacy of proguanil by its use in controlling and eradicating malaria in Europeans. Nearly all my practice has been among such people since the drug was introduced, but a small supply used in the infant-welfare clinic at Aba early in 1947, during my previous tour, did not impress me with its efficacy. The cases were, however, more allied to the non-immune European, as they had not lived long enough to acquire the immunity that the adult indigenous populations of malarious areas in the Tropics do acquire, so I can say that I have had practically no experience of the treatment of malaria with proguanil in a native population.

I agree with Dr. Lowe that mepacrine is much more toxic than proguanil, but the toxic effects of the latter are not as negligible as he and Sir Gordon Covell suggest. I do not think that your leading article overstated the case, and great care will be required in introducing proguanil on a large scale in the already undernourished populations so often found in malarious areas of the Tropics.—I am, etc.,

Southborough, Kent.

GAVIN SHEARER.

Fish Poisoning

SIR,—In response to the annotation on fish poisoning (Feb. 19, p. 317) I am stimulated to record my experience in another Pacific island—namely, Niue or Savage Island. During the early nineteen-thirties, long before there was any possibility of dumped war materials, I would occasionally see practically a whole native village down with fish poisoning. The toxin was presumably neurotoxic, as paralysis of the legs and extreme bradycardia (pulse rate 30-40) were common symptoms. Poisonous fish fed to cats gave rise to paralysis of the hind legs.

Poisoning occurred through the consumption of a fish known to the natives as "meito." The interesting feature was that, although on the "liku" or windward side of the island this variety is never poisonous, yet on the leeward side of the island the fish is poisonous at certain times of the year which were quite unpredictable. The Niueans, although well aware of the danger, were always ready to take the risk, possibly on account of the shortage of protein in their diet. Taking into consideration the geographical and seasonal distribution, I concluded that the fish became poisonous through eating some poisonous marine growth.—I am, etc.,

Dunedin, New Zealand.

G. O. L. DEMPSTER.

Hospitality for Overseas Visitors

SIR,—The response to my appeal last year (*Journal*, April 24, 1948, p. 809) for hospitality in doctors' homes for our medical visitors from the Dominions and Colonies was most generous and, in fact, more than covered our needs at that time. The Empire Medical Advisory Bureau is now well established, and a report of its work (*vide* Annual Report of Council, 1948-9, *Supplement*, April 2, p. 199) shows that we are in touch with some hundreds of overseas doctors and families with correspondingly great opportunities of getting to know one another.

Most of our overseas medical visitors are in this country for postgraduate education lasting at least a year and often 2-3 years, and while the more fortunate ones may get about and see the country during vacations many do not, and in any case "sight-seeing" is not getting to know one another in our homes. A week-end in the country or by the sea is a most welcome change to men working hard in unaccustomed grimy cities.

May I appeal again, therefore, through your columns to the generously hospitable instincts of our members to help make our visitors welcome in their visits to "the old country." I shall be very glad if doctors willing to offer hospitality to our overseas visitors for one or two days, or even longer, would write to me stating what they are able to offer.—I am, etc.,

HUGH A. SANDIFORD.

Empire Medical Advisory Bureau, B.M.A. House,
Tavistock Square, London, W.C.1.

The Deaf-blind

SIR,—In England and Wales there are more than 4,000 deaf-blind persons on the official register. This number may be a matter of surprise to many. These doubly handicapped people present a problem of peculiar difficulty to the local authorities responsible for their welfare. Obviously they need special attention in addition to financial help. Teaching the manual alphabet is one of the services which local authorities, through their home teachers, provide for the deaf-blind.

Last year an appeal for the deaf-blind on the wireless was made by a deaf-blind man, Mr. Arthur Sculthorpe. His voice was normal and his articulation perfect. His letter in reply to an inquiry about how long he had been deaf was of unusual interest, and some of the points in it seem deserving of wider publicity. He is 44 years of age, had perfect hearing up to

the age of 24, and had been "stone-deaf" since he was 27. He writes :

"I was able to live an ordinary life until I lost my sight also ten years ago. I cannot explain why it is that I retain normal speech, unless it is that I have never ceased to use my voice. Most deaf people are forced, by the shunning of them by ordinary people, to seek their company among other deaf people, where the voice is not used, and so there is a lack of that practice which is absolutely essential when the hearing is not there, to keep the voice in proper condition. I never went into the deaf world, but determined that I would have normality or nothing. I have some idea of control of pitch and volume by the feel of my throat. But although I can speak normally, I find I cannot sing. The range has so contracted that I cannot now reach beyond one octave, nor can I control the pitch of a note to hold it . . . I have noticed since I became deaf that I can 'hear' and 'see' a nerve shock. If I have a sudden nerve shock (as when someone taps me when I thought I was alone) I hear a sound like the banging of a heavy door, and I can see a flash of light. This also occurs when dropping off to sleep. 'Noises' are always there, but normally are so much of the background that one does not worry about them. They increase when one is tired or under some special strain."

There is admittedly considerable room for development in this very difficult field of welfare. The need for and importance of voluntary helpers are recognized. Our profession has its share of responsibility in seeing that these unfortunates are placed on the official register so as to be able to obtain the help provided by the authorities, and also in forming a more informed public opinion in this regard so that the voluntary helpers needed may be forthcoming.

Information about ways of assisting these doubly handicapped sufferers can usually be obtained by getting into touch with the home teacher employed by the local authority or by writing to the National Deaf-Blind Helpers League, 40, Green Road, Hall Green, Birmingham, 28.

—We are, etc.,

HERBERT CAIGER.
L. HADEN GUEST.

Smallpox Contacts

SIR,—I had to deal with four smallpox contacts from the s.s. *Mooltan*. Fortunately—with their consent—I was able to keep them under close observation at our isolation hospital.

This is an age of travel, and it seems to me that if certain countries insisted on the protective inoculation of persons leaving their shores the procedure would be of the highest practical importance in preventing variola major from entering this country. This applies particularly to ships calling at Indian ports. I take it this is a matter for the World Health Organization.—I am, etc.,

Halifax.

G. C. F. ROE,
Medical Officer of Health

Dosage of Heroin

SIR,—Dr. Cranston Walker's memorandum (April 9, p. 619) entitled "Dangerous Symptoms after Injections of Heroin (Diamorphine)" must not be allowed to go unchallenged. It must be pointed out that in Case 1 a dangerous overdose was given. The official dose by injection is 1/24 to 1/8 gr. (3 to 8 mg.), and here in a woman already very ill—"pale and rather limp, pulse rapid and breathing shallow and rapid"—X. Y. Z. gives a dose of 1/2 gr. (22 mg.). Now this is equivalent to nearly 1 gr. (65 mg.) of morphine in effect, and the signs and symptoms that followed could only have been expected. In Case 2 a woman obviously unfit and aged 65 is given a dose greater than the pharmacological one, again with alarming results which might have been foreseen.

Heroin is a very potent and very valuable drug, and it would be a great misfortune for it to be brought into disrepute on account of these two cases. Its chief disadvantage, of course, is the liability to bring about addiction because of its pleasant effects, but if this is borne in mind it is the analgesic of choice in many cases.—I am, etc.,

Hove, Sussex

J. H. CRAWFORD.

SIR,—I was interested to read the memorandum by Dr. Cranston Walker (April 9, p. 619) in which he describes two cases of severe and dangerous respiratory depression produced by heroin. Might I suggest that the cause of the trouble in both cases was overdose?

Most authorities nowadays regard heroin as being about four to five times as powerful as morphine. Cushing,¹ for example, states that "a study of the analgesia resulting from the use of the opium group of alkaloids showed that to produce equal degrees of effects heroin in 1.5-mg. doses was as efficient as 8 mg. of morphine." The maximum official dose of heroin, incidentally, is 1/2 gr. (8 mg.). Is it any wonder, then, that a woman of 40, in a state of exhaustion, should develop alarming symptoms after a dose of 1/2 gr. (22 mg.)?—an equivalent dose of morphine would be 1 1/2 gr. (87 mg.). Dr. Walker mentions that in three or four previous cases X.Y.Z. had injected 1/2 gr. (11 mg.) of heroin with little apparent effect. If this is true, those cases must either have been habituated to the drug or have had an abnormally high metabolic rate. In the second case reported by Dr. Walker a woman aged 65 developed severe respiratory depression after a dose of 1/2 gr. of heroin.

I submit that in both these cases it was the dosage which was at fault and not the drug. An important point to remember is that the dose of any of the opium derivatives per pound of body weight is directly proportional to the metabolic rate. Guedel,² pointing this out, writes :

"The employment of a routine dose of morphine is folly. With a low metabolic rate (hypothyroidism), morphine 1/2 gr. (16 mg.), or even 1/2 gr. (11 mg.), may paralyse respiration in an apparently well-developed adult. With a high metabolic rate, morphine 1/2 gr. will make but little impression. For example, morphine 1/2 gr. (24 mg.) will produce no more effect in a patient with a metabolic rate of 25% above normal than 1/2 gr. will produce in normal, or 1/2 gr. with metabolism 10% below normal."

In this connexion it is worth noting that the metabolic rate of a woman in labour is greatly increased. It is possible, therefore, to give relatively large doses of heroin with safety during labour³ and thus exploit the analgesic properties of the drug to the full.—I am, etc.,

Garlands, Carlisle.

Marriage Neurosis

SIR,—I was very glad to read Dr. R. Macdonald Ladell's condemnation (April 9, p. 635) of the indiscriminate use of E.C.T. and of the equally dreadful operation of leucotomy. It has become apparent to me in practice that there is a great increase in the use of E.C.T. in difficult cases without any previous attempt at psychiatry. Surely the resort to E.C.T. is a confession of failure on the part of the psychiatrist, as it is purely a mechanical operation divorced from all conception of the aims of psychology. I am grateful to Dr. Ladell for calling attention to a practice which must bring discredit to psychiatrists in particular and to the profession in general.—I am, etc.,

Manchester, 12.

J. I. MILNE.

SIR,—It was with considerable pleasure that I read Dr. R. Macdonald Ladell's letter on "marriage neurosis" (April 9, p. 635), and I would like to affirm his contention that E.C.T. in out-patient use is in danger of being used as a short cut to alteration of behaviour which leaves hidden the real distortions of relationship which are the core of a neurosis. His letter is the more timely in that in the psychiatric clinic of the future the temptation to use E.C.T. more and more instead of less and less will be considerable.

E.C.T. is still an empirical treatment. I have been using it as an adjunct to psychotherapy since 1943, and I have come to the conclusion that it has many effects, of which the most noticeable both to psychiatrist and patient is the physical rejuvenating effect, which may be through activation of basal metabolism *per se* or may be an action on the endocrine system via stimulation of the subthalamic structures. In the purely psychic field it seems to have the property of putting a brake on a vicious circle of intolerable anxiety, and it also has a later effect of bringing together the cracking façade of a perfectionistic attitude. It would be a pity if psychiatry took only the narrow view of the first, and perhaps the second, effect, and in this lost sight of the disturbed psychodynamics behind the third, and even the second, effect. If the wider outlook

is not taken and enough psychotherapy, simple and direct as it may have to be, not given to inelastic mentalities, what we are doing is no more a "cure" than is the giving of opium to a case of phthisis the curing of consumption.

There is no denying that for some cases E.C.T. is an indicated therapy, but this should never blind us to the fact that the end of therapy for the neuroses is an improvement of human relationships, even though this may mean the offering at the clinic of a stable relationship once a week for a year or more. Marriage is one of the largest of human relationships, and to attempt to assess and deal with the difficulties of one partner without coming to know something of the other, and without a regard to the relationship between them, is like trying to lift a log by one end only.—I am, etc.,

Erefter.

L. F. DONNAN.

Tuberculous Meningitis

SIR.—I have been reading with interest the excellent article on tuberculous meningitis by Drs. J. Rubie and A. F. Mohun (Feb. 26, p. 338) and the annotation (p. 357) that remarks, "Perhaps the strongest impression made by this paper is the necessity for early diagnosis and the skill which may be required in reaching it." The authors stated that the commonest interval between the first appearance of signs or symptoms and the day of diagnosis was 8-15 days. We should not be satisfied with these results. We are compelled to admit that streptomycin has brought about a revolution in treatment but not in diagnosis. The revolution to be made in diagnosis consists of not waiting till the diagnosis is sure, but sending the child to hospital without delay where there is the slightest suspicion of tuberculous meningitis. It would be too much to suspect a child in out-patients', at the first examination, of having tuberculous meningitis because he has slight fever or is complaining of headache, constipation, diarrhoea, or anorexia. But when the child is under 4 years of age and the Mantoux reaction is positive, the situation is changed; then irritability, listlessness, fatigue, failure to gain (or loss of) weight might be symptoms of tuberculous meningitis.

The means of reaching the earliest diagnosis of tuberculous meningitis is: (1) To perform the Mantoux reaction on all children who come to examination. (2) To send all Mantoux-positive children for regular supervision in the first year of the infection. (3) The mothers must be taught to bring these children for occasional examination whenever they are unwell. In a young tuberculin-positive child all symptoms might belong to tuberculous meningitis unless an alternative diagnosis is clearly demonstrated. So thinking, we should not attribute minor degrees of irritability to teething and feeding difficulties before excluding tuberculous meningitis. Should fits occur, we should perform lumbar puncture without delay. When a child has the symptoms of appendicitis we should not hesitate to perform the operation, but careful investigation whether or not the abdominal signs are those of tuberculous meningitis is necessary. When we see a child with otitis media and meningitis it is not certain that the meningitis is of otic origin: there may be two separate illnesses—otitis media and tuberculous meningitis. I have seen two unnecessary operations.

I stated in 1923 that the low sugar level may be the earliest informative change in the C.S.F. in tuberculous meningitis.¹ The low and falling sugar curve I described was often helpful in the diagnosis of tuberculous meningitis. I learned for the first time in 1925 that convulsions can increase the sugar level in the C.S.F.² For this reason I do not accept a normal or high level of sugar in the C.S.F. as a sign excluding the diagnosis when convulsions have appeared before lumbar puncture was made, but we repeat it two days later. It was pointed out in investigations by Beck and myself in 1924 that the chloride content of the C.S.F. is often insignificantly lowered at the early stage, and a falling chloride content occurs in meningism also.³

It is important to separate tuberculoma of the meninges and brain from tuberculous meningitis. In the former illness the protein level and the number of the cells could be elevated, but the sugar level in the C.S.F. is normal. In tuberculous meningitis the protein is raised, the cell count increased, and the sugar is low. Acid-fast bacilli can be detected in the C.S.F. in both illnesses. When the prodromal stage lasts as long as three months and the child recovers completely we should consider this the first seeding of a tuberculoma in the meninges

or in the brain. The long duration argues against the tuberculo-toxic meningeal irritation. In my cases, when the first lumbar puncture was normal and the C.S.F. became abnormal five to fifteen days later (after the onset of the symptoms), it appeared that the first symptoms originated from the small caseous cortical tubercles and caseous meningeal plaques. Meningitis developed when these foci broke down, with the dissemination of organisms.—I am, etc.,

Budapest.

Whither Tuberculosis?

SIR.—While agreeing with Dr. S. G. Tippet (April 9, p. 634) in his desire to eradicate tuberculosis and his implied desire to see the end of sanatoria, several points in his letter provoke comment. If it is expected to discover every case of tuberculous infection in its infancy or before it has a chance to manifest itself in tuberculous disease—though the overwhelming majority of such infections never do so anyway—tuberculin testing would have to be reapplied every few months to the entire tuberculin-negative population, for in young people the development of tuberculous disease can be a pretty rapid process.

Would the information gained have any value in preventing the onset of the disease, which more often than not manifests itself in persons who have had their primary infection (positive reactors to tuberculin) years before? I think we should still have to rely for early diagnosis on the awareness of the patient's relatives and the medical practitioner.

Dr. Tippet proposes a questionnaire for the consideration of the public, and unless I am being over-imaginative the framing of his questions appears to suggest that the public would have something here to smack its lips over. It is evident to all tuberculosis workers that the public is already superficially and embarrassingly informed in all aspects of the disease through the medium of the lay press, and much time has to be spent in correcting ill-digested impressions of a malady and its handling, which is, after all, a difficult and specialized matter.

The Ministry of Health's criterion for "arrest" of pulmonary tuberculosis demands a period of two years' "quiescence"; and a cured or "recovered" case must have been arrested for three years. The Ministry's caution in classifying a case as "recovered"—i.e., five years since the last symptom or sign of activity—truly indicates the uncertain outcome of this "foul" disease. It will be calculated, then, that a case discharged from a sanatorium in 1948 as "recovered" must have been continuously inactive since 1943, and an "arrested" case since 1945. Any sanatorium that claimed such cases would, with the present demand for a quick turnover, be an unusual institution. In reality, sanatoria have never aimed at anything curative beyond returning their patients home well set to continue their progress towards recovery. A few could be labelled "quiescent" on discharge.

So far as I am aware all cases discharged from public sanatoria in this country are regularly followed up by the local tuberculosis officer, and a good number of statistics on their progress have been compiled by local authorities and others. They tend on the whole to indicate that despite the good work of the sanatoria and the vigilance of the tuberculosis officers the poor man's home is, so far, not a very good environment for the ultimate cure of tuberculosis.

If, therefore, we cannot to-day afford sanatoria, then the need for a substitute is overwhelmingly urgent before we let loose on the community, as we did in 1939, all the potentially infectious inmates—many of them advanced chronic cases given refuge therein often for lack of anyone at home either willing or able to feed and nurse them. There is in all conscience enough tuberculous infection being spread about by lack of sanatorium facilities without our inviting an epidemic through hasty action. By all means let us welcome any new well-considered step in the prevention of tuberculosis, but in the meantime let no well-intentioned spanner be thrown into the groaning, though still working, machinery of the tuberculosis service.—I am, etc.,

Hereford.

T. V. R. PHILIP.

Diagnosis of Phthisis in General Practice

SIR.—Attention has been drawn by Dr. Peter Stradling (Nov. 6, 1948, p. 832) and Dr. Bertram Mann (Nov. 20, p. 917) to the practitioner's duty and delay in the diagnosis of phthisis. As one who has been specially interested in this condition I make the following comments with the hope that useful knowledge may be added for those who write such articles and have no sustained experience of general practice.

X Rays.—Hopelessly overworked departments have been the rule in most areas visited, and they are usually under-staffed; since the State Service came into being chaos has prevailed. How can one therefore send cases up—other than to a mass x-ray unit—for a host of suggested symptoms without considerable sifting? Shortage of films is another factor.

Cough.—Where this is found to be due to disease of the upper respiratory system, chronic bronchitis or heart failure, smoking to excess with or without alcohol, or secondary to acute infections, x-ray examination is *not* recommended unless the cough persists with other signs or symptoms. When one considers the huge numbers of cases of bronchial catarrh in the English climate, this can hardly be regarded as pathological; no x-ray examination is suggested for these. Dyspnoea and laryngitis are so common in non-tuberculous conditions that other causes should be eliminated first. Some four patients with tuberculous laryngitis have been seen in my practice in twenty-two years, two before the chest condition was diagnosed. Of the many pneumonias, a similar number proved to be due to phthisis.

Lassitude.—For every case found to be tuberculous in origin many hundreds are due to other conditions, especially functional causes.

Haemoptysis.—Whilst this indicates x-ray examination, many other conditions such as neoplasm, mitral disease, bronchiectasis, papilloma of bronchus, and acute bronchitis are commoner causes by far.

Pain in the chest, pleurisy, loss of weight, anorexia, and anaemia, while being symptomatic of tuberculous disease, so commonly occur in other conditions as often to rule it out without further thought. Ischio-rectal abscess, erythema nodosum, and phlyctenular conjunctivitis have become so increasingly rare for a number of years in my practice that as signs they seem remote compared with the commoner features. P.U.O. cases have mostly proved blanks to all investigations. Very few cases of influenzal and recurrent febrile chills have been found to be tuberculous.

Before condemning the practitioner in the delay of diagnosis of phthisis we must remember that there are other illnesses which take up his time. Any cough unaccounted for by multitudinous other causes and which persists for 2 to 4 weeks is investigated for phthisis by any reasonably modern or ancient competent family doctor, especially when accompanied by wasting, night sweats, and haemoptysis. Far too many criticisms are levelled at the family doctor by those who are quite ignorant of prevailing conditions of general practice, and what is more have no prolonged practical experience of this branch of medicine.—I am, etc.,

Hove, Sussex.

J. HARTSILVER.

Living Anatomy

SIR.—In the review of *Living Anatomy, a Photographic Atlas of Muscles in Action and Surface Contours* (April 2, p. 577), Professor H. A. Harris, discussing the platysma muscle, states, "This muscle is not figured." In point of fact, the platysma is shown with a photograph and title to itself in Fig. 8, p. 12.—I am, etc.,

Aberdeen.

R. D. LOCKHART.

B.C.G.

SIR.—Before we get carried away in our enthusiasm for spending large sums on B.C.G. vaccine and subjecting large numbers of helpless people to it, let us take note of one aspect of the matter that seems to have been ignored. What are the facts? We know that a person with a naturally acquired positive Mantoux reaction is not so likely to develop the disease when exposed to further doses of tubercle bacilli. But is not this only what one would expect in any case? After all, the

individuals with a positive Mantoux are those who—to use a biblical simile—have been tried in the fire and not found wanting. In other words, they have demonstrated that they already have an innate resistance to the disease, or they would not have survived to tell the tale. Obviously they will continue to show that resistance, and there should be nothing remarkable in that.

A naturally acquired Mantoux reaction, therefore, is merely a certificate, as it were, that they have successfully come through this ordeal; and in that sense it is, of course, of great value, say, in the selection of nurses. But does it follow that by inducing positive Mantoux reactions artificially, one can imitate that same degree of resistance? The Mantoux test itself does not confer the immunity but is merely a reported phenomenon. By analogy with other disease we can speculate that it may indicate resistance, but we can be by no means certain as yet. We know that the Mantoux reaction can be positive with the patient going steadily downhill; we also know that the dividing line between immunity and allergy in tuberculosis is a fine one. Until we have some really convincing proofs of the efficacy of B.C.G. let us remember that we are—I continue my metaphor in all seriousness—playing with fire. By all means let us have experiments, but let them be properly controlled ones with the full realization of the risks involved.—I am, etc.,

Fort Hare, Cape Province.

W. NORMAN TAYLOR.

Repetitive Auricular Flutter

SIR.—In a recent paper in this *Journal* (Jan. 1, p. 10) two of the undersigned (G.P.-S. and D.W.) reported a case of a boy who developed a cardiac dysrhythmia following contusion. The case was unusual in that an embolic hemiplegia had followed the contusion—the embolus presumably having arisen from a mural thrombus above the damaged endocardium. Electrocardiographic records which illustrated that paper were described as demonstrating an unusual example of heart block. We have heard from Dr. Cornelio Papp that the records were characteristic of repetitive auricular flutter,¹ and this opinion has since been confirmed by examination of a longer section of the record.

Dr. Papp's information is of particular interest, since repetitive auricular flutter is generally held to be a congenital arrhythmia, although there were good reasons for believing that in this case it followed a blow on the chest. As we were unable to find any other record of this aetiological association, we thought it desirable to correct the opinion which was expressed in the *Journal*, particularly in view of the fact that the mechanism responsible for the repetitive auricular flutter in this case was an unusual one.—We are, etc.,

GERALD PARSONS-SMITH.

DENIS WILLIAMS.

Diparcol in Parkinsonism

SIR.—I read with interest Dr. R. S. Duff's report (April 9, p. 613) dealing with the results of treatment with "diparcol" in some cases of Parkinson's syndrome, and consider that the details of the following case, which came under my care recently, are of sufficient interest to warrant publication.

A female patient, 57 years of age, developed encephalitis lethargica twenty years ago. Before diparcol was given she was unable to attend to the simplest personal duties, gait was markedly affected, and there was excessive salivation. Treatment commenced on Jan. 4, 1949. Initially, one tablet of 0.05 g. was given daily for three days, then later one tablet of the same size night and morning. The patient appeared to be very depressed, and salivation became more troublesome. On Jan. 25 the dosage was increased to three tablets of 0.05 g. daily, and *dextro-amphetamine sulphate* was also given three times daily one hour before the diparcol. Six days later a further increase to four tablets of 0.05 g. per day was made, and slight improvement followed. From this date dosage was progressively raised, until three tablets of 0.25 g. were being

given each day. On Feb. 22 there was a marked improvement: the patient was sleeping well, was able to use a knife and fork and do some housework, and had become much more cheerful. On March 1 five tablets of 0.25 g. were given daily, and this dose has been maintained ever since. Withdrawal of the dextro-amphetamine sulphate seemed to cause slight deterioration of the patient's condition, and for this reason it was continued. The patient can now cook for herself and can walk considerable distances. Before treatment her speech was almost unintelligible, but it has now, after diparcol therapy, become practically normal.—I am, etc.,

Wishaw, Lanarkshire.

OLIVER GRAY.

Amoebic Hepatitis

SIR,—The correspondence in the *Journal* on pre-suppurative amoebic hepatitis has just reached me here. From the evidence of the cases described there would appear to be no doubt that amoebic hepatitis can arise primarily in the British Isles, and this is not surprising, as it occurs in the U.S.A. in areas of similar climate. The correspondence, however, shows that the discovery of cysts morphologically resembling those of *Entamoeba histolytica* is still reported as clinching the diagnosis of amoebiasis. It is most unfortunate that this opinion is still widely held, as it was in the late war responsible for more unnecessary treatment in the Tropics than any other single factor.

Just as in the first world war the confusion of macrophages with vegetative entamoebae gave rise to a great deal of misdiagnosis, so in the late war the identification of yeasts and non-pathogenic cysts as *E. histolytica* led both to widespread incorrect treatment and to the disrepute into which the emetine treatment fell. It was also responsible for the introduction of the prolonged courses of ineffective polytherapy in the so-called cases of amoebiasis, which were sometimes apparently effective, since in many cases the patient never had the disease at all.

Dobell¹ estimated that 10% of the population of England, where the disease is a rarity, had *E. histolytica* cysts in their stools, and Craig² has stated that 95% of the population of the warmer States of the U.S.A. are infected. So the search for, or the discovery of, cysts in the stools is in reality a complete waste of time, and though the clinical accounts of the cases reported leave little doubt that the conditions described were of amoebic origin the discovery of cysts in the gut wall or in the stools was a finding of no importance. Amoebiasis, particularly in its chronic form, must be diagnosed clinically, and the laboratory is of little value, though this is undoubtedly one of the conditions where a therapeutic test with adequate emetine injections can be of the greatest value.—I am, etc.,

Nelson, New Zealand.

What is Normal?

SIR,—I think the letter of Dr. David Pyke (April 16, p. 682) under this heading should not go unchallenged. Exaggerated materialism has given rise to many unpleasant and reprehensible practices and much moral deterioration—as we know to our cost in this enlightened twentieth century—but I never expected to see an opinion put forward by a member of the medical profession such as that expressed by your correspondent.

Homosexuality used to be known commonly by a very different name and its indulgence recognized as a very unpleasant, immoral, and unnatural practice. Your correspondent suggests that it is not abnormal and "can hardly be regarded as a grave menace to social security." Apart from other considerations, a practice which runs counter to normal procreative activities must be considered abnormal; and, as regards the statement that it is not a menace to social security, the absence of moral control in its devotees and weakening of moral fibre associated with it is a sufficient answer.

I refuse to believe that "37% of all American males have homosexual experience after adolescence (and more before)," and, even if it were true, there is no reason for condoning this loathsome practice or suggesting its normality. It can only

lead to moral and, in the long run, to physical deterioration. In that sense it is a distinct menace to social security.

Those of us who have been to boarding school know of its existence among some of the degenerate, or immature and ignorant, youth of the nation and have seen some of its evil consequences. The fear of it has been an anxiety to many conscientious parents and schoolmasters, and it is incumbent on us all to try to help the young, by advice and example, to a better understanding of their impulses and the necessity of keeping them under control. Where responsible adult offenders are concerned, sterner measures for the repression of this odious vice, by classing it as a criminal offence, should be enforced.—I am, etc.,

Ditchling, Sussex.

W. BARRINGTON PROWSE

Shoulder-harness

SIR,—Having had the fortune to break a collar-bone for the third time, and having experienced the discomfort of strapping, plaster, and bandages—on the last occasion most carefully and efficiently applied by the surgeon according to Robert Jones's approved method and adjusted every two or three days in the beginning—the idea of the shoulder-harness occurred to me. It was carried out by the local saddler—Mr. L. O. Illsley—in one day.

The harness consists of two soft leather rings 2½ in. (6.4 cm.) wide, the circumference of which can be adjusted by a strap and buckle or by press-stud fasteners and need not be stitched; they are lined with sponge-rubber glued to the under surface of the leather with rubber solution and everted with a few stitches to fit comfortably in the axillae. Each ring has two buckles with runners from which the tongues have been removed to facilitate the sliding of the adjusting strap. The adjusting strap is of similar leather but not lined, about 60 in. (132 cm.) long, with a buckle at one end and a number of holes punched at the other end for adjustment as required. This strap is threaded through the runners as shown in the sketch. This device holds the shoulders back most efficiently and comfortably, and an ordinary arm sling may be worn in addition if considered necessary.

HARNES APPLIED

This device holds the shoulders back most efficiently and comfortably, and an ordinary arm sling may be worn in addition if considered necessary.

The advantages claimed for this harness are: (1) Its perfect comfort whether worn on the bare anatomy or preferably over a thin vest or shirt. (2) Its easy removal and reapplication by any person who may be assisting the patient in his or her toilet and dressing in the earlier stages of the disability, or even by the patient himself. (I was able to do this for myself after the third week.) (3) The rapidity with which it can be applied and adjusted without discomfort to the patient caused by the application of plaster or yards of roller bandage. Although my bandage was most efficiently applied, carefully padded with plenty of cotton-wool, and readjusted with infinite care every second or third day during the first fortnight, the cotton padding invariably lumped under the armpits and the bandage rucked up or slackened or chafed: this did not occur with the rubber padding, which retained its resilience even on sweaty occasions. I have ridden a push bicycle or a horse after the fourth week of the injury wearing the harness over my shirt, having applied it myself without any assistance.—I am, etc.,

Oakham.

H. J. MANOCKJEE CURSETJEE.

Complication of Podophyllin Therapy

SIR.—Since the appearance of the article by Mr. J. E. Semple entitled "Papillomata of Bladder Treated with Podophyllin" (June 26, 1948, p. 1235) a trial has been given to this form of treatment, using weekly instillations of 15 ml. of 4% podophyllin.

A woman, aged 63, was first seen in 1935, when she had three papillomata near the left ureteric orifice. During the next thirteen years she had regular treatment with perurethral diathermy. At cystoscopy on Aug. 16, 1948, a tiny seed-like recurrence high up on the left wall was seen. Five weekly instillations of 15 ml. 4% podophyllin were then given. The last instillation was on Dec. 16, 1948. Twelve days later the patient passed a mass about the size of a date stone *per urethram*, with considerable pain and difficulty. Analysis reports this to consist of podophyllin resin. On Jan. 5, 1949, the patient passed a further mass equal in size to the first. The weight was about 0.7 g. Each instillation of podophyllin contained 0.6 g. Approximately 50% of the podophyllin was therefore returned in the form of the calculi. Cystoscopy on Jan. 10 showed no evidence of further podophyllin. High up on the left side of the bladder three tiny papillomata were seen in a group about the size of a pin-head.

While there has been no apparent destruction of the growths by podophyllin, it was not for this reason that the treatment was adopted. It was felt that podophyllin may destroy the microscopic recurrences still not visible. It will therefore take several years to assess the ultimate value of such a course.

I should like to thank Mr. Hugh Donovan for permission to publish this case.

Teaching First Aid

SIR.—At the recent conference of first-aid workers and instructors held under the auspices of the ambulance department of the National Fire Brigades Association, some 150 delegates from all parts of Great Britain and Northern Ireland attended. Many of them were emphatic that the standard and teaching of first aid in this country are seriously handicapped by the inadequate number of doctors who are prepared to spare time for this purpose.

It is true that first-aid treatment ends where medical treatment begins and that many of us know very little about first aid. Yet we rely (especially those of us on the staff of a casualty hospital) even more than the general public do upon efficient first aid for those who are brought in under our care or are transferred by ambulance at our request.

It is therefore a disservice both to the public whom we serve and to our medical colleagues if we cannot find time—busy as we may be in these days—to take an interest in and instruct those (whether St. John, Fire Service, or other ambulance workers) who seek our help and guidance in this matter. The medical background which we doctors can supply to the practical common sense of first aid makes all the difference to the enthusiasm with which the subject is approached by those who learn it.

May I therefore appeal through your columns to those doctors who are approached by any organization for first-aid lectures or examinations to do their utmost to lend a helping hand and so encourage the voluntary spirit on which this sort of work must always rely?—I am, etc.,

F. J. CURTIS.

Redhill, Surrey.

Hon. Chief Surgeon,
National Fire Brigades Association.

Approach to the Frontal Lobes

SIR.—I am amazed at Dr. Max Valentine's enthusiastic support (March 5, p. 411) of Dr. Freeman's assumption that transorbital lobotomy cuts only the thalamic connexions of areas 9 and 10. Everyone who has some experience in experimental brain surgery knows the difficulty in producing a predictable lesion even under favourable circumstances.

I certainly do not want to belittle the neurosurgical work done in the past to alleviate mental illness, but it has always been a medical practice to give a specific indication for an operational intervention. The present state of frontal-lobe psychosurgery may be compared with the procedure of an abdominal surgeon who introduces a knife through a small abdominal incision in the hope of cutting certain portions of

the intestine and thus curing constipational trouble for which no organic basis can be found. No one would defend such a procedure, even if temporary relief were obtained, yet a similar procedure within the brain cavity seems to attract many followers.

I entirely agree with Dr. Valentine that appropriate teams in excellent collaboration are working in this field in the States. An example of critical teamwork can be found in a paper by the Connecticut Lobotomy Committee.¹ As Dr. Valentine has misunderstood my plea for this collaboration I would like to restate the main points of my letter (Jan. 29, p. 193)—namely, that further advances in the field of lobotomy can only be hoped for if the operational route chosen allows a clear assessment of the anatomical regions which have been undercut or removed. Only if one is reasonably certain about this can a correlation of psychiatric results and the operation be attempted. The desirability of this becomes obvious if one reads Freeman and Watt's remark that "each surgeon seems to have his own preference."

Dr. Valentine quotes the favourable results of Dr. Freeman's 100 cases started in 1946. It is certainly too early yet to draw definite conclusions from this material. A surgical intervention at the highest level of human personality—the frontal lobes (cf., Halstead's *Brain and Intelligence*, 1947, Chicago)—should be done with great caution, and only very critical evaluation of the results can lead to progress and prevent disappointment in a method which raises high hopes at present. I do not want to deliver a counterblast to psychosurgery, as Dr. Valentine suggests; I only maintain that this branch of neurosurgery is still in an experimental stage and any new blind approach will delay the understanding of the underlying mechanism of mental recovery after lobotomy.—I am, etc.,

Oxford.

Injury Caused by Ear-rings

SIR.—The following case is reported on account of its rarity.

A young lady, aged 23, complained that the lobes of both ears had been severed following the use of spring ear-rings. The photograph shows the condition of one ear. The other was similar. She stated that she had been in the habit of wearing stud ear-rings which fastened on with spring clips. She never noticed any unusual pain or discomfort, but after wearing the ear-rings for some weeks without removing them (exact time unknown) she found them difficult to take off. When they were taken off she found the ears had sloughed under the clips. Both ears healed rapidly, but she felt they were so unsightly that she did not go out in public without her head and ears being covered. Surgical repair was easily accomplished.

Ear-rings of this type are in universal use. The lobes of the ears are insensitive, and damage can occur without noticeable discomfort unless such clips are removed frequently.—I am, etc.,

Dublin.

Diathermy Prong Forceps

SIR.—Mr. A. Wilfrid Adams (April 9, p. 631) has added a new diathermy appliance to our list of special instruments. I have always been interested in the surgical uses of diathermy, and I have described¹ how any instrument may be used for diathermy by simply soldering to a convenient spot on it a length of ordinary electric flex. (Stainless-steel instruments cannot be soldered.)

Since writing that paper I have found that it is unnecessary to solder the lead to the instrument. Two inches (5 cm.) of insulation is removed from a piece of lamp flex and the bare wire is then fixed to the instrument by winding and held in position by covering the union with surgical adhesive tape. If

Obituary

J. R. CURRIE, M.D., F.R.C.P.Ed.

John Ronald Currie, who was the first professor of public health at Glasgow University, died in Edinburgh on April 13 at the age of 78. Professor Currie had retired from the chair in 1940, but until just about a year ago he had retained the posts of medical officer of health for the county of Bute and the burgh of Rothesay, thereby completing almost a half-century in the field of public health. His emergence as a teacher came only in 1922, when he accepted the chair of preventive medicine at Queen's University, Kingston, Canada. A year later the Henry Meckan chair of public health was founded at Glasgow, and Currie returned to Scotland to be its first occupant. His early academic training reflected that scholarly and humanistic approach to medicine—so rare nowadays—which was to mark his later life. After receiving his early education at Ayr Academy Currie went to Edinburgh University, to graduate M.A. there in 1891. A period at Oxford followed, and he obtained first-class honours in Classical Moderations, taking his B.A. in 1896. Returning to the West of Scotland, he studied medicine at Glasgow and won many distinctions as a student, graduating in 1898 with commendation. He took his D.P.H. from Birmingham in 1904.

During the early 1900's the fever hospital at Belvidere in Glasgow had as its physician superintendent Dr. John Brownlee, who collected round him a group of men most of whom were later to make their own reputations in the public health service. At that time to be chosen as one of Brownlee's residents was itself a mark of distinction. Currie came under his influence in 1905, and in the succeeding few years he made his first contributions to medical literature, writing a number of scholarly papers on the new subject of serum disease. In 1910 he presented for the M.D. a thesis which was highly commended. It was on this firm foundation of experience in infectious diseases, then so important to a public health career, that he proceeded to build further practical knowledge from posts at Stirling, Dumbarton, Chester, and Fife. During the first world war Currie served as a sanitary specialist in the R.A.M.C., returning to Scotland to work with the Board of Health, which later became the Department of Health for Scotland. Such a breadth of practical experience, added to his earlier classical education, made an academic career a natural choice. It may have been something of an accident that caused Canada to be the scene of his first teaching post, but it was most appropriate that he should return so speedily to his old medical school. He was elected F.R.C.P.Ed. in 1934, and on his retirement from the chair he received the honorary degree of LL.D. For many years he was a valued anonymous contributor to this *Journal*.

It was easy to overlook Professor Currie's many excellent qualities. Naturally shy and retiring, his erect, rather soldierly appearance made him a somewhat forbidding figure to his students. But the stern exterior was an easily displaced mask behind which lay a sense of the absurd which would emerge to reveal a very lovable personality. His mind, nurtured on a course of "fine, confused feeding," had that richness which comes from a reverence of the classics; and his breadth of outlook was best appreciated in after-dinner conversation.

FELIX D'HERELLE, M.D.

Professor Felix d'Herelle, who was well known for his work on bacteriophage, died in Paris on Feb. 22.

Felix d'Herelle was born at Montreal, Canada, in 1873 of French-Canadian parentage, and though he retained throughout life his British nationality, of which he was always proud, he gave to his acquaintances the impression of being rather more French than British in temperament and outlook. Educated at the Lycée Louis le Grand, Paris, he took his baccalaureate in 1888, and then returned to his native Canada to study medicine, and graduated M.D. at Montreal. He was professor of bacteriology at Guatemala from 1901 to 1907, and bacteriologist to the Mexican Government for the next two years. He joined the staff of the Pasteur Institute in Paris in 1909. There he was *chef de laboratoire* from 1914 to 1921. During these years his services were often at the disposal of foreign Governments.

Thus he went on special missions to the Argentine in 1911-13, Turkey in 1914, Tunis in 1915, and to Indo-China in 1921. After leaving the Pasteur Institute, d'Herelle went to Leiden University, Holland, as professor extraordinary in 1922. Two years later he was appointed to the International Quarantine Council, Egypt, as director of the laboratory service, which was based on Alexandria. There he remained until 1926, when he went to India on a special mission at the request of the British Government. He was appointed professor of protobiology at Yale University in 1928, retiring from that post in 1933 in order to found his Bacteriophage Laboratory in Paris. In the years that followed he was entrusted by the Government of the U.S.S.R. with the setting up of bacteriophage research institutes at Tiflis, Kiev, and Kharkov.

It was in 1917, in a note to the French Academy, that he published his observations, "Sur un Microbe Invisible, Antagoniste des Bacilles Dysentériques." The phenomenon of bacteriophage had been discovered earlier by Twort (1915), who spoke freely of it during his war service, but the graphic description given by d'Herelle, and his insistence that he was dealing with what is now recognized to be a virus, startled the scientific world, and the importance of his findings was immediately appreciated. He received many honours. Doctorates were conferred upon him by the Universities of Montreal, Quebec, Yale, Leiden, Tiflis, and Bakou. He was an honorary member of several learned societies—the Royal Society, Canada; the Société de Biologie, Paris; the Société de Microbiologie, Leningrad; and the Scientific Club, Winnipeg. But he was specially proud of the Loewenhoeck Medal of the Académie des Sciences, Amsterdam, which he was awarded in 1925. The only French scientist to have received this distinction before d'Herelle was Louis Pasteur.

Of d'Herelle's better-known English writings, mention may be made of "Immunity in Natural Infectious Disease" (1924), which was followed by "The Bacteriophage and its Behaviour" (1926), "The Bacteriophage and its Clinical Applications" (1930), and "Studies on Asiatic Cholera," the latter in conjunction with Malone (1930). His most important writings in French were: "Le Bactériophage, son Rôle dans l'Immunité" (1921); "Les Défences de l'Organisme" (1923); "Le Phénomène de la Guérison dans les Maladies Infectieuses" (1938); and *Étude d'une Maladie: le Choléra, Maladie aux Paradoxes* (1948). A clear thinker, with an impeccable laboratory technique, and endowed in high degree with the logical outlook of his race, d'Herelle appeared at times somewhat intolerant to those who differed from him. Yet to his friends and associates he was one of the kindest and most loyal of men.

Dr. ARTHUR ERNEST WHITEHEAD died at Bridlington on March 13 at the age of 75. Educated at University College, Sheffield, he qualified in 1900, and after the usual house appointments and a short period in practice at Almondbury he settled in Bridlington in 1905. He soon built up an extensive practice and became prominent in the social life of the town. He served the Lloyd Hospital for forty-four years as a medical officer on the staff and as a member and later chairman of the board of management. Dr. Whitehead had many interests. He was a keen yachtsman and an active freemason. After his retirement from practice in 1938 he was elected a member of the East Riding County Council, and he became a J.P. and acted for some years as chairman of the juvenile court. During the 1914-18 war he served in the R.A.M.C. at Salonika, and in the 1939-45 war he was in charge of the civil defence scheme for Bridlington. Dr. Whitehead's interest in mankind—especially the local variety—remained with him to the end, and confinement indoors he found a sore trial. He must have known and been known by nearly everyone in the East Riding, and his short, stocky figure and cheerful smile were very much part of the local scene. He leaves a widow, two sons, and a daughter, and to them the sympathy of his colleagues and friends will be extended. Both sons were awarded the Military Cross in the recent war.—C. J. G. T.

FRANK GRIFFITH THOMAS, who died at his home at Bournemouth on March 22 at the age of 76, was a native of Swansea and a son of Dr. Jabez Thomas, the founder of the first eye hospital in that town. He succeeded his father as ophthalmic surgeon to the Swansea General and Eye Hospital in 1900. He remained in Swansea until about eighteen months ago, when he retired because of ill-health, which unfortunately left him unable to enjoy to the full a well-earned rest. Frank Thomas

graduated M.B., B.Ch. in 1897. He was a student at Cambridge and at Guy's Hospital, where he became house-physician and clinical assistant. He was also clinical assistant at the Royal London Ophthalmic Hospital, and later registrar at the Royal Eye Hospital. After studying in Vienna he returned to Swansea, and was the ophthalmic surgeon to the hospital there until 1924, when he was appointed consulting ophthalmic surgeon. He was also ophthalmic surgeon to the Gorseinon, Aberdare, Port Talbot, and Brecon hospitals as well as to the Swansea Institution for the Blind, the Cambrian Institution for the Deaf and Dumb, and the Orphan Home. In addition, Thomas was an ophthalmic medical referee for the South Wales courts and for the Ministry of Pensions. During the 1914-18 war he held the rank of captain in the R.A.M.C., and in the last war he took his full share of responsibility in the E.M.S. As Swansea suffered badly from air raids this meant a great deal of work for a man of advancing years, but he never shirked it. Frank Thomas was an ophthalmic surgeon of exceptional ability, and his knowledge of ophthalmology, and of medicine in general, was profound. He was a man whose opinion on difficult eye conditions was always worth having, and, apart from his large experience and his love for the subject of ophthalmology, he had an almost uncanny flair for spotting the cause of, and for knowing the best treatment for, many puzzling diseases. He was one of the originators of the Oxford Ophthalmological Congress, and he was a vice-president of the Ophthalmological Section when the Annual Meeting of the B.M.A. was held in Swansea in 1928. His wide experience of compensation cases, in which he reported with strict impartiality, made his findings of great value to both employers' and workmen's representatives. Frank Thomas was good at games, and rowed for Caius while an undergraduate. His golf was sound, and he also played a very good game of billiards and excelled at croquet. Frank Thomas was very fortunate in meeting his future wife when she, a doctor's daughter and a doctor herself, was a resident at the Swansea Hospital assisting him in the eye department. Throughout his life she looked after his welfare devotedly, and in addition was able to assist him at his work, being on the honorary staff of some of the hospitals he visited. He survives him with two daughters and two sons, one of the sons being an orthopaedic surgeon in Hereford and the other an ophthalmic surgeon at Bournemouth. Although Frank, as his friends knew him, or "Dr. Frank," as his patients affectionately called him, has passed away, his memory will always remain green in Swansea and, indeed, in South Wales. To work with him was a privilege.—R. T.

H.E.Q. writes: Frank Thomas was a skilful diagnostician and an accomplished operator. He will long be remembered by his colleagues on the hospital staff and by general practitioners in South Wales as well as by his patients for his ready help and advice. Outside his professional work his chief interest for many years was golf, and he was closely associated with the development of Pennard Golf Club from its earliest days until a few years ago, when failing health put an end to his active participation in the game.

Dr. HAROLD WACHER, who died on April 11 after a long illness, was the son of a well-known physician. He was born in Canterbury in 1876, and educated at the King's School, Canterbury, St. John's College, Cambridge, and Guy's Hospital. He joined his father in practice in Canterbury shortly after he graduated M.B., B.Ch. in 1903. Apart from service in Egypt and France from 1914 to 1918, he practised continuously in Canterbury until the onset of his illness nearly two years ago. For many years Dr. Wacher was senior physician at the Kent and Canterbury Hospital, and he worked hard at the planning and financing of the new hospital which was opened in 1937. He also served as poor-law officer and medical officer to the municipal hospital, Canterbury, from the time of his father's retirement. A born actor, he was well known at Guy's in the "Disguised Minstrels" and as one of the founders of the residents' play. He was even better known in Canterbury for his acting with the "Old Stagers" in the last forty years. As an antiquary and a fellow of the Society of Antiquaries he had studied the history of Canterbury, and he wrote his M.D. thesis in 1928 on the medical history of Canterbury. To a wide circle of friends he was a lavish entertainer, and his good fellowship and his artistry as a raconteur and after-dinner speaker made him welcome at many social gatherings. Canterbury has lost a good friend and servant and one who did a great life's work in practical medicine, in common humanity, and in lightening the lives of his fellows with good humour and laughter.

Dr. FOSTER COATES died at the age of 68 at his home in Belfast on March 23. The son of Dr. Stanley Coates, he was educated at the Methodist College and Queen's College, Belfast. He graduated B.A. in 1900, M.B., B.Ch., B.A.O. in 1905, and succeeded M.D. in 1907. He took the D.P.H. in the same year,

also in the Royal University of Ireland. He was an R.M.O. and afterwards a registrar at the Royal Victoria Hospital, and on his return in 1919 from active service in France he was appointed an assistant physician. He was also for some years a visiting physician to the Forster Green Hospital for Diseases of the Chest. In 1946 Foster Coates was elected an honorary consulting physician to his old hospital, which he had served so faithfully for over forty years. An active member of the B.M.A., he was president of the Ulster Branch in 1928-9, and vice-president of the Section of Medicine at the Belfast Meeting in 1937. He was also a member of the Association of Physicians, and in 1935-6 was president of the Ulster Medical Society. Dr. Coates was a lecturer in clinical medicine in the Queen's University of Belfast and a member of the Senate. A sound physician with a greater love for purely clinical than for laboratory or even radiological methods of diagnosis, he gained the respect and affection of generations of house-physicians and students, who quickly appreciated his integrity and his acumen. These qualities were much valued by his Majesty's judges and members of the legal profession when he gave evidence in many medico-legal cases, particularly under the Workmen's Compensation Acts. Those who were his colleagues will not soon forget his kind heart and unselfish comradeship. He is survived by his widow, two sons, and a daughter.

SARAVANAMUTTU THAMBIAH, who died on Feb. 18, was born in Ceylon in 1891. After taking his B.A. at Madras University in 1913 he entered the Medical College there and qualified in 1917. He served in the Army from 1918 to 1926 and was awarded the Military Cross. Until 1929 he was lecturer in materia medica at the Stanley Medical School, Madras, and then he came to Britain to continue his studies. Dr. Thambiah took the Scottish triple qualification in 1929 and the Edinburgh M.R.C.P. a year later. Returning to India, he was appointed professor of medicine at the Prince of Wales Medical School at Tanjore, and six months later was posted to the Government General Hospital at Madras as lecturer in dermatology and physician in charge of the skin department. He was responsible for the organization of this clinic, which he raised to a very high standard of efficiency. In 1940 he was made an additional professor of medicine at the Madras Medical College, and in 1945 professor, though he still continued to hold the post of dermatologist to the Government General Hospital. In recognition of his services he had conferred on him in 1945 the title of Rao Bahadur. A year later he left the service on completing his fifty-fifth year, and led a quiet life in retirement, though continuing his consulting practice in Madras. In October, 1948, he was elected F.R.C.P. Ed., and shortly afterwards his final illness began. Dr. Thambiah's popularity was such that he was consulted by patients from the north of India, Malaya, and Ceylon. His untimely death at the age of 58 leaves a gap which it will be difficult to fill. He is survived by his widow, two daughters, and a son.

Medico-Legal

DEATH FOLLOWING TREATMENT WITH DICOUMAROL

What seems to be one of the first cases of death following the administration of dicoumarol to be considered by a coroner's court was reported recently. The evidence was heard by the Battersea coroner, Dr. R. B. Hervey Wyatt, on April 4.

A woman of 70 went to her doctor on March 7, 1949, complaining of pain in her left leg. Her general practitioner, in his evidence, said that he found a deep thrombosis of the left femoral vein from the calf right up to Poupert's ligament. He ordered her to stay in bed and gave her some glycerin and belladonna paint. He also left a prescription for 100 tablets of dicoumarol and told her to take six tablets on the first day and then four tablets daily.

On March 14 the patient was restless and excitable, so he told her to discontinue the glycerin and belladonna paint and to take only two tablets of dicoumarol a day. The doctor said that the dose he ordered was that recommended by the makers, and he also consulted the *British Encyclopaedia of Medicine*. He had used the drug on four other cases in a similar dosage, and in one of them for 16 days without ill effect. He did not recall hearing of the danger of the drug or that its effect should be checked by examinations of the patient's blood.

On March 26 he saw the patient again, diagnosed renal colic, and sent her into hospital. She had had severe pain in the left

Medical Notes in Parliament

Hospital Endowments Commission

The Secretary of State for Scotland announced on April 14 that Professor Sir Sydney Smith, dean of the Faculty of Medicine at Edinburgh University, had been appointed chairman of the Hospital Endowments Commission. Dr A. Greig Anderson, of Aberdeen, who is a member of the North-Eastern Regional Hospital Board, is the only medical member. The Hospital Endowments Commission is a purely Scottish body. There is no corresponding body under the National Health Service in England and Wales.

Clinical Details Confidential

Mr JOHN LEWIS reported on April 14 that the senior administrative medical officer of the Manchester Regional Hospital Board had advised the secretary of the Bolton Hospital Management Committee that if medical officers of health asked for information about patients discharged from hospital and in need of aftercare only the address need be given.

Mr BEVAN replied that the Board had encouraged management committees to co-operate fully with local authorities but had rightly advised them not to disclose to them clinical details of patients, which should generally be treated as confidential.

On the same date Mr LEWIS further asked whether Mr Bevan knew that the senior administrative medical officer of the Manchester Regional Hospital Board had instructed medical officers at venereal disease clinics in the area that information about patients attending the clinics should not be disclosed to medical officers of health, even if requested for purposes of contact tracing. Mr Lewis said that medical officers of health in all parts of the country had always had free access to information about patients.

Mr BEVAN answered that the Regional Hospital Board had rightly taken this step to ensure that the statutory regulation about the secrecy of V.D. treatment was scrupulously observed.

Private Practice

On April 14 Dr SEGAL asked whether Mr Bevan was aware that medical practices were still advertised by private agencies for sale and purchase, and what steps he proposed to take to put an end to this practice. He further asked if Mr Bevan could make arrangements to establish official agencies for the transfer of medical practices, partnerships, and assistantships.

Mr BEVAN said there was no prohibition on the sale and purchase of purely private practices. He saw no objection to such transactions being handled by private agencies. The transfer of practices and the introduction of new partners and assistants in the National Health Service were already controlled by the appropriate official bodies.

Industrial Injuries Special Hardship Allowance—The Minister of National Insurance, Mr JAMES GRIFFITHS, has laid before Parliament regulations which enable the special hardship allowance provided under the National Insurance (Industrial Injuries) Act to be paid with industrial disablement gratuities whatever the period for which the disablement has been assessed. The new regulations came into operation on April 13. Previously the allowance could only be paid with a disablement gratuity based on an assessment of disablement for a period of over two years. This special hardship allowance is an allowance of up to 20s a week which can be paid with an industrial disablement pension or gratuity if the disabled man or woman is unable to return to his regular occupation and cannot work at a job of a similar standard.

Vaccination—Mr BOSWELL inquired on April 14 what was the approximate proportion of the population now vaccinated as compared with that which was immunized against smallpox before the last war. Mr BEVAN answered that records were available up to 1946 at present, only on infant vaccination. These showed that about 42% of children born in 1946 were vaccinated in infancy as against about 34% in 1938.

The Samuel Kress Foundation has given about £2,000,000 to the New York University Bellevue Medical Centre for the development of postgraduate medical education on a national and international scale. The Kress Foundation stated "Privately financed medical education is more effective, more economical, and more in keeping with the essential tradition of American democracy, now subject to a radical challenge in our country and throughout the world, than Government financed medical education." Mr Kress is the founder of a chain of stores.

EPIDEMIOLOGICAL NOTES

Smallpox

The period of surveillance of passengers and crew of the *s.s. Mooltan* ended on April 19. The total of confirmed cases of smallpox arising from the first fatal case on board is 11. Four of the fatal cases were in persons who were unvaccinated at the time of infection the fifth being a man of 61 who was vaccinated in infancy. In other cases there is evidence that vaccination has produced considerable modification of the disease, and this has sometimes given rise to difficulty in diagnosis. It is advisable that all contacts showing doubtful lesions should be isolated for observation and bacteriological examination. Contacts with such signs have been admitted to hospital from Southwark, Sutton and Cheam, Romford, St Pancras, and West Ham. Up to April 25 there has been no confirmation of the diagnosis of smallpox in any person who was not on board the *s.s. Mooltan*. Further clinical observation and laboratory investigation have removed any suspicion that the two patients in Lacey Smallpox Hospital mentioned last week (April 23, p. 732) are suffering from smallpox.

Influenza

The number of deaths provisionally ascribed to influenza in the 126 great towns in the week ended April 16 was 95 compared with 192 in the preceding week. The peak figure of 360 deaths was reached in the week ended March 19, and since then there has been a fairly rapid decline. Notifications of acute primary and influenza pneumonia reached a peak of 918 cases in the week ended March 12 and have since declined to 522 in the week ended April 9.

No further reports of outbreaks have been received recently, and it would appear that the outbreak of virus influenza is now over. It was characterized by a high incidence in the Midlands and North, with, however, a low fatality rate. In several outbreaks a strain of virus A nearly related to the strain isolated in this country in 1947 was found. There were also a few isolations of virus B from outbreaks in semiclosed communities.

First Quarter of 1949

The number of stillbirths registered in England and Wales during the first quarter of 1949 was 4,418 giving a rate of 23.1 per 1,000 total live and still births, the lowest rate ever recorded for a March quarter in this country. For the same period a year ago the rate was 24.3, and there has now been a progressive fall in the rate for the first quarter for the past nine years.

The number of deaths of children under 1 year of age was 7,462, representing a record low rate of 40 per 1,000 related live births. This compares with the previous record of 41 in the corresponding quarter a year ago and 55 in the March quarter of 1947.

There was again a fall in the number of live births registered in England and Wales. For the March quarter of 1949 the figure was 186,561 compared with 202,184 in the March quarter, 1948, and 241,530 in the first quarter of 1947. The corresponding rates per 1,000 total population were 17.4, 18.7, and 22.8 respectively. In the following table the numbers of live births, stillbirths, total deaths, and deaths of infants under 1 year of age registered in the March quarter, 1949, and the corresponding rates are compared with those for the March quarters 1948, 1947, and 1938.

	Live Births		Stillbirths		Deaths (including Non-civilians)		Deaths of Infants under 1 Year	
	Number	Per 1,000 Total Population	Number	Per 1,000 Total Live and Still Births	Number	Per 1,000 Total Population	Number	Per 1,000 Related Live Births
1st Quarter, 1949	186,561	17.4	4,418	23.1	161,279	15.0	7,462	40
" " 1948	202,184	18.7	5,043	24.3	152,708	12.3	8,358	41
" " 1947	241,530	22.8	6,347	25.6	181,716	17.1	12,561	55
" " 1938	155,187	15.3	6,185	39.3	137,597	17.6	10,545	69

Discussion of Table

In England and Wales infectious diseases were less prevalent during the week. There were decreases in the notifications of measles 1,095, acute pneumonia 388, whooping-cough 390, and scarlet fever 66.

The largest decreases in the notifications of measles were Yorkshire West Riding 326, Middlesex 240, Essex 223, Staffordshire 177, Surrey 171, Lancashire 164, and Glamorganshire 101; the largest increases were London 266, Derbyshire 134, Warwickshire 101, and Hertfordshire 76. In most areas the incidence of whooping-cough was unchanged, the decline being due to the experience of a few counties, notably Lancashire 101, Kent 79, and London 76.

There were decreases in the notifications of scarlet fever in Essex 31 and London 22. The chief feature of the returns for diphtheria was an increase of 9 in the notifications in Durham. The decrease in the incidence of acute pneumonia was general throughout the country.

An outbreak of dysentery affecting 10 persons was notified in Norfolk, Norwich C.B.; other large returns were London 11, Yorkshire West Riding 11, and Lancashire 10.

In *Scotland* a decrease was recorded in the notifications of whooping-cough 54, measles 10, and diphtheria 9. There was an increase in the incidence of acute primary pneumonia 23. Of the 23 cases of dysentery 20 were notified in Glasgow.

In *Eire* there were increases in the incidence of measles 40 and scarlet fever 28, and a decrease of 10 was recorded in the notifications of whooping-cough. Notifications of diarrhoea and enteritis in Dublin C.B. were 10 fewer than in the preceding week.

In *Northern Ireland* increases were reported in the notifications of measles 42 and whooping-cough 40. The largest increases in the incidence of measles were in County Down 24 and County Tyrone 21. A rise of 25 in the notifications of whooping-cough was also recorded in County Down.

Corrected Notifications

Corrected notifications have been given in the quarterly reports of the Registrar-General since the June quarter of 1944. These show, except in the case of diphtheria, that the proportion of diagnostic errors has remained fairly constant over this period. In the notifications of diphtheria, however, there has been a continuous increase in the proportion of errors. Corrected notifications amounted to three-quarters of the original notifications in 1944, but to only two-fifths at the end of 1948. Of the other common infectious diseases of childhood, measles and whooping-cough have a negligible diagnostic error and scarlet fever an error of about 2%. The corrected notifications of cerebrospinal fever recorded as a percentage of the original notifications ranged from 53.6 to 84.5 during the period. During the epidemic of acute poliomyelitis in the third quarter of 1947 there was an error of 20% in the notifications, which increased to 30% in the second quarter of 1948.

Corrected Notifications Expressed as a Percentage of the Original Notifications

Year	Qtr	Scarlet Fever	Diphtheria	Enteric fever (Typhoid and Paratyphoid)	Acute Pneumonia	Dysentery	Cerebrospinal Fever	Measles	Whooping-cough	Acute Poliomyelitis

Week Ending April 16

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,039, whooping-cough 2,267, diphtheria 103, measles 13,066, acute pneumonia 731, cerebrospinal fever 27, acute poliomyelitis 5, dysentery 49, smallpox 7, paratyphoid 1, and typhoid 2.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 9.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week of the year 1948 are given for: (a) England and Wales (London included), (b) Scotland, (c) Eire, (d) Northern Ireland, and of Deaths recorded under each infectious disease, towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Medical News

British Journal of Urology

The *British Journal of Urology* celebrates its coming-of-age with important editorial changes. Mr. H. P. Winsbury-White, who has edited the journal since its beginning in 1929, at first in collaboration with the late Frank Kidd and later with the assistance of Mr. A. E. Roche, has retired from the editorial chair to become consulting editor. Mr. David Band will in future edit the journal, assisted by Mr. J. D. Fergusson and Mr. N. M. Matheson, and supported by an editorial committee drawn from all parts of the Commonwealth. The journal will in future be published by Messrs. E. and S. Livingstone, of Edinburgh, and will include original papers from urologists in Britain and the Commonwealth. The issue of the journal for March, 1949, which appears under this new regime, incorporates several improvements in style, with a very high standard of production. The valuable abstracts from current literature and the index of current urological literature appear as usual. The British Association of Urological Surgeons, which was formed in 1945, adopted the *British Journal of Urology* as its official publication in 1946, and its support should assure the future of the journal. British urologists owe a debt of gratitude to Mr. Winsbury-White for his most able editorship for a period of 20 years, as also to Mr. Roche, who has assisted him for the past 15 years.

National Formulary

The *National Formulary* comes into operation on May 1. The Ministry of Health is anxious that the use of the *N.I.F.* and the pre-war edition of the *N.F.* should be discontinued. The use of old titles which differ from those in the new *N.F.* will inconvenience the chemist and may necessitate reference back to the doctor. It will be a help if all formulae which are not *B.P.*, *B.P.C.*, or *N.F.* are written out in full by the prescriber. Where a formula preparation is being prescribed the new *N.F.* should be used. No formula for linctus diamorphinae is included in the new *National Formulary*. From May 1, a prescription for linctus diamorphinae *N.I.F.* described by title does not meet the requirements of the regulations under the Dangerous Drugs Acts, and where the preparation of the *N.I.F.* is required the formula must be written out in full. The Ministry of Health has announced that, in agreement with the medical profession, where linctus diamorphinae or linctus diamorphinae *N.I.F.* is prescribed by title the new linctus diamorphinae of the *B.P.C.* will be dispensed.

New Radiographic Department at Queen Square

The chairman of the National Hospital gave a dinner on April 5 at the Staff Residence in celebration of the opening of a new radiographic department on the third floor of the building in Queen Square. Among the guests were Dr. S. Cochrane Shanks, consultant adviser in radiology to the Ministry of Health, and Dr. Cecil Teall, President of the Faculty of Radiologists. In a speech after dinner, Dr. Erik Lindgren paid tribute to Dr. Erik Lysholm, of Stockholm, the celebrated neuro-radiologist, who planned and designed the layout of the new radiographic floor. "His tragic death a few weeks after the plans were finished," he said, "robbed medical science of one of its outstanding figures." Dr. Lindgren succeeded Dr. Lysholm as head of the Radiological Department at the Seraphimer Hospital in Stockholm and assisted him in the design of the National Hospital's new department. In thanking all who helped in bringing the scheme to fruition Dr. Hugh Davies, President of the British Institute of Radiology and radiologist to the National Hospital, paid a special tribute to Mr. Shönander, who co-operated with Dr. Lysholm in the manufacture of skull table apparatus. He supplied four, as requested, but would accept payment for only three. He presented the fourth to the National Hospital in memory of his great friend, Dr. Lysholm.

COMING EVENTS

Edinburgh Lectures

In connexion with the postgraduate courses in medicine and surgery a series of open lectures on subjects of wide biological interest will be given during the summer term in the Anatomy Lecture Theatre, University New Buildings, Edinburgh. The first lecture was given by Sir James Learmonth on April 19, on "Reflections on Portal Hypertension." Details of the remaining lectures to be given on May 3, 17, and 31 and June 7 and 21 will be published in the diary column of the *Journal* week by week. All graduates and students are invited to attend the lectures.

Tropical Medicine Course at McGill

A course for the Diploma in Tropical Medicine and Hygiene at McGill University will start in October. Applications should be received by June 1 by the Dean of the Faculty of Medicine, McGill University, Montreal, P.Q., Canada.

Hospital Administrators

The Annual Conference of the Institute of Hospital Administrators will be held at Southport on May 6-7. Papers to be read include "Administrative Problems of the Hospital Service" and "Hospital Development—Present and Future." Information may be obtained from the Secretary of the Institute at Tavistock House North, Tavistock Square, London, W.C.1.

Marriage Guidance Conference

The National Marriage Council will hold a conference, a counsellors' training course, and the annual general meeting at the Esplanade Hotel, Belmont Road, Scarborough on May 14-21. Subjects to be discussed at the conference include sex education, the divorce law, and artificial insemination. Particulars may be obtained from the Conference Secretary, National Marriage Guidance Council, 78, Duke Street, Grosvenor Square, London, W.1.

Hospital Chaplains' Conference

The Annual Conference of the Church of England Hospital Chaplains' Fellowship will be held at St. Edward's House, 22, Great College Street, Westminster, S.W.1, on May 17-18. Clergy doing hospital work will be welcome whether they are members of the Fellowship or not. Information may be obtained from the Rev. J. Gordon Cox, Horton Hospital, Epsom, Surrey.

West London Medico-Chirurgical Society

The annual banquet of the West London Medico-Chirurgical Society will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., on Wednesday, May 18, at 7.30 p.m. for 8 p.m. The Triennial Gold Medal will be presented by Lord Moran to Professor R. A. McCance, F.R.S., Professor of Experimental Medicine, University of Cambridge. The Right Hon. Sir Norman Birkett, P.C., and the Right Hon. the Lord Burghley will also speak.

Conference of M.O.s.H.

The County Borough Group of the Society of Medical Officers of Health will hold their annual meeting and conference under the presidency of Dr. R. M. Galloway (Bolton) at "Low Wood," Windermere, on May 6-9. The programme includes talks on "The Working of the National Health Service Act, 1946," by Drs. C. Metcalfe Brown and John A. Guy; on maternity and child welfare; by Mrs. Baker, formerly Matron of St. Mary's Hospital, Manchester; on "Mental Health Service Responsibilities of Part III Authorities under the National Health Service Act, 1946," by Dr. W. Rees Thomas, Ministry of Health; on "The Care of the Deaf in the Community," by Drs. A. W. G. and Irene Ewing; on "The Training of Health Visitors," by Professor I. G. Davies; and on "Medicine—Social and Anti-social—in West Africa," by Professor Andrew Topping. The honorary secretary is Dr. J. Greenwood Wilson, of Cardiff.

Professor J. C. Spence

Professor J. C. Spence, Nuffield Professor of Child Health at Newcastle-upon-Tyne, has been appointed by the President and Fellows of Harvard College as Cutter Lecturer in Preventive Medicine for 1948-9, and will visit Boston to deliver the lecture on May 11. He will serve also as Visiting Physician-in-Chief for a week to the Boston Children's Hospital, and then travel to Canada to deliver the Blackader Lecture in the general session at the Annual Meeting of the Canadian Medical Association in Saskatoon.

Charities Ball

A Charities Ball organized by the Metropolitan Counties Branch of the B.M.A. will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Thursday, May 26, at 8 p.m. for 8.30 p.m. The proceeds will be devoted to medical charities in urgent need of support. Patrons include the President of the Association and the Presidents of the three Royal Colleges. There will also be a cabaret and facilities for bridge. The cost of tickets including a buffet supper is two guineas each. Applications should be sent to the Secretary, the Charities Ball Committee, Metropolitan Counties Branch, B.M.A. House. Contributions to charities from those unable to attend the ball would also be most welcome and should be sent to the same address.

SOCIETIES AND LECTURES

Monday

EDINBURGH UNIVERSITY.—At Physiology Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, May 2, 5 p.m., "The Value of History in Medicine," by Dr. Douglas Guthrie.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 2, 5 p.m., "Congenital Defects of the Kidney and Ureter," by Mr. J. G. Sandres.
LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, W.C., May 2, 4.45 p.m., "Selective Toxicity with Special Reference to Chemotherapy," by Professor Adrien Albert.

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, University New Buildings, May 3, 5 p.m., "Anticoagulant Therapy," by Professor H. W. Fullerton.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 3, 5 p.m., "Psoriasisiform Eruptions," by Dr. F. R. Bettley.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 3, (1) 11 a.m., "Neurosiphilis," by Dr. H. Nicol, (2) 5 p.m., "Injuries of the Kidney and Ureter," by Mr. A. W. Badenoch.

LONDON UNIVERSITY.—At London School of Economics and Political Science, Houghton Street, Aldwych, W.C., May 3, 5 p.m., "The National Health Service," by Sir James S. Ross (Ministry of Health).

LONDON UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, W.C., May 3, 5.15 p.m., "Physiological Properties of Ethyl Alcohol," by Dr. M. Grace Eggleston.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—May 3, 5 p.m., "Malaria with Special Reference to Recent Experimental Clinical and Chemotherapeutic Investigations," Croonian Lecture by Dr. N. Hamilton-Fairley, F.R.S.

WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY, St. Mary's Hospital Medical School, Paddington, W.—May 3, 5 p.m., "Surface Properties of Bacteria," by Professor E. W. Rideal, F.R.S.

Wednesday

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 4, 8 p.m., "European Vacation," by Professor W. J. B. Riddell.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 4, (1) 11 a.m., "Syphilis of the Skeletal System," by Dr. W. N. Mascall; (2) 5 p.m., "Hydronephrosis," by Mr. H. P. Winsbury-White.

LONDON COUNTY MEDICAL SOCIETY.—At Bethnal Green Hospital, London, E., in conjunction with St. Leonard's Hospital, May 4, 4 p.m., clinical meeting.

Thursday

EDINBURGH UNIVERSITY.—At Anatomy Theatre, University New Buildings, Teviot Place, May 5, 5 p.m., "Developments in the Surgery of the Labyrinth," Honyman Gillespie Lecture by Dr. A. Brownlie Smith.

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., May 5, "Homoeopathy and General Practice," by Dr. O. E. Manasse.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 5, 5 p.m., "Physio- and Electro-therapy," by Dr. R. T. Brain.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 5, 5.15 p.m., "The Surgical Treatment of Otosclerosis," by Dr. I. Simson Hall.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 5, (1) 11 a.m., "Syphilis in Pregnancy," by Dr. W. N. Mascall; (2) 5 p.m., "Anaesthesia in Urology," by Dr. T. A. B. Harris.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—May 5, 5 p.m., "Malaria, with Special Reference to Recent Experimental Clinical and Chemotherapeutic Investigations," Croonian Lecture by Dr. N. Hamilton Fairley, F.R.S.

ROYAL PHOTOGRAPHIC SOCIETY MEDICAL GROUP, 16, Prince's Gate, London, S.W.—May 5, 7 p.m., "The Future of Medical Photography," by Dr. R. G. W. Ollerenshaw.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—May 5, 4.30 p.m., "Neurology," lecture-demonstration by Dr. D. J. Williams.

Saturday

BRITISH MEDICAL SOCIETY.—At Department of Biochemistry, University Museum, Oxford, May 7, 1 p.m., 276th meeting.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—May 7, 11.30 a.m., "The Rehabilitation of the Deaf," by S. R. Silverman, Ph.D.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Archibald.—On April 11 1949 at 119, Moss Road, Northwich, to May, wife of Dr. R. McL. Archibald a daughter.

Davis.—On April 6 1949 in London, to Renate (née Loeser), M.B., B.S., wife of A. Davis F.R.C.S. a son.

MARRIAGE

Stillel—Baxter.—On April 16 1949, at Dunfermline Abbey, Dunfermline, Scotland, George P. Stillel, M.A., L.R.C.P.S. Ed., D.T.M. & H. Ed., Major R.A.M.C. and Miss Dorcas Baxter, M.B., Ch.B. Ed.

DEATHS

Barker.—On April 20, 1949, Chesman Barker, M.B., of Fair Haven, 9, Pevensey Road, Worthing aged 80.

Bone.—On April 14, 1949 at the Luton and Dunstable Hospital, John Wardle Bone, LL.D., M.B., Ch.B. Ed. of Rookwood, Luton, aged 79.

Currie.—On April 13, 1949 at 40, Inverleith Place, Edinburgh, John Ronald Currie, M.D., LL.D., D.P.H., F.R.C.P. Ed., Emeritus Professor of Public Health, University of Glasgow.

Correction.—Relying on a press report which we now know to be inaccurate, we erred in recording in our issue of April 16 (p. 688) the death of Dr. William Thomas Baker. In hastening to correct the error we very much regret any distress that this may have caused Dr. and Mrs. W. T. Baker.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vitamin D and the Skin

Q.—Is it possible to say how much ergosterol is present in the skin, and how much vitamin D is produced after exposure to natural or artificial ultra-violet light? Does the ergosterol in the skin play any major part in contributing to vitamin-D metabolism?

A.—Only traces of ergosterol occur in the skin. It forms about 0.5% of skin sterols, the most important of which are cholesterol and 7-dehydrocholesterol. It is the latter, and not ergosterol, which provides the vitamin D produced by irradiation of the skin—that is, vitamin D₂. It is not possible to say how much vitamin D is produced by exposure of the skin sterols to natural or artificial ultra-violet light, because the amount formed depends, among other things, on the quantity of sebum secreted, the time of exposure, and the concentration of the light rays. It is known, however, that rickets can be both prevented and cured by exposing the skin to ultra-violet irradiation without vitamin D being taken by mouth. Vitamin D appears to be formed by irradiation on the surface of the skin rather than in it, because if the sebum is removed from the skin surface little or no vitamin D is formed.

"Bat" Ears

Q.—What are the latest views on the treatment of "jumbo" ears (winged pinna)? What operation is performed, and is it wise to correct one ear at a time?

A.—"Jumbo" ears presumably means what are more commonly called "bat" ears. These should be reduced and set back in the proper position by means of careful excision of the ear cartilage and of the skin posteriorly. Both ears are done at once. The operation is far from easy and is best undertaken by an experienced plastic surgeon. The difficulty is, of course, to get the ears evenly placed; even more troublesome is the question of reducing each one in size, for they are usually hypertrophied.

Feeding Difficulties in a Small Child

Q.—What is the best treatment for a child with persistent anorexia? I have in mind a girl aged 4 whose two brothers are at boarding-school, so that for most of the time she is virtually an only child. She shows very little interest in food. She is active and has a lively imagination, but because she is thin and does not gain weight her parents are naturally anxious. They avoid pushing food into her because this results only in vomiting or regurgitation, and they feel that there is a danger of inducing a permanent dislike of certain foods, as happened in the case of one of the parents. The child does not ask for food between meals, and eats few sweets. The standard textbook advice to offer food, and to remove it unconcernedly and without comment if not eaten, appears to be a counsel of perfection, for if this is done she would have no meals. At children's parties the example of other children leaves her unmoved.

A.—It is misleading to consider the symptom of anorexia in isolation. As in adult life worry leads to loss of appetite and digestive disturbances, so in childhood any persistent lack of emotional ease is likely to be reflected in feeding difficulties. Factors affecting a child of 4 lie almost certainly in the home background, and especially in the mother-child relationship. It is significant not only that the parents are anxious about the child's lack of appetite but that this anxiety about food in one parent goes back to childhood and is now reflected upon this youngest child and only girl. It is highly probable that from early infancy parental over-anxiety about feeding has sensitized her to go off her food whenever she is herself anxious. In the absence of her brothers it may be that too much emotional

response is demanded from her, her activity may be the hyperactivity commonly reactive to such a demand. Remedies should be directed to reducing the parents' disturbance by every means possible, and to ending the "only child" position by the companionship of other children in a nursery school or similar group, preferably one where meals are provided. At home the routine of meals should be changed to provide novelty of setting, time, and food, and the "Do-eat-to-please-Mummy" attitude strictly avoided. If these measures are tried without success a child-psychiatrist should be consulted.

Blood-pressure Readings at Altitude

Q.—How does elevation above sea-level influence the readings of a sphygmomanometer of the Baumanometer type? Is there any formula by which the readings could be reduced to sea-level values in a locality at a considerably higher altitude?

A.—The only effect of altitude on the readings of mercury sphygmomanometers is that due to the decrease in the value of gravity with altitude. At altitudes up to about 10,000 ft (3,000 m) this effect is negligible in comparison with the accuracy obtainable from ordinary sphygmomanometers; instruments of the aneroid type are unaffected by this change in gravity.

It is useful to keep in mind the distinction between "blood pressure" and "the absolute pressure of the blood." "Blood pressure" as recorded by a sphygmomanometer is the amount by which the "absolute pressure of the blood" exceeds the ambient atmospheric pressure. Since atmospheric pressure varies with altitude, roughly by 25 mm of mercury per 1,000 ft. (300 m), and also changes from day to day, it follows that the "absolute blood pressure" may vary considerably although the observed "blood pressure" may remain constant. This statement is based on the assumption that the pressure on the sphygmomanometer—that is, the pressure in the sleeve applied to the patient—does represent the "absolute pressure of the blood."

Parity and Uterine Cancer

Q.—Is cancer of the uterus more common in women who have borne many children than in women who have had few or no children?

A.—Married women are more likely to die from cancer of the uterus than single women, but it is not possible, from official statistics, to determine whether the risk increases with the number of children the women have borne, since data are not available. The following compares the death rates per million among single and married women.

Age Group	1911-20		1930-2	
	Single Women	Married Widowed or Divorced	Single Women	Married Widowed or Divorced
15-19	14	49	12	39
20-24	89	259	85	215
25-29	296	628	220	473
30-34	537	864	405	654
35-39	608	932	522	817
40-44	709	811	626	856

The improvement during this period in the married women's mortality cannot be attributed to the declining birth rate, since the mortality of single women improved, relatively, at the same rate as that for married women.

Concretion Obstructing Milk Duct

Q.—A healthy woman aged 29 had been lactating normally for five months, when a swelling developed in the upper and outer part of the left breast due apparently to distension of one of the lobules. It was relieved after about 24 hours by expressing from the nipple a shiny white rubbery concretion 3 mm in diameter, during massage of the nipple this object got out, and was followed by a profuse discharge of milk from the affected duct. The obstruction occurred almost daily for the next two months affecting always the same duct. On some days as many as a dozen concretions would be expressed. At no time did infection arise although the engorgement was often prolonged and painful. The duct has now given no trouble for

several weeks. Lactation was normal after a previous pregnancy. What are the pathology and significance of the condition?

A.—The condition described is clearly one of milk engorgement of a lobule of the breast secondary to an obstruction of the main duct. The unusual features about the case are, first, the development of the trouble so late in lactation (it usually occurs in the earlier weeks) and, secondly, the character of the obstructing agent. The commonest causes of obstruction to a breast duct are either inspissated milk or a keratin plug at the skin orifice. White rubbery concretions must be an exceedingly rare cause of duct obstruction. The presumption is that they were derived either from inspissated milk or from a keratin plug. In view of the fact that the duct has now given no trouble for several weeks, and of the normal lactation after the previous pregnancy, it would be reasonable to hope that a subsequent lactation would be normal.

Sterilizing Syringes for Procaine Penicillin

Q.—The instructions for giving procaine penicillin specify the need for a dry sterile syringe and needle. How could this best be obtained under busy general-practice conditions?

A.—The only preparation of procaine penicillin should not be mixed with water, which may dissolve out some of the penicillin; a dry syringe is therefore recommended for injection. For the general practitioner the syringe may be sterilized by boiling in the evening and after assembly placed in a sterile glass tube of such a diameter that the flange of the syringe rests on the top of the tube. The syringe is then secured by a piece of adhesive cellulose or Scotch tape. Needles are similarly sterilized and can be left in small sterilized plugged test tubes with the mount resting on the bottom of the tube. During the day the syringe, provided it is used only for injections of penicillin, need not be re-sterilized, but a fresh sterile needle must be used for each injection. For further advice about the sterilization of syringes the Medical Research Council Memorandum No. 15, issued by HMSO (price 4d), may be consulted.

Proctalga Fugax

Q.—Could you give me the latest information on the aetiology, course, prognosis, and treatment of proctalga fugax?

A.—By proctalga fugax is meant a pain, located in the rectum, occurring in attacks which last from a few minutes to an hour and often make their appearance at night. The symptom is without organic basis, and, because it commonly attacks middle-aged tired, overworked, and over-anxious men, many doctors are among its victims. It has been described as a "visceral neurosis," but the pain must arise in some neuromuscular disturbance in the rectal wall, because many sufferers have found that distension of the rectum relieves it instantly. The symptom will often recur during periods of anxiety or emotional stress. General measures aimed at control of the factors noted are the basis of treatment. It is important to maintain a regular bowel habit. Sedatives may ensure an undisturbed night in minor cases; many sufferers are forced to use some local means of relieving the pain, such as distension of the rectum with air or saline by a Higginson's syringe. Sometimes a glycerin suppository is effective.

Indications for Thyroidectomy

Q.—Is thyroidectomy ever called for in the absence of symptoms of thyrotoxicosis? A married woman aged 41, not yet at the menopause, has for two years had a moderate degree of enlargement of both lobes of the thyroid. No cysts are present in the substance of the gland which is soft and uniform in texture. There are no signs of thyrotoxicosis but it has been suggested that a hemithyroidectomy should be performed. Is this advisable?

A.—This patient would seem to have what in old terminology was called a small parenchymatous goitre. As its consistence is uniform, and there are no pressure signs and no evidence of toxicity, it would seem that the only possible grounds (and these are slender) for advising operation would be appearance. Even in this case a hemithyroidectomy would certainly not

produce the required result. Such a goitre as that described in a patient aged 41 obviously needs to be kept under observation, but in the absence of signs and symptoms no operative treatment would appear to be indicated at present.

Terpenes as Industrial Hazards

Q.—I am medical adviser to a chemical factory producing insecticides. It is proposed to subject pinene, terpene, and camphene to chlorination by exposure to chlorine gas, and I have been consulted about the potential danger of absorption through the skin to workers or customers. The product would be used as an insecticide spray. I would be glad of any information.

A.—The substances named are constituents or derivatives of turpentine oils, and consist of the essential or volatile oils of numerous plants. Camphene, a colourless crystalline terpene, is prepared from pinene hydrochloride by treating with alcoholic potash. The irritant action of terpenes on the skin is well known. Chlorinated camphene is highly effective against the codling moth and Mexican bean beetle and also against human body lice. In the latter case, human research subjects wore arm and leg coverings which had been treated with chlorinated camphene in concentrations of 0.0025% in an inert base, and under which lice were also placed. All the lice were killed, but apparently no damage was suffered by the human volunteers with this low concentration. No toxicological study has as yet been published regarding the effects of chlorinated terpenes on the human subject, though their insecticidal effect is well established. There may be a toxic risk in the manufacture and handling of the concentrated material, and it would be wise to exercise precautions until experiment has shown that there is no danger, especially since highly chlorinated phenols, diphenyl, and naphthalene are known to have certain toxic properties. For the effects of chlorinated camphene on insect pests the recent papers by Stearns and others (*J. econ. Ent.*, 1947, 40, and 1948, 41) should be consulted.

Infertility

Q.—What is the explanation of the following case of infertility? The husband's post-coital urethral smear shows normal active spermatozoa. In the wife's vaginal-vault specimen one hour after coitus all spermatozoa are dead and show swollen heads. There is no leucorrhoea, and the hysterosalpingogram is normal.

A.—The important factor is the condition of the spermatozoa after they have invaded the cervical mucus plug. Provided the test is made at about the time of ovulation, the cervical mucus should be well populated by active spermatozoa for many hours following coitus. If spermatozoa are few or immobile, the failure may be caused by factors in the cervical mucus, but is more likely to be due to initial seminal deficiencies. It is not possible to judge seminal efficiency merely by finding active spermatozoa: their quantity, longevity, mobility, and the proportion of abnormal sperms are the diagnostic features. The inquirer might refer to *Problems of Fertility in General Practice*, by Margaret Jackson *et al.* (1948, Cassell).

Tonic Effect of Neoarsphenamine

Q.—Has neoarsphenamine any virilizing effect or does it act as a tonic when given to a healthy individual?

A. The writer knows of no evidence that neoarsphenamine increases virility, but it is a common observation that it has a marked tonic effect on patients suffering from syphilis. Whether this is due to a direct effect of the drug on the patient or to its antisyphilitic therapeutic effect is not clear, since the drug is rarely used, except in comparatively low dosage, in conditions other than syphilis.

Oxyuriasis

Q.—Would suppositories of gentian violet be efficacious in the treatment of oxyuriasis? My impression is that none of the regular treatments in this country is specific.

A.—In cases of infection with *Enterobius vermicularis* several members of the same family are usually infected, this communal infection being maintained by the ingestion of infective eggs, both by direct transfer from hand to mouth and by scatter

in dust. The larval worms, together with the adults of both sexes, occur in the small intestine, but the females, when gravid, make their way to the rectum and from there pass through the anus to lay their eggs on the perianal skin, a proportion of the "spent" worms regaining the rectum. Treatment with suppositories containing gentian violet would thus affect directly only the gravid females in the rectum and not those higher up in the colon. Though gentian violet may be absorbed by the rectal mucosa and excreted in the gall-bladder, as is suggested by the destruction of liver flukes after oral administration, it seems unlikely that a high concentration in the gut would be attained.

NOTES AND COMMENTS

Leukoplakia and Kraurosis Vulvae.—Mr. STANLEY WAY (Newcastle-upon-Tyne) writes: Dr. Elizabeth Hunt (March 5, p. 422) attempts to defend her untenable thesis concerning the value of excision of the leukoplakic vulval skin as a prophylaxis against cancer, and again repeats her erroneous claim that when cancer occurs in association with leukoplakia only the mucous surfaces are involved with tumour, and she calls to her aid two rather ancient references. Even though Blair Bell states that cancer has never been observed in extragenital lesions, I hardly think that this supports Dr. Hunt's thesis, for I do not think that Blair Bell would include the skin of the labium majus as extragenital; in fact in the earlier editions of his textbook (1910 and 1917) he states (p. 411 in both editions) that leukoplakia is pre-malignant and may spread from the vulva to the skin of the neighbouring structures. Dr. Hunt has not correctly followed the statement I made concerning my recent personal experiences. Indeed, on reading again my letter I feel that some ambiguity may arise from my wording, and I would like to repeat my figures more simply: total cases, 20; tumours involving mucous surface only, 2; tumours involving both surfaces, 6; tumours involving skin surfaces only, 12.

Because Dr. Hunt has never seen cancer associated with leukoplakia arising on the skin of the vulva, that does not appear to me a valid reason for her to adopt an ostrich-like attitude and deny its existence. Since writing my first letter I have operated on two further patients who showed small cancers limited to the outer surface of the labium, both of which were associated with leukoplakia. Dr. Hunt hopes that few people will have undergone what she describes as the "ordeal" of Taussig. She will no doubt be horrified to learn that I regularly carry out this operation, not only as a prophylactic against cancer but also to relieve women from the intolerable symptoms of leukoplakia; and I shall continue to do it until some effective alternative as a cure for leukoplakia is forthcoming. As a gynaecologist, I often see these women after the dermatologist has failed to cure them, and the only "ordeal" which many of the patients go through is that of going from dermatologist to dermatologist, from ointment to ointment, and from x-ray tube to x-ray tube, until in the end they either go mad or develop cancer. Finally, I would suggest that Dr. Hunt joins with me in persuading the Sections of Pathology, Dermatology, and Gynaecology of the Royal Society of Medicine to set up a committee to thrash out this vexed problem of terminology which is causing so much confusion at the present moment.

Family Planning Association.—The general secretary states that the address of the Family Planning Association's Seminological Centre is now 64, Sloane Street, London, S.W.1. Extension of the facilities previously provided (for the investigation and treatment of male subfertility) will include a laboratory for the diagnosis of early pregnancy. The results of the pregnancy test will normally be available within 24 hours of receipt of the specimen of urine. Practitioners wanting to avail themselves of these services or to refer patients are invited to write to the director of the laboratories at the above address. Introductory forms for patients will be sent on request.

Correction.—In the paper entitled "Medical Fitness for Air Travel," by Sir Harold Whittingham, Dr. A. Buchanan Barbour, and Wing Commander J. C. Macgown (April 9, p. 603), the words "into each site" should be deleted from the sentence, "Pneumo-peritoneal refill cases should not have more than 2,000 ml. of air introduced into each site." The same words should be deleted from column 2 of the Table at the cross-heading "Pneumoperitoneum" (11, viii).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Mediacea, Western, London.* B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 30 1949

THE SECRETARY REPORTS

LETTER FROM A DIVISION CHAIRMAN

The chairman of a Division with a fine record of service to the Association has felt impelled to send a personal letter to the members of his Division. It is of more than local interest, and is reproduced here in full.

Dear Sir,

There was a meeting of the Division of the B.M.A. last Sunday out of a possible attendance of 157, exactly 19 practitioners attended. There was no apology. As you received an agenda paper there is no need for me to emphasize the importance of the meeting.

"Naturally the paucity of the attendance caused comment, and four explanations were proffered. First, that the men in the Division were so satisfied with the conditions of service that no change was expedient, or, secondly, that doctors were so overwhelmed with work that they could not possibly spare the time to attend even so important a meeting as this. Both these suggestions were received with derision. The third explanation, that the Division placed such confidence in its executive that even a formal assent to the policy advocated would be supererogatory, though flattering to the officers concerned, was rejected by them as contrary to every known trait of the medical profession.

"The fourth explanation, and the most reasonable, was that a condition of complete and profound apathy pervaded the bulk of the doctors.

"After forty four years' service to my colleagues in the B.M.A. I feel that I am entitled to a little plain speaking. The Association is essentially democratic. All its actions are governed by the whole body of medical practitioners expressed at Divisional meetings throughout the country. Each Division elects its officers and appoints a representative, who is charged with the duty of expressing the will of the Division at the meeting of representatives. This meeting considers an agenda consisting of resolutions emanating from the Council of the B.M.A. together with amendments and further resolutions sent up by individual Divisions. The Council's resolutions are matters referred to it by a previous Representative Meeting and matters which arise between such meetings. The Council is self-elected and has power to institute the most complete investigation in all matters in its purview, calling in expert and professional advice wherever this is indicated as necessary. The amount of work done by the Council is literally enormous and involves a heavy rain on its members, whose services are entirely unpaid. This important fact—the full and complete analysis and scrutiny of any matter put before it—is not infrequently overlooked by Divisions which light-heartedly burden the agenda paper with resolutions which little knowledge of the facts would have shown to be foolishly vague. There is no excuse for this, because full data are published in the *Journal*, and any member who has failed to grasp the full implication of a resolution can always seek enlightenment from one of the Divisional officers at the meeting.

"Don't imagine for a moment that even a Divisional officership is sinecure. Far from it, and I speak, as I have said, with over forty years' experience. The work is often tedious and exacting and frequently thankless.

"Now, are you doing your share? Are you assisting in the task of putting State medicine on a proper basis or are you just letting time slide? The very least you can do is only as some mark of appreciation for the unpaid work of your fellow doctors on your behalf, is to turn up to the meetings and take an intelligent interest in the matters under discussion. Make every possible effort to attend. I know that sometimes—but not really often—this is impossible. In such case, let the honorary secretary—please note the word honorary—know so that I may absolve you of apathy.

"We are frequently asked to test the feeling of general practitioners in our Division on important matters of policy. How can we do

this if we have to report that 8% of our members approved unanimously, 92% did not turn up to the meeting and their wishes are accordingly unknown?

Please think this over. We shall inevitably have important meetings ahead. Do your bit.

Yours sincerely,
Chairman,
Division B.M.A.

Payment for Treatment of Miscarriages

In its determination to secure satisfactory terms and conditions of service the General Medical Services Committee continues to press upon the Ministry a number of points which have emerged during the early months of the new Service. For example, it was reported in these columns in January that the committee was contesting the Ministry's view that treatment for a miscarriage should be regarded as part of the ordinary obligations of a general practitioner under his terms of service. In order to meet the situation where a doctor is called in (otherwise than by a local health authority midwife) to deal with miscarriage in a woman with whom he has not made prior arrangements to provide maternity medical services (or to deal with some other Part I emergency in similar circumstances), the Ministry has agreed to allow form EC 24 or 24A to be completed afterwards so as to enable the doctor to claim payment of the Part I fee, provided that the miscarriage (or emergency) occurs after eight weeks from the beginning of pregnancy. Before that time any case requiring treatment would be dealt with as an emergency under ordinary general medical services.

If the doctor called in is not a general-practitioner obstetrician and not the patient's own N.H.S. practitioner (or his deputy) the former would hand over responsibility to the latter as soon as possible; the latter would claim the appropriate fee, to be divided up with his colleague by mutual agreement.

The Ministry has agreed that emergency confinements will qualify for Part II payments by the same procedure, provided that the woman had not booked with any other doctor and that the doctor was not called in by a local health authority midwife. If the doctor called in is not a general practitioner obstetrician and not the patient's own N.H.S. doctor (or his deputy), the position as regards claiming and apportioning the appropriate fee would be the same as that described for miscarriages.

Bulk Prescribing

The question of bulk prescribing for residential schools and institutions has also been under discussion. The Ministry's first reaction was that provision could be made for the prescription on a single form of drugs needed for a number of persons, the number to be specified by the practitioner. The G.M.S. Committee objected to the suggestion that the prescription should relate to a precise number of people. It argued that if there was to be economy in public funds from bulk prescribing the practitioner should be able to prescribe for the school or institution as a whole and should not be limited to the actual number of persons in respect of whom medicines, etc., are necessary. The Ministry has accepted this proposal in principle. It has not, however, agreed to the inclusion of dressings in the bulk arrangements; it expects that every home or institution would carry a small stock of equipment of this kind for its own purposes.

National Health Service

INCIDENCE OF SICKNESS

Some have thought that there has been a large increase in the number of persons consulting a doctor since the Health Service started last July. Among the suggestions for this rise are that it is partly due to an increase in the number of women and children seeking advice and partly because treatment is sought for minor ailments more frequently than before. The December issue of the quarterly return of the Registrar-General includes the Survey of Sickness for the September quarter of 1948. The experience of this quarter may be compared with that of the corresponding quarter of 1947. A slight rise in sickness has occurred among adults; the percentage of persons interviewed, aged 16 and over, who reported no sickness during the month was 31.0 for the three months in 1947 and 29.4 in 1948. The rise in sickness was reported by persons of working age and occurred in each of the three months. The distributions are as follows:

TABLE I.—Percentage of Persons Interviewed Who Had an Illness during the Month

	1947		1948	
	Ages 16-64	Ages 65+	Ages 16-64	Ages 65+
July	69.0	85.1	73.0	81.3
August	65.9	83.0	69.3	80.0
September	64.9	83.6	67.2	84.2
Average	66.6	83.8	68.7	81.8

The increase in incidence was accompanied by an increase in the number of medical consultations and by a rise in the proportion of sicknesses which incapacitated for one day or more, as Table II shows.

TABLE II.—Percentage of Illnesses among Persons Aged 16 and Over

	Medical Advice Sought		One or More Days of Incapacity	
	1947	1948	1947	1948
July	14.2	15.7	6.0	6.7
August	13.0	14.8	5.2	7.1
September	11.9	14.9	5.9	7.6
Average	13.0	15.1	5.7	7.1

The increase in medical consultations was due to the females, who showed an increase in each of the three months, while the males showed a decrease (Table III).

TABLE III.—Medical Consultations per 100 Persons Aged 16 and Over

	Females		Males	
	1947	1948	1947	1948
July	37.0	43.8	36.3	36.0
August	36.3	39.2	33.8	32.1
September	35.0	42.1	33.4	30.8
Average	36.1	41.8	34.5	33.0

An examination of the age distribution of the females (Table IV) shows that the increase in consultations was mainly due to the older women.

TABLE IV.—Percentage of Women Interviewed Who Consulted a Doctor during the Months July-September

Ages	1947	1948
16-	29.8	30.7
25-	29.5	30.4
35-	30.4	33.7
45-	37.7	46.6
55-	48.4	51.3
65-	41.1	55.7
75-	57.9	78.4
All ages	36.1	41.8

The Survey of Sickness shows that, compared with the corresponding quarter of the preceding year, an increase of about 4% has occurred in the numbers of adults seeking medical advice. This is a smaller increase than would be expected from individual doctors' reports, but no account has been taken of sickness among children, which may account for the difference. The increase has been due to the females, and the rise has been largest among the older women. This is not quite in accord with expectation, which was that a considerable part of the increase was due to women with families, mother and child both attending as patients more often now than in the past.

NUMBER OF PRESCRIPTIONS

The Ministry of Health has supplied the following information on the prescribing done by doctors in England only from July to Sept. 30, 1948.

	July 5-31	August	September (Partly Estimated)
No. of patients on doctors' prescribing lists	33,501,762	33,501,762	33,501,762
Total no. of prescriptions	10,059,903	11,088,781	12,668,408
	£693,123	Not available	Not available
	£525,771	Not available	Not available
	£104,743	£115,317	£131,746
Total prescription costs	£1,323,637	£1,471,386	£1,677,984
Average cost per prescription	31.578d.	31.844d.	31.789d.
Average no. of prescriptions per patient on doctors' prescribing lists	0.300	0.311	0.378

The Ministry adds that it has no exact figures for the number of patients on prescribing lists. It has taken the estimated number of people who decided to make use of the general medical services and assumed that 90% of them are on prescribing lists, 90% being approximately the percentage under N.H.I.

The figures show an average of one prescription for each patient on doctors' prescribing lists for the quarter ending Sept. 30, 1948.

HIGHLANDS AND ISLANDS

The Standing Advisory Committee on Health Services in the Highlands and Islands held its first meeting on April 8 and elected Councillor Donald Macpherson chairman and Dr. Isaac Maciver vice-chairman. (Members were listed in the *Supplement* of March 5, p. 123.) The committee is to advise the Secretary of State on problems in the Highlands and Islands. It will meet next at Inverness on May 14.

N.O.T.B. ASSOCIATION

The N.O.T.B. Association, representing 594 ophthalmic medical practitioners and dispensing opticians, held its first General Meeting on April 1. A resolution was unanimously passed by the medical members urging a fuller representation of the part-time ophthalmic medical practitioner, and ophthalmic medical practitioners solely concerned in the Supplementary Ophthalmic Service, on the Ophthalmic Group Committee of the B.M.A. and the Ophthalmic Negotiating Committee.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar

Non-County Borough Councils.—Dartford, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

GENERAL MEDICAL SERVICES COMMITTEE

ARBITRATION AND SPENS

At a meeting of the General Medical Services Committee held on April 21 at B.M.A. House the chairman, Dr. S. Wand, gave a report of the unsatisfactory meeting which the committee's representatives had had with officials of the Ministry on the remuneration of general practitioners, and referred to a statement from the Ministry that "it must not be assumed without further discussion that participation in the Whitley machinery necessarily involves, in the event of disagreement, the right to resort compulsorily to arbitration on all subjects."

Before the committee considered the business of the meeting members stood in silence for one minute in tribute to the late Dr. Bone, and a message of sympathy has been sent on its behalf to Dr. Bone's relatives.

The committee also received with regret the resignation owing to pressure of other work of Dr. J. Hallam, and expressed appreciation of his assistance on this and the Insurance Acts Committee.

Giving his report of the meeting with representatives of the Ministry of Health on April 14, at which the committee's representatives presented a memorandum on the inadequacy of the central pool and its distribution, the chairman said that it was very unsatisfactory. The Ministry did not discuss the document at all. Despite the statements made in the House of Commons, the Ministry said it was unable to state precisely how many doctors were in the Service. It was asking executive councils for information on this and the total remuneration received by general practitioners from National Health Service funds, and they anticipated that this information would be available about the middle of May. Until the Ministry had this information it could not state whether Spens was being applied, and it could give no assurance that any adjustment which might be made would be retrospective to the appointed day.

After referring to the Ministry's statement that Whitley machinery did not, in all circumstances, carry the right to arbitration, Dr. Wand pointed out that the profession had always understood that on matters of remuneration arbitration could be claimed. Dr. Dain (Chairman of Council) indicated that, had they known it was not, a different decision might have been made about joining the Service.

The Ministry estimated that about £49.41 million was being received by general practitioners, a sum which included inducement money, additional mileage, superannuation, and other remuneration, such as maternity fees, grants for trainee assistants, etc.

The Chairman of Council, who was also a member of the deputation to the Ministry, agreed that the interview was "very unsatisfactory." The Ministry was obviously aiming to meet the profession's claims by the suggestion that it was already implementing Spens, and it would not agree to any adjustment or discussions until its present inquiry had been completed.

"We must wait until the Government knows the numbers in the Service," continued Dr. Dain. Then it would be for the committee to decide whether Spens was in fact being implemented. If it was not they should ask for the matter to be put to arbitration; there the Association could develop the argument for the betterment factor in public. Whitley machinery or no Whitley machinery, they should ask for arbitration. The Ministry had stated that it must not be assumed, without further discussion, that Whitley machinery necessarily involved the right to resort compulsorily to arbitration "on all subjects." "But," remarked Dr. Dain, "we never asked for arbitration on all subjects, but on remuneration it was essential."

Dr. W. Jope thought a firm stand should be taken against the Ministry's attitude that whether they had been underpaid or not the 1948-9 period was finished and they would get no more money for it.

Dr. H. H. D. Sutherland felt the ground for a probable dispute with the Government should be prepared at once. The view that the profession should be taken into confidence

and work done on public relations was also expressed by Dr. F. M. Rose.

Dr. J. A. Brown recalled that at an earlier meeting at the Ministry the Minister had been asked whether remuneration was an appropriate matter to bring before a Whitley Council, and Mr. Bevan replied: "Yes." "His promise did not seem to have any strings to it," said Dr. Brown, "and he should be held to it."

Summing up, the chairman remarked that the Ministry could have given the profession what it asked, or given a smaller sum, or nothing at all. In fact, the Ministry gave nothing at all—and raised the crucial issue of arbitration. "Although the discussions with the Ministry had been unsatisfactory," said Dr. Wand, "I think the Ministry has underestimated the feeling of the profession on arbitration. On this question we have got the consultants, the public health people, and the nurses with us."

The committee then passed the following resolution, to be sent to the Ministry of Health, local medical committees, and (for their information) to the Public Health Committee and Consultants and Specialists Committee:

The committee records its dissatisfaction with the Ministry's inability to state, nine months after the appointed day, the number of principals taking part in the Service, and the statement that, in so far as the pool may prove to have been inadequate for the first nine months of the Service, any increase may not be adjusted retrospectively to the appointed day.

In view of the statements made by responsible Ministers prior to the appointed day, the committee is of opinion that the Ministry's view that disputes concerning remuneration referred through Whitley machinery do not carry the right of arbitration on either side is a gross breach of faith.

In considering the Executive Subcommittee's report, the committee passed a resolution expressing concern at the delay in bringing forward the amending Bill.

The subcommittee considered it was "not in the interest of private practice that facilities for seeing private patients should be available at health centres." A number of members of the committee, however, pressed for the right of private patients to be seen at health centres if they and their doctor wished it and subject to any safeguards that they should not receive preferential treatment. The matter was referred back. Dr. A. T. Rogers also raised the question of what might happen if a doctor gave up a lock-up surgery to go into a health centre and the local executive council allowed another doctor to take over his premises. This was referred to the executive subcommittee.

The subcommittee's attention had been drawn to a letter issued by a regional liaison officer of the Ministry of Health stating that the executive council could, under certain circumstances, acquire compulsorily an outgoing doctor's premises. Legal advice is being sought to find whether councils have in fact this power.

On the question of certificates for corsets, it was explained that a certificate was still needed if the garment was made with certain materials. It was agreed to take the matter up.

Dr. A. T. Rogers presented the minutes of the Subcommittee on the Training of Assistants, of which he was chairman. The subcommittee reported that the Ministry's scheme was primarily for the benefit of the trainee and should be regarded as such. Any financial benefit which the principal might hope to derive from the help given by the assistant could and should be met in other ways. The present scheme should be reviewed within 12 months of its commencement.

The report of the Rural Practitioners Subcommittee was given by its chairman, Dr. J. C. Pearce. The subcommittee considered that areas with geographical difficulties should be given extra payment for mileage. The committee agreed with a recommendation from the subcommittee that a practitioner practising in an area where a mileage scheme normally operates, whether he is on the obstetric list or not, should be entitled to a single payment for each maternity case booked, at the rate of 2s. per mile (outward) over two miles from the practitioner's residence to the patient's address, such payment being a first charge on the Central Mileage Fund. The subcommittee thought that, having regard to the alternative open to doctors

of being paid for dispensing on the drug tariff, no action should be taken on a motion from Hexham at the Special Representative Meeting in March calling for an increase in the dispensing allowance. The Ministry of Health has agreed to claims for special payment where the cost of dispensing for a patient is abnormally high, the minimum now to be 20s. a quarter instead of 10s. under National Health Insurance. The committee is asking that the 10s. minimum be retained.

The minutes of the Scottish Subcommittee were received. One resolution called for priority treatment under the Supplementary Ophthalmic Service; this is to be discussed with the Department of Health.

A letter from the Ministry referring to the treatment of foreign visitors under the National Health Service declared that there was "no question of change of view or of a Government Department 'making or breaking the law.'" In discussion members complained that people on extended visits abroad were being taken off their doctor's lists, although their absence was only temporary.

A resolution from the Private Practice Committee asked the committee to consider a War Office suggestion that officers and men who fell sick on leave should be treated as "temporary residents." The committee favoured adhering to existing arrangements.

The committee received with concern the decision of the Ophthalmic Group Committee not to take any action in the matter of provision for an appeal against the decision of the Ophthalmic Qualifications Committee, and asked the Group to reconsider their view and allow members of the General Medical Services Committee to discuss the matter with them.

The chairman described as "not satisfactory" a refusal by the Board of Inland Revenue to make any general arrangements for the collection of tax from doctors by quarterly instalments, but said if any doctor had difficulty in paying owing to reduced earnings he could discuss the matter with the Inspector of Taxes, and any local refusal would be taken up centrally by the Association on the basis of the letter. The Chancellor had declined to recognize that conditions under the National Health Service were comparable to those in the war. The committee asked for evidence of specific cases of financial difficulties, on which the Association could ask the Ministry of Health to advise the Chancellor to alter his attitude.

Arising out of a motion passed at the last Annual Conference which the committee had sent to the Central Consultants and Specialists Committee for their observations, the committee decided that a practitioner should be able to engage a consultant for domiciliary consultation either through an official channel or directly, as he wished.

It was announced that the Central Consultants and Specialists and Public Health Committees agree to the setting up of a joint subcommittee with the General Medical Services Committee on the report of the Working Party on Midwives.

National Insurance Defence Trust

As Trustees of the National Insurance Defence Trust, the Committee voted £500 to start the funds of the British Medical Guild. Dr. W. D. Steel felt it might be better to choose the executives of Divisions as local executives of the Guild. The chairman explained, however, that the view had been expressed that the Guild should not have the same constitution as the Association all the way through; some doctors in an area who were not members of the Association might not regard the executive of Divisions as the proper "task force" to raise subscriptions from all medical men and women. The committee postponed further consideration of the Guild until its next meeting.

It was agreed that under the new Trust Deed a simple majority of the trustees (that is, the members of the General Medical Services Committee) should be sufficient to vote sums up to £1,000, and that for sums over £1,000 a quorum of 50% and a majority of two-thirds of those present and voting should be necessary. Further legal advice is to be obtained before the present arrangements are formally wound up and the new Trust established. The chairman suggested that in the future the Trust should continue to raise funds from general practitioners and vote sums to the Guild as desired.

PRIVATE PRACTICE COMMITTEE

The Private Practice Committee met at B.M.A. House on April 20, with Dr. I. D. Grant in the chair.

A number of items on the agenda concerned increased fees for medical examinations. Communications from the Ministries of Labour and National Service, Pensions, and National Insurance contained proposals for mileage payments of 1s. per mile, with a maximum of 20s., for any one journey for doctors attending panels and boards. In view of the urgency, these proposals had been accepted by the chairman on behalf of the committee and took effect from March 17.

The Admiralty has agreed to pay 25s. for the medical examination of candidates for Civil Service appointments.

Territorial Army

There was some discussion about medical examination of recruits for the Territorial Army. The chairman said the War Office agreed that where possible these examinations should be carried out by medical boards, and arrangements would be made to use the boards administered by the Ministry of Labour and National Service. In exceptional circumstances, however, such as in rural areas, it might be necessary for the examination to be made by a single practitioner. The committee agreed that it was most desirable that the Pulheims examination should be carried out by a board wherever practicable. The Association had suggested £1 11s. 6d. as the fee for such an examination; the War Office doubted whether the Treasury would sanction more than £1 1s., as the fee had already been raised to 10s. 6d. The committee agreed to give further consideration to this question when the reply of the War Office was received. The Chairman of Council (Dr. H. Guy Dain) explained that any proposal received regarding fees would go first to the Co-ordination Committee for their examination.

The committee again considered the medical report required by licensing authorities in the case of applicants to drive public service vehicles. A letter from the Ministry of Transport stated: "I believe the Association and the Ministry are at one in desiring a uniform and reasonably low fee . . ." for such a report, and asked for suggestions. The committee agreed that, as the fee for this report would ordinarily be paid by the applicant and was therefore a matter between doctor and patient, no recommendation as to fee should be made.

The committee considered that the fee for a "certificate of health" required for prospective employees of a certain county council—a matter raised by the Yorkshire Branch—ought to be paid by the employing authority.

A reply from the Treasury stated that the purpose of the new Treasury Health Service would be to advise Departments, regarding the health of individual officers and on environment and working conditions in relation to the health of the staff, and to provide emergency attention in cases of accident or sudden illness occurring on Government premises. The committee agreed to a scale of fees for local Treasury medical officers.

Criminal Justice Act

It was reported that practitioners had been asked to make examinations of prisoners under Section 26 of the Criminal Justice Act, 1948, for a fee of £1 1s. and that appropriate action had been taken to inform these practitioners that in the view of the Association the fee for this service should be £2 2s. In reply to a question the view was expressed that when a local medical committee was asked to help in forming panels for work of this or any other kind the fairest way was for them to circularize all general practitioners, who could then apply or not, as they wished.

A letter from the National Deposit Friendly Society stated that, despite the National Health Service, the Society wished to continue to pay grants in aid to its members in respect of private doctor's bills. The committee approved the Society's proposals in principle and decided to recommend that doctors who did not do their own dispensing should make arrangements with the chemist regarding the supply of medicines.

so that the patient might receive an inclusive account. The patient would pay the doctor and receive from the Society the grant-in-aid to which he or she was entitled.

It was agreed that, when a statement of the future policy of the National Coal Board with regard to the terms of service of part-time colliery medical officers had been obtained, a conference of part-time colliery medical officers should be called to discuss the method and rates of remuneration. This had been recommended by a joint subcommittee of the Private Practice and Occupational Health Committees. It was revealed that there is at the moment much variation of practice in different divisions of the board.

Further discussion took place on the recommendation that a distinctive motor badge should not be made available to members of the Association, but the committee saw no reason for changing its views. The chairman thought they had fulfilled the remit from the Representative Meeting, for they had had a badge designed, which could be available for inspection at the meeting at Harrogate.

Questions Answered

Study Leave

Q.—Employed in a National Health Service hospital, I am training to become a specialist. Am I entitled to any time off work (in addition to my annual vacation) in order to sit an examination (a) in my chosen specialty, and (b) in general medicine—i.e., for a higher medical qualification?

*A.—*The proposed terms and conditions of service of hospital medical and dental staff (*Supplement*, March 19) contain provisional proposals for "study" leave. Professional examinations are included in the purposes for which such leave may be granted. Study leave additional to annual leave cannot be claimed as a right but may be granted for periods up to seven days

(1) without pay or expenses, at the discretion of the board of governors or hospital management committee;

(2) with pay, but with or without expenses, at the discretion of the board of governors or regional hospital board, subject to certain qualifications regarding the payment of expenses. Authority to grant leave with pay but without expenses may be delegated to the hospital management committee.

For periods between seven days and three months study leave may be granted with or without pay and expenses at the discretion of the regional hospital board or board of governors, again subject to the conditions regarding the payment of expenses. Periods of study leave in excess of three weeks involve the surrender of a proportionate amount of annual leave. Periods of study leave with pay in excess of three months may be granted only with the sanction of the Ministry of Health.

Dental Anaesthetics in Hospital

Q.—I recently administered an anaesthetic for a dental case in a hospital. The dentist, under his contract with the hospital, is entitled to a fee of 2 guineas plus mileage, as the case was an emergency to which he was summoned by the hospital. I am informed that as I hold no specialist appointment for anaesthetics my remuneration is covered by the £25 per bed staff fund. Dental anaesthetics in the dentist's surgery are regarded as outside the terms of service and are the subject of special payment. I submit that dental anaesthetics in the hospital should likewise be subject to special payment. Am I correct?

*A.—*A general practitioner appointed to the staff of a cottage hospital is required to attend his own patients in the hospital, sharing with the other members of the staff any attendance on the patients of practitioners not on the staff and taking the appropriate share in any necessary emergency in-patient or out-patient work. In order to provide remuneration for this work the hospital management committee creates a staff fund by making a payment of £25 per annum for each bed occupied on the average in the hospital, and the fund is shared between the general-practitioner staff as they may themselves determine.

An anaesthetic rendered for a dental emergency would be regarded as part of the normal in-patient work undertaken by the general practitioner for which he is remunerated out of this staff fund.

Compensation

Q.—I have received the compensation value of my practice under Section 36 of the National Health Service Act, but not the number of years purchase payable to me. Will the increased number of doctors serving lessen the compensation originally calculated at 1½ years? If so, is it known by how much?

*A.—*It is impossible for the time being to determine the rate, expressed as years' purchase, applicable to individual assessments. The factor to be applied to the annual loss cannot be ascertained until the aggregate of all claims is known. The increased number of doctors serving does not necessarily affect the calculations, since compensation is payable only to those who were on the list of executive councils on July 5, 1948.

Prescribing Syringes

Q.—What are the arrangements under the N.H.S. for the repair of broken glass barrels of hypodermic syringes prescribed for diabetic patients for the self-administration of insulin?

*A.—*The patient's practitioner may prescribe another syringe on Form E.C.10.

HEARD AT HEADQUARTERS

A General Practitioner in Natal

The Science Committee, which decides on the award of the Association prizes, found itself confronted with a little difficulty over the Sir Charles Hastings prize this year. The prize is supposed to be awarded for general practitioner work, but lately hospital records have been rather prominent in the essays submitted. An outstanding essay was submitted this year on a series of operations; it was a remarkable record of 2,844 operations carried out over a number of years by a general practitioner in Natal. They had been performed many miles from his home, some of them in fairly large hospitals, but more than half in small hospitals or in the patient's home or in a hut. In view of the resourcefulness and skill displayed by a general practitioner the adjudicators had no hesitation in considering it worthy of the prize which bears the name of the founder of the Association. The prizewinner is Dr. C. E. L. Burman, of Pietermaritzburg, a graduate of Durham University.

The "Medresco" Hearing-aid

A correspondent recently stated (*Supplement*, March 19, p. 157) that the Government-sponsored Medresco hearing-aid is being sold abroad, but the Ministry of Health denies this: it is available only through the National Health Service. At present there are insufficient to meet the large demand quickly, but considerably more are expected to be available shortly.

Reluctant Patients

There are indications that the National Health Service is causing some illness to be missed—illness that did receive medical attention before. In the old days, if people wanted a doctor they sent for him and paid him for his services and so felt themselves under no obligation. Now a lot of people are reluctant to send for the doctor early in illness for fear of imposing on him, for whatever may be said about abuses of the Service many people are like that. When the child wakes up ill in the morning, the mother, anxious not to trouble the doctor, waits in the hope that as the day goes on the trouble will disappear, and eventually very often has to send for the doctor at night. One busy urban practitioner told us that during the first six weeks of the new Service there were only two evenings on which he was not called out to see such cases. He has now made it known among his patients that if there is illness in the morning, even if it seems to be of only a temporary character, he would rather be called in at once so that he could see the case on his rounds than be called at a late stage when the illness had become worse.

Correspondence

Status of Specialists

SIR,—I have noted with some surprise that so far no one has made any comment on the current trend of events in official circles with regard to hospital specialists and their classification and salary scales. I am well aware that the Iron Curtain is still the order of the day so far as the policy-makers of the N.H.S. are concerned, but the pattern for the immediate future is emerging with increasing clarity, even though it may not be displayed in its unsavoury entirety.

Wide publicity has been given in the general press to the proposed salary scales for hospital specialists, which are sufficiently generous to meet with uniform approval; but the public has not been informed of the stringent and arbitrary limitations which are being contemplated on the number of individuals who are to be officially recognized as specialists. It has already been stated—in an unobtrusive amendment to the first announcement—that the category of senior hospital officer may include whole-time members of hospital staffs employed in specialized duties, and it is becoming abundantly clear that the Minister intends to relegate the maximum number possible to this status. This implies that on completion of the specified term as a trainee specialist one is automatically "graded" as a senior hospital officer, in which category one may continue indefinitely unless a vacancy "on the establishment" occurs. In this way, by the time the age of 40 is reached the Government is saving £1,000 per annum.

In the proposed terms of remuneration no definition is made of a specialist. This is a much too convenient omission, which I suggest should be rectified, and I would offer this as a possible definition: "A specialist is one who is wholly employed in a particular branch of medical science in which he has, over a period of years, acquired experience and training of a scientific and technical nature which is not catered for in the ordinary course of undergraduate training."

It is utterly indefensible to suggest that any individual should, on the completion of a prolonged apprenticeship in a recognized specialty, be then placed on the same footing as other members of the profession who have not undergone such training. The Government recognizes the existence of specialized duties, but if, as it would appear, it proposes to pay specialists' salaries only to a minute percentage of the staff who perform these duties, then the B.M.A. is under an immediate obligation to make it clear that this cannot be tolerated.

It has been obvious of course that, having committed itself to the allocation of merit awards to a fixed percentage of specialists, the Government would take steps to ensure that its financial liabilities in this respect should be kept to the barest minimum. However, when the steps envisaged amount to compelling the vast majority of the members of specialized departments in the N.H.S. to give their services without recognizing their right to be paid accordingly, the strongest possible action is called for—I am, etc.

G. G. W.

D. M. McCCLURE.

Pay of Service Medical Officers

SIR—The B.M.A. Council's proposed increased scale of remuneration for medical officers of the armed Forces (para 151 of the Annual Report of Council, *Supplement*, April 2) will be received with little enthusiasm by most serving officers. The proposals, so apologetically summarized in the last paragraph of the memorandum, confirm the prophecies of the sceptical and are unlikely greatly to change present dissatisfaction. They suggest rather a lack of real appreciation by the Council of the true feelings of many serving officers. As a medical officer serving in the armed Forces has so few opportunities of expressing his views on his own remuneration, perhaps you will permit me to record a few facts as I see them as a regular officer neither very junior nor very senior.

There exists to-day widespread dissatisfaction among serving officers both at conditions of service and in particular at remuneration. While the former is largely reluctantly accepted

as an unavoidable consequence of special post-war circumstances shared by all Service personnel, the latter has been pointedly brought to a head by the publication recently of the Government's proposed scale for full-time specialists in the National Health Service.

The Council now proposes that all regular Service officers should be classified as the equivalent of average general practitioners for purposes of remuneration. This I most strongly challenge. However accurately it may reflect the opinion of the civilian profession on Service doctors as a whole, it is far removed from fact. The regular Service doctor of to-day, by the time he reaches field rank or its equivalent, is a specialist if ever there was one, in no way inferior professionally to his civilian counterpart in the National Health Service. In most cases, with the completion of the 18 months' postgraduate studies (to take the Army for example) which follow his selection for a permanent commission, he becomes a recognized full specialist with a higher qualification, Service or civilian. As often as not he has already been a graded specialist for some years previously. In the remainder of cases he has chosen medical administration, itself a skilled special branch of medicine which must receive official recognition as such. As one who has had some experience both as an administrator and as a specialist, I would have little hesitation in putting the former among the most exacting and important of all special branches of medicine. In brief, the Service doctor, after the age of, say, 35, rightly considers himself to be in every way the equivalent of the full-time specialist in the National Health Service, and he expects, differing merely in the Government Department in which he is employed, to be remunerated at a strictly equivalent scale. His case for this is unassailable.

Voluntary recruitment to the medical branches of the armed Services is unsatisfactory. There have been resignations since the war, including some very able and experienced officers whose loss the Services can ill afford. Other resignations have not been accepted, because of the continued existence of the "emergency." In nearly all cases the real reason has been financial. These facts are well known to the Defence Ministry. What is perhaps not so well known is that there are at present many more officers "sitting on the fence" waiting to see what is going to happen about their pay. They are profoundly disturbed by the financial situation in which they have found themselves since the war. Their pay at home is so inadequate, with their many commitments, as to make living, even with greatly restricted standards, extremely difficult without running into debt. Service abroad has for various reasons, one of which is the enthusiastic abandonment of a large part of the Empire, lost much of its pre-war attractions. Now it usually means just more separation from one's family and extra expense. They feel they did not become doctors for this.

Loyalty to the Service is all very well, but one has other loyalties, in particular to one's family. Can, therefore, the specialist regular doctor be blamed if he quietly waits for a suitable job to turn up under the National Health Scheme and then puts in his papers? As things are at present it is not a question of if, but when. He will get congenial work in his specialty; with luck he will double his pay; he will have a permanent home with no more family separation; his superannuation will compensate for the loss or reduction of his pension; and, finally, he may rest assured, from experience during the last war, that his recall in another emergency will involve him in loss of neither status nor promotion. This is what most Service medical officers are shirking at present. This is why they are contemplating resignation. This is why recruitment is poor and will remain so. Refusal to accept resignations, except under special circumstances, is no cure for it. The emergency cannot last for ever. Meanwhile it merely strengthens doubts as to the wisdom of accepting a permanent commission.

There can be but one cure for this. That is for the senior Service doctor to receive exactly equivalent remuneration to his civilian specialist counterpart in the National Health Service. Nothing shows if this will attract the type of officer required or even retain many serving specialists who, still young enough to be ambitious and with little wish for compulsory retirement while still in their professional prime, now know of another Government service in which they can obtain employment with remuneration appropriate to their professional skill and qualifications. Until this is done, the armed Forces will attract only the very wealthy (!), the adventurous bachelor, or the failure elsewhere. The proposal of a scale already rejected by G.P.s as inadequate may perhaps attract young graduate doctors to a temporary short-service commission, but it leaves the more senior officer cold. And this from the B.M.A., which has made such a principle of equity within the profession!

There must be a uniform scale for all doctors of equivalent status who are paid by the Treasury whether in the armed Forces or the Health Service. Let this be Principle I. Although the G.P. equivalent

is appropriate for more junior officers below substantive field rank, thereafter all Service officers must be accorded full specialist status for which they are fully qualified. Only officers suitable for this should be selected for permanent commission. Let this be Principle II. Subsequent promotion, being by selection, represents a well-earned rise in professional status and should carry a Special Distinction Element as in the Health Service (accepting that medical administration is itself a specialist branch of medicine). Let this be Principle III. This would give a Director-General the full £5,200 (adjusted as necessary for pension and betterment) which his position certainly demands. Substantive majors, etc., the equivalent of full specialists, would receive £2,000-£2,500 according to service, and more senior ranks appropriate increases corresponding, with suitable modifications, to the Special Distinction Awards of the N.H.S. The distinction between general duty and specialist officers would cease to exist once substantive field rank had been reached. Below field rank the rates proposed are not unsatisfactory.

This represents quite a rise. The Treasury will not like it (but with little justification, as they have already accepted it for N.H.S. specialists), and claims for rises in other arms will no doubt follow. These facts, however, interest neither the serving officer contemplating resignation nor the potential regular volunteer looking for a suitable specialist career. And they in the long run are the only ones who really matter.

It is what must come eventually, and it is a pity that B.M.A. leadership, which is all the serving officer has, has only been able to take us half-way.—I am, etc.,

Marriage Allowances for Medical Officers

SIR,—The Secretary of the Association stated in a footnote to my letter (*Supplement*, Jan. 1, p. 8), referring to the marriage allowance of National Service officers, that the matter was not decided. May I point out that this is no longer so, and that the Minister has now attempted to clarify this point?

Although the increased scale of allowances was alleged to offset the high cost of living, the Minister states that they cannot apply to National Service medical officers who are apparently too young to incur any increased costs of living. To quote his own words in the House of Commons on March 23, 1949: "If at this very young age men were married, knowing the basis of the allowances, then they came into the Services knowing what they were doing." It would be easy to argue with this bizarre statement in many ways, but I would like to draw attention to one point.

Prior to this recent increase full marriage allowances were payable to all officers over the age of 25 years, regardless of rank or type of engagement. A doctor joins the Service as an officer and has an officer's expenses during his Service engagement, whether that engagement lasts 1½ or 4½ years. No difference in these expenses exists other than that they may fall rather more heavily upon the man with the shorter term of service, and yet this makes a difference of 6s. per day to the Service doctor.

A medical officer's responsibilities and duties, within his own rank, are in no way minimized by the fact that he is on national service. He is, in fact, not comparable with the 18-year-old National Serviceman who enters the Service from school or apprenticeship—i.e., completely untrained and unqualified for any immediate useful service. This, I feel, makes the Minister's ruling appear both unfair and false.

Finally, I can see medical officers on national service looking longingly to the Association's proposed increases in pay, which might ease their penury. I humbly suggest that they purge their minds of such adventitious thoughts, as these increases will apply only to the regular or semi-regular minority and not the National Service majority of medical officers.—I am, etc.,

London, N.3.

E. J. TRIMMER.

* At a recent meeting the Armed Forces Committee considered the fact that National Service officers are not entitled to the recently announced increases in marriage allowances in the Forces, and the fact that their leave entitlement is substantially less than that of regular and short-service officers. This discrimination reacts especially hardly upon medical officers, many of whom, because of the relatively late age at which they do their national service, are married before entering the Forces. A recommendation on the subject has been forwarded to the Council.—Ed. B.M.J.

Graduated Capitation Fee

SIR,—I cannot believe that Dr. J. W. O. Holmes (*Supplement*, March 26, p. 164) really means what he implies, for he has made a gratuitous insult to about 90% of the G.P.s. So anybody who does not run a large N.H.I. list is either lazy or incompetent! Is that really so? The doctor with a very large list will always give reasons, flattering to himself, why he has a large list—viz., he is a good doctor, he is a hard worker, he has a pleasing personality, patients like him; he has, in fact, all the virtues. It might also occur to him that the possession of a large list may be really due to chance. Before the N.H.S. came into being the commonest way of getting a large practice was to buy one. To-day the only way is to walk into one, and what a chance! Conditions now are static, and, since all patients are equal from the remuneration aspect, those doctors with medium- or small-sized lists have little hope of increasing their practices however hard they are prepared to work and however excellent they may be as clinicians. Those who are practising in "over-doctored" areas and have suffered a sharp fall in income might like to transfer to "under-doctored" areas. Just let them try and see what happens!

In pre-war days owners of swarming panel practices were hardly considered to be the élite of the profession, and with good reason. What does Dr. Holmes mean by being able to manage 5,000 with ease? As Dr. Joad might say, it all depends on what is meant by "manage." If general practice is to consist in writing certificates and Forms E.C.10 and making spot diagnoses, then it should be possible to "manage" even 10,000 patients, in which case the profession is grossly overmanned; and yet we are told that there are not enough doctors to run the N.H.S. properly.

No doubt the owners of large lists will protest that they deal adequately with every patient, but I would never believe them. Owing to the very nature of their practices they are bound to deteriorate as doctors, using the title "doctor" in the truly professional sense.

Viewpoints such as those of Dr. Holmes are irritating and depressing, as they show the difficulty of getting all G.P.s to organize and work together for better conditions, and incidentally for a better National Health Service. A few more such jettlers and some people may start thinking about the advantages of a salaried service. A doctor can only work well when he is free from financial anxieties and able to give full attention to a reasonable number of patients, since there are only twenty-four hours in the day. These are the two things we strive for, and we are not asking for the moon. I see that the specialists have obtained these conditions, neatly and quietly. "Managing" a list of four to five thousand is not medical practice.—I am, etc.,

London, N.12.

A. J. ROUSE.

A Form of Absenteeism

SIR,—I am in no way connected with the National Health Service, and perhaps for that very reason am impressed by the difficulties of a colleague who joined the Service some months ago. I asked him how he was liking it, and he said his life was a series of explosions which brought his wife to him with cups of strong coffee and words of comfort. He gave me the latest example, which he said was typical.

An apparently healthy young woman presented herself and demanded an iron tonic. He refrained from the obvious remark—that she had come to the wrong place—and spent some ten minutes or so in unravelling her symptoms, when the fact was revealed that she had a young man in the Merchant Navy who was away on a voyage and she was feeling his absence. My friend suggested that a mild sedative might be more helpful, but she persisted in her demand for an iron tonic, which he then refused her.

Then she asked for a certificate for a new body-belt. He spent a further ten minutes in examining her, and, finding no trace of visceroptosis or hernia or even undue adiposity, said that he did not feel justified in prescribing a belt for her. Whereupon she expressed herself dissatisfied with the interview and demanded her card.

By trying to administer this Service in a fair and intelligent manner, as it is intended to be administered, and by acting as a

responsible individual instead of a dog's body, my friend wastes 20 minutes and loses a patient. At the same time the patient's new doctor will gain another capitation fee without expending more than two minutes on the transaction.

What a system! What a magnificent encouragement to the upholding of professional integrity! What a noble career for an aspiring student!

Can nothing be done to encourage my friend and those like him? Can nothing be done to penalize a man who is content to distribute the taxpayer's money in a reckless, slipshod manner without even troubling to examine his patients? My friend receives letters from his headquarters asking him to explain his reasons for declining to prescribe (he showed me such a letter). Surely he might be saved this additional burden on his time by the investigation of complaints by a medical umpire or umpires, and if it were found that the doctor's refusal was reasonable he could be reimbursed for the time and trouble he had taken in preventing an abuse and in saving the taxpayer's money.—I am, etc.,

London, S.W.7.

J. N. LORING.

Telephone Costs

SIR,—Does the Minister intend to reimburse us with the increased costs of telephones in view of the fact that the Chancellor states that the increases on the budget are necessitated by the cost of the social services? Unless my arithmetic is more than usually wrong I can only assume that in paying an increased charge to the P.M.G. I am really paying a contribution towards my own income. If this is so, then equity has been made subservient to law, whereas it is a maxim laid down over centuries that "where equity and law are in conflict equity shall prevail."—I am, etc.,

Carbis Bay, Cornwall

L. P. LOCKHART.

The B.M.A. War Memorial

SIR—At a recent meeting of the Harrow Division held on April 5, 1949, paragraph 6 of the Annual Report of Council (*Supplement*, April 2, p. 174) was discussed at length, and I have been asked to express the views of the meeting.

It is fitting that an organization such as the B.M.A. should express its appreciation of those who have served and given their lives in the second world war, and the monetary sum of £10,000 is but a token of that appreciation, but that this sum should be spent on a fountain is a most inadequate expression of our feelings. By all means let us record the names of those who served on a Roll of Honour to be kept at B.M.A. House, but let us do something far more active and tangible for the dependants of the fallen. One suggestion would be to use the fund for scholarships to educate the dependants.

Whatever may be the eventual use to which we put the money it is essential that a much fuller and more widely published discussion should first take place, and for this purpose it is desirable that the Council should refer the matter to the next Annual General Meeting of the Association before proceeding further.—I am etc

J. S. LINDSAY.
Hon Sec. Harrow Division

Domiciliary Midwifery Payments

SIR—The payment of the G.P. with regard to domiciliary midwifery is anomalous, there being no comparison between the N.H.S. fees and the emergency fees payable through the Midwives Medical and Emergency Summons.

Under the N.H.S. scheme a fee of 7 guineas is payable for every booked case, and although this is a very low fee it does in fact average fairly satisfactorily if the doctor is only called to a proportion of these cases.

The position with regard to the Midwives Medical Aid request is in a totally different category. The doctor is only paid for the actual case that he attends—invariably a complicated one or he would not have been summoned—yet the maximum fee that he can claim to cover every attendance to the mother and child during the confinement and puerperium is 4½ guineas. Either this fee should be increased to bring it into line with present-day values or the doctor should be paid a retaining fee for every case booked by a midwife.—I am, etc.,

London, S.W.16

HARRIS AVERY.

Senior Hospital Officers

SIR,—I was amazed to find in a medical journal this week an advertisement for a specialist stating that the officer appointed would hold the rank or grade of senior hospital officer. I was under the impression that the Minister's proposals based on the Spens Committee Report (I could find no basis in this report for the insertion of this grade in these proposals) was under discussion by the profession and that no action would be taken until negotiations had taken place and agreement had been reached.

At two meetings which I have attended recently the specialists present unanimously condemned this grading, expressed an opinion that it was contrary to the spirit of the Spens Report, and stated that it was unnecessary and undesirable. I hope, Sir, that you will not accept any advertisement in your *Journal* for such posts, and I hope that all young specialists will refrain from replying to such advertisements. It is quite obvious that, alarmed at the annual bill for the Health Service (the cost of which was so grossly underestimated by the experts), the administrative side are trying to "pull a fast one" on the specialist side of the profession. Many of us have seen capable young men in the Forces working as graded specialists with a junior rank and lower pay than their merits deserved. Surely these young men will take warning from their wartime experience and will refuse to go into the blind alley of senior hospital officer appointment.—I am, etc.,

MENS SANA.

* * The Secretary of the Association states: Pending the completion of negotiations with the Government on the permanent scales, no advertisements inviting applications for specialist posts, the successful applicant to be graded as a senior hospital officer, will be accepted for publication in the *British Medical Journal*.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—At Boscombe Hospital, Friday, April 29, 8.15 p.m., Address by Dr. T. Sommerville, of the Research Unit (National Institute for Medical Research), Harvard Hospital, Salisbury: "Common Cold."

EAST SUFFOLK DIVISION.—At Lecture Theatre, Pathology Department, East Suffolk an... Friday, April 29, 8.15 p.m., Lecture by Surgeon... Milne, R.N.: "Pain in the Fore-part of the..." by lantern slides.

GOOLE AND SELBY DIVISION.—At The Lodge, Snaith, Sunday, May 1, 3.30 p.m., annual meeting.

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Thursday, May 5, 8.30 p.m.: Agenda: (1) Address by Dr. N. Lloyd-Rusby: "Some Recent Advances in the..." and Treatment of Diseases of the Chest"; (2) Report on... Meeting of March 29 and 30; (3) Instructions to Representatives to Annual Representative Meeting, etc.

LEWISHAM DIVISION.—At Lewisham Hospital, 390, High Street, London, S.E., Friday, May 6, 8.30 p.m. Annual general meeting.

NORTH MIDDLESEX DIVISION.—At Prince of Wales's Hospital, Tottenham, N., Wednesday, May 4, 8.45 p.m., annual general meeting.

OXFORD DIVISION.—At School of Geography, Mansfield Road, Oxford, Wednesday, May 4, 8.15 p.m., combined meeting of Oxford, Reading, and Buckinghamshire Divisions. Agenda: Address by Dr. Charles Hill, etc.

RICHMOND DIVISION.—At Royal Hospital, Richmond, Tuesday, May 3, 9 p.m. Annual meeting.

WESTMINSTER AND HOLBORN DIVISION.—At Holborn Town Hall, High Holborn, London, W.C., Thursday, May 5, 8 p.m., annual meeting.

WIGAN DIVISION.—At Hindley, Wednesday, May 4, 2 p.m., golf competition open to all members of the medical profession in Wigan and district. Entrance fee 5s.

PATHOGENESIS OF ESSENTIAL HYPERTENSION*

BY

F. H. SMIRK, M.D., Ch.B., F.R.C.P., F.R.A.C.P.

Professor of Medicine University of Otago, New Zealand

The purpose of this paper is to present in a preliminary way some suggestions in regard to the pathogenesis of essential hypertension. An introductory historical review of the subject is omitted, as several reviews are available already.

1. Evidence that Physiological Elevation of Blood Pressure Predisposes to Essential Hypertension in Later Life

Even when the blood pressures lie within limits regarded as normal, individuals whose pressures are higher than the average have a higher-than-average incidence of hypertension and circulatory disorder in later life, whereas those whose pressures are below the average have a decidedly lower-than-average incidence of essential hypertension and of circulatory disorders in later life (Symonds, 1923; Association of Life Insurance Medical Directors and the Actuarial Society of America, 1925; Diehl and Hesdorffer, 1933; Trans Internat Congress Life Ass Med, 1935; Actuarial Society of America, 1939; Robinson and Brucer, 1939; Hunter, 1939; Hines, 1940; Actuarial Society of America, 1941).

Reference will now be made to some of the factors influencing the blood-pressure level. Especial attention will be given to the relationship of such factors to the expectation of the development of essential hypertension in later life.

Race and Geographical Environment

European and North American white people have somewhat higher average and modal casual blood pressures than certain Indian, Chinese, African, Philippine, and American Indian peoples, and the incidence of high blood pressure is decidedly lower among the latter group. The differences between the average blood pressures of such groups may be 10 to 20 mm systolic and 8 to 15 mm diastolic for comparable ages. While race seems to influence the liability to essential hypertension (Kirk, 1931; Shattuck, 1933; Flaxman, 1934; Kean, 1941), environment also has a strong influence, and this predisposition seems to be closely related to the levels of the blood pressures encountered in the populations under consideration.

For example, China appears to provide an environment favouring lower blood pressures and less essential hypertension. North America favours higher levels of the normal blood pressures and much essential hypertension. The blood pressure of Chinese in China is below that of Canadian and United States citizens resident in their own countries (Cadbury, 1922, 1923; Yine, 1926; Kilborn, 1926; Foster, 1927; Tung, 1928, 1930). Essential hypertension in much of China is also uncommon (Cadbury, 1922, 1923; Cruickshank, 1923; Kilborn, 1926; Foster, 1927, 1930) even among well fed sections of the community (Houston, 1929). Krakower (1933-4) states that the blood pressure of Chinese after long residence in Canada resembles that of other Canadian residents and that essential hypertension is common. Tung (1928) found that 30 Chinese resident in the United States had falls of pressure on returning to Peking. Tung (1927) reported that 58 Americans had a distinct fall of blood pressure on taking up residence in China, and Foster (1927) found that 120 Americans in Hunan had an average pressure close to that of the local Chinese.

African negroes have lower blood pressures than those of their race who live in America (Donnison, 1929) and the

incidence of high blood pressure is low among negroes in Africa (Heimann, Strachan, and Heyman, 1929; Shattuck, 1930; Schulze and Schwab, 1936). The latter authors also quote personal communications from Taylor, Odalev, Drv and Wakeford. American negroes after the age of 20 have higher blood pressures than American whites (Alvarez and Stanley, 1930; Adams, 1932), and the incidence of high blood pressure is greater in negroes than in white residents of the United States (Stone and Vanzant, 1927; Donnison, 1929; Alvarez and Stanley, 1930; Allen, 1931; Holmes, 1931; Kirk, 1931; Adams, 1932; Laws, 1932-3; Flaxman, 1934; Weiss and Prusmack, 1938; Hedley, 1941). Hypertension of a few days' duration after exposure to explosive blast was more common in negroes than whites (Ruskin, Beard and Schaffer, 1948). Hypertension is greater among town dwellers than among country dwellers of the same race and land (Holmes, 1931; Flaxman, 1934). East Africans also have lower blood pressures and less essential hypertension than North American or Western Europeans (Donnison, 1929; Williams, 1944a, 1944b). Egyptians on the whole have lower blood pressures than Anglo-Saxon peoples and a somewhat lower incidence of essential hypertension (Ismail, 1928; Smirk, unpublished observations). British residents in Egypt have slightly lower blood pressures than the average in Great Britain (Smirk, unpublished observations).

The blood pressure in Filipinos and in Porto Ricans is lower than in people of the United States (Concepcion and Bulatao, 1916; Ashford and Dowling, 1929; Torgerson, 1929; Salcedo and Pascual, 1932; Lantin, 1933) and hypertension is probably less frequent (Ashford and Dowling, 1929; Torgerson, 1929; Lantin, 1933).

Among the poorer classes in India blood pressures are lower (McCay, 1907) and essential hypertension is less common than in Anglo-Saxon lands (Raghavan, 1941).

The South American Indians of Yucatan have low blood pressures and a low incidence of essential hypertension (Shattuck, 1933). The Cuna Indians, living relatively isolated, had an average pressure of 105/69 for 407 adults, and no case of hypertension was discovered among them (Kean, 1944). The Zuni Indians have low blood pressures and little hypertension (Fleming, 1924).

Hicks (personal communication) found a systolic blood pressure of 110 was the most common in young Australian aboriginals, and in 120 aboriginals between 60 and 65 he found no blood pressures higher than 130 systolic. Benign hypertension is not uncommon in Australian Whites. Nye (1946) also remarks on the low incidence of hypertension in Australian aboriginals.

Certain environments favour higher "normal" blood pressures and other environments favour lower "normal" pressures. Populations exhibiting higher "normal" pressures have a higher incidence of essential hypertension and those with lower "normal" blood pressures have a lower incidence.

Hereditv

Hereditv influences the level of the blood pressure. According to Ayman (1936) the children of two hypertensives have higher blood pressures and a 47% chance of hypertension in later life. When both parents are hypertensive the blood pressures of the children are lower and the incidence of essential hypertension is only 3%. This is evident from observations on identical twins, though differences may sometimes lead to different blood pressures in identical twins. Additional evidence is cited by

*The subject matter of lectures delivered as visiting Professor of Medicine at the British Postgraduate Medical School, Harpersmith.

Obesity

Obesity is statistically associated with over-average blood-pressure levels (Dublin, Fisk, and Kopf, 1925; Huber, 1927; Hartman and Ghrist, 1929; Kirk, 1931; Nuzum and Elliot, 1931; Short and Johnson, 1939; Robinson, Brucer, and Mass, 1940; Adlersberg, Coler, and Laval, 1946). This relation is found not only in the common forms of obesity but also in the obesity of Cushing's syndrome and in cortical hyperadrenia. Under-average body weight is associated with under-average levels of the blood pressure (Symonds, 1923; Huber, 1927; Robinson, Brucer, and Mass, 1940). Over-average blood pressures in children of over-average weight is also reported (Stocks and Karn, 1924; Short and Johnson, 1939). Manifest essential hypertension is also more frequent in the obese (Symonds, 1923; Terry, 1923; Dublin, Fisk, and Kopf, 1925; Barach, 1928; Master and Oppenheimer, 1929; Gager, 1930; Kirk, 1931; Nuzum and Elliot, 1931; Palmer, 1931; Short and Johnson, 1939; Robinson, Brucer, and Mass, 1940; Rony, 1940; Moschowitz, 1945; Adlersberg, Coler, and Laval, 1946). Essential hypertension and obesity are to some extent genetically determined (Gates, 1946), although the relationship between them is scarcely understood (O'Hare, Walker, and Vickers, 1924; Page and Corcoran, 1945). Like twins exhibit very similar body weights (Rony, 1940), and their blood pressure is usually about the same level (Weitz, 1923; Hines, 1937-8; Klemola, 1938).

The relationship of obesity to hypertension, however, is not purely genetic, for loss and gain of weight from altered food intake are associated with fall and rise of blood pressure. This relationship between alteration in body weight and blood pressure has been observed in the obese and in persons of normal weight, in normotensives (Benedict, 1915; Benedict, Miles, Roth, and Smith, 1919; Preble, 1923; Bauman, 1928; Master and Oppenheimer, 1929; Moschowitz, 1945), and in hypertensives (Preble, 1923; Rose, 1923; Terry, 1923; Master and Oppenheimer, 1929; Moller, 1931; Moschowitz, 1945; Adlersberg, Coler, and Laval, 1946). In normal dogs and in hypertensive (Goldblatt, 1947) dogs, Wood and Cash (1939) showed that gains and losses of weight were associated with rises and falls of blood pressure. The effect of overweight on the blood pressure in man seems to be more pronounced after 40, corresponding to the age when the incidence of essential hypertension rises.

The blood-pressure fall corresponding to an average reduction of 24 lb. (10.4 kg.) was about 32 mm. systolic and 16 mm. diastolic in the 72% of obese hypertensives in the series of Adlersberg, Coler, and Laval (1946), who had a fall of blood pressure. The difference in the average blood pressure between more or less unselected groups of overweight and underweight individuals is about 10 mm. systolic and 8 mm. diastolic. The effect of obesity is more obvious, however, when the comparison is made between the percentage of hypertensives encountered in individuals who are over the normal standard weight as compared with the percentage among subjects who are under the normal standard weight.

It is clear that overweight is associated with a tendency to higher blood-pressure levels, and in the course of time a higher incidence of essential hypertension. Under-average weight is associated with lower blood pressures and decreased tendency to essential hypertension in later life. Errors in blood-pressure measurement by cuff methods and due to upper-arm obesity require further evaluation.

Transient Blood Pressure Increases

Of the blood pressure rises which occur in response to excitement most are transient, but many are of longer duration. Tivon Monakow, 1920; Fahrenheit, 1926; Weitz and Sieben, 1926; Grollman, 1929; Houston, 1929; Brown, 1929-30; Aidikan, 1930; Mueller and Brown, 1930; Stieglitz, 1930; Alcatrazfeld, 1932; Schultz, 1932; Ayman and Goldshine, 1940; Alam and Smirk, 1943a, 1943b; Ehrström, 1945). Emotional rises of pressure of 10 or 20 mm. are common, and rises of 40 mm. or more are encountered. Such transient pressure increases are exhibited particularly at the first visit in connexion with an examination for military

service, life assurance, student health survey, or clinical examination. That most of these transient rises are due to emotion, tenseness, alertness, or some such mental state is very highly probable, because nearly all subside, sometimes in a few minutes, if the subject can be put at ease (Weitz and Sieben, 1926; Mueller and Brown, 1930; Ayman and Pratt, 1931; Alam and Smirk, 1943a, 1943b; Smirk, 1944, 1947; Kilpatrick, 1948). The pressure often can be made to rise promptly again if emotion be provoked, for example, by a tactless remark or the entry of a nurse with a tray of instruments (Alam and Smirk, 1943a; Kilpatrick, 1948). Those who exhibit such transient blood-pressure elevations have a much greater chance of developing permanent arterial hypertension later (von Monakow, 1920; Frost, 1926; Palmer, 1930; Stieglitz, 1930; Robinson and Brucer, 1939; Hines, 1940). Even in young people transient rises carry an enhanced expectation of developing essential hypertension later (Palmer, 1930; Diehl and Hesdorffer, 1933; MacKenzie and Shepherd, 1937; Master, 1943; Rogers and Palmer, 1944; Levy, White, Stroud, and Hillman, 1945a, 1945b).

I am aware of no evidence which points to the existence of any pathological process in young subjects exhibiting transient hypertension and which might explain it. Transient blood-pressure elevations in otherwise healthy individuals under the age of 25 probably represent physiological responses of a magnitude greater than average. These might occur if vasomotor reactions or the mental reactions to physical stimuli or stress are excessive.

The reactions to vasomotor reflexes, such as the cold pressor test of Hines and Brown (1935), and the blood-pressure-raising reflex from voluntary muscle (Alam and Smirk, 1937) are usually greater in cases of essential hypertension than in healthy subjects of the same age group (Alam and Smirk, 1938). The elevations of blood pressure in response to psychical stimuli and in response to cold do not invariably show parallelism (Ruskin, Beard, and Schaffer, 1948). Hines and Brown (1935) state that the pressure-rises in response to cold are greater in the children of hypertensive parents than in those of normotensive parents. They consider that hyperreacting normotensives are more likely to develop hypertension in later life. Evidence in the same direction comes from Diekmann and Michel (1935). Evidence against the views of Hines and Brown has been published (Pickering and Kissin, 1936; Yates and Wood, 1936; Feldt and Wenstrand, 1942; Russek, 1943; Russek and Zohman, 1945). The matter is not yet settled.

Not all patients respond to nervousness or tenseness to blood-pressure rises (Hall, 1927), but those who do, and whose environment causes nervous tension, may be expected to exhibit those increases more often than normal individuals. Fischer (1930) states that mental exertion unaccompanied by emotion had no notable effect on the blood pressure, whereas Hill (1898), Bickel (1914), and Gillespie (1924) report that mental work elevates the blood pressure. Changes in the mental state of melancholic and other psychotic and psychoneurotic patients may be associated with considerable alterations in the blood pressure (Mueller, 1922). There are large individual differences in the reactions to mental stimuli, but many authors consider essential hypertensives are over-reactive, overtense physiological types (Moschowitz, 1919; Ayman, 1933; Menninger, 1938; Binger, 1945).

No doubt transient hypertension is due in many cases to a combination of vascular lability with emotional lability, but sometimes one or other of these will predominate. The more restless and competitive environment of urban as distinct from rural life has been held responsible in American negroes and whites for the higher incidence of essential hypertension in urban communities (Holmes, 1931; Hashimoto, Akatsuka, Tsujii, and Shiraishi, 1933-4; Schulze and Schwab, 1936). Stocks and Karn (1924) state that the average blood pressure of children is higher in schools with strict discipline than in those where discipline is lax. Tigerstedt (1926) refers to the higher blood pressures in students in the few weeks before an examination. Ruskin, Beard, and Schaffer (1948) report considerable hypertension of some days' duration in persons exposed to explosive blast. Fraser and Cowell (1918) refer to the higher level of the blood pressure in front-line troops.

when compared with supporting troops, and somewhat similar results have been reported by others (Gelshtein, 1943; Ehrström, 1945; and Graham, 1945). It has been claimed by Farris, Yeakel, and Medoff (1945) that repeated exposure of rats to an air blast may set up a lasting arterial hypertension. This has been confirmed by Restall and Smirk (unpublished observations), who have shown also that this hypertension is not abolished by anaesthesia.

The tendency to exhibit transient hypertension in response to mental and other stimuli may be taken to indicate a physiological make-up which is likely to express itself in daily life by abnormally strong and frequent blood-pressure elevations. The balance of evidence suggests that such elevations, if sufficiently frequent or prolonged, predispose the subjects towards the development later of essential hypertension.

2. Casual, Basal, and Supplemental Pressures

If the level of the blood pressure in health is an important indication of the future liability to essential hypertension, it will be important to know what significance should be attached to single or to multiple readings of the blood pressure.

The blood-pressure level in a ward or consulting-room is not an accurate guide to the average blood pressure of the patient throughout the day and during the night (Brooks and Carroll, 1912; Müller, 1921; MacWilliam, 1923; Campbell and Blankenhorn, 1925-6; Friedlander, 1927; Ayman, 1931; Master, 1943; Gubner, Silverstone, and Ungerleider, 1946). Were it possible to obtain some indication of the average of the pressures to which the vascular system was exposed a much closer correlation between this average pressure and the subsequent development of essential hypertension might be possible. It is, however, possible to discover the ranges over which the blood pressure is likely to fluctuate.

The blood pressure, even in health, is not to be regarded as an indivisible unity but as having two components. If the blood pressure (systolic and diastolic) taken under ordinary clinical conditions be considered as the casual blood pressure and that taken under defined basal conditions as the basal blood pressure, the difference between the casual and the basal blood pressure may be described as the supplemental pressure (Alam and Smirk, 1943a; Smirk, 1944). The supplemental blood pressure is, by definition, that part of the casual blood pressure which represents the response to the person's physical, metabolic, and cerebral activity at the time of measuring the pressure. Kilpatrick (1948) has confirmed and extended my observations on the basal blood pressure and has shown that in health the basal blood pressure is a physiological constant for the individual. In a series of 50 normal subjects (Smirk, 1944) the basal and supplemental pressures were independent variables in the sense that the possession by an individual of a high basal pressure neither increased nor appreciably diminished the expectation of that individual having a high supplemental pressure. Analysis of further experiments by Kilpatrick gives the same result. In a sense, therefore, among normals a person comes into the higher pressure range through the statistical coincidence of having both a high basal and a high supplemental pressure.

During undisturbed dreamless sleep the supplemental pressure falls to, or almost to, zero, whereas the basal pressure is substantially unaffected. The cardiovascular strain will be less if a given level of the casual blood pressure is derived from a low basal pressure and high supplemental pressure than if the reverse holds. Clinical experience (Alstad and Smirk, unpublished) suggests that high casual blood pressures due chiefly to a higher basal pressure are of more serious significance than casual blood pressures of equal height caused chiefly by an increase in

the supplemental pressure, but the latter may be associated with pathological sequelae of hypertension.

Further relevant observations on basal and supplemental pressures have been reported elsewhere (Alam and Smirk, 1943a, 1943b; Smirk, 1944, 1947; Kilpatrick, 1948). Statements are made that blood pressures over 135 in young adults are to be regarded as abnormal. It is suggested that the decision rests to some extent on our concept of abnormal. I believe some confusion would be avoided if the decision about the normality or abnormality of a blood-pressure level were held to depend upon whether it is attained through the normal operation of physiological processes or whether it is elevated to some extent by pathological processes. Moderate elevations of the blood pressure may at first be induced entirely by the operation of physiological processes. Some of these physiological processes are intrinsic and represent a physiological set or a resultant of the many intrinsic factors influencing blood pressure. Some factors influencing the blood pressure, such as geographical and social environment, are extrinsic, and others, such as obesity, are probably both intrinsic and extrinsic.

The hypothesis suggested by the circumstantial evidence outlined above is that physiological elevations of the blood pressure, if high enough or of sufficient duration, predispose strongly to, or in some cases cause, the development of a pathological elevation of the blood pressure—namely, essential hypertension. Those influences which lead to elevation of the basal pressure probably predispose more strongly to the subsequent development of essential hypertension than influences which elevate only the supplemental pressure.

3. Evidence that in Essential Hypertension Blood-pressure Elevation Sometimes Precedes the Development of Arteriosclerosis

The evidence comes partly from the many clinical reports of high-blood-pressure tendencies at an early age, when primary pathological changes in the vessels are unlikely (Glomset, 1931; Ayman, 1934; Hines, 1940; Kerley and Lorenze, 1942; Levy, Hillman, Stroud, and White, 1944; Graham, Hines, and Gage, 1945; Platt, 1948), and partly from histological and renal function studies. The temporary nature of the blood-pressure rises initially also suggests that an established humoral mechanism (e.g., Goldblatt) is not operating at this early stage.

Cases of essential hypertension in which the kidney taken at necropsy was normal have been reported by many authors (Pal, 1919; Bell and Clawson, 1928; Moritz and Oldt, 1937; Fishberg, 1939; Garretton-Silva, Rodríguez, and Aspillaga, 1941), although most of them regarded this as an exceptional finding. When, however, cases are selected deliberately from patients in the early stages of the disorder, normal kidneys or those showing minimal changes are often encountered (von Monakow, 1920; Wallgren, 1922). Thus kidney samples from early cases, removed at biopsy in the course of sympathectomy operations by Castleman and Smithwick (1943), have shown few of the findings characteristic of the more advanced cases encountered at necropsy.

Scott (1944) and Goldblatt (1947) criticized Smithwick (1944), in that his biopsy samples were too small. Smithwick's histological observations, however, are supported by the finding of almost normal diodrast excretion, which corresponds with results published by Page and Corcoran (1945). My histological observations on post-mortem material from moderate hypertensives under the age of 40, and dying of unrelated disorders, suggest that recognizable defects in arterioles may be lacking. Where

arteriolar changes were found they were much less in degree than those exhibited by the arterioles of elderly normotensives.

Cox and Dock (1941) perfused the kidneys of patients with essential hypertension and of controls and found the flow through the kidneys decreased with age, the decrease being but little greater with essential hypertension kidneys than with control kidneys from the same age group. Kimmelstiel (1933), perfusing kidneys, found little vascular obstruction in many early cases of benign hypertension, with equal or greater vascular obstruction in some elderly normotensives. McGeorge (1945) demonstrated a decrement in the renal function with increasing age, and pointed out that the renal function of young hypertensives was similar to that of young normotensives and both exhibited a better capacity to concentrate urea and chloride simultaneously (Smirk, 1933-4, 1934) than either old normotensives or old hypertensives. The decrease in renal function progresses more rapidly in cases of essential hypertension than in non-hypertensive controls. It seems very probable that the decrements in renal function with advancing years in normotensives and in essential hypertensives are due largely to decrease with age in the blood supply to the kidneys, with a more rapid decrease in the latter. Aitken in his unpublished work for a New Zealand M.D. thesis in 1944 undertook at my suggestion some observations on injected specimens of kidneys from young subjects of essential hypertension and also found the vascular beds to be substantially normal.

Indeed, it would seem that the evidence of gross pathology, microscopical pathology, intra-arterial injection studies of kidneys, biopsy studies of kidneys, perfusion of dead kidneys, renal function tests of various kinds, and the intermittent character of the blood-pressure increase in its early stages all suggest that the degree of permanent renal ischaemia in the early stages of essential hypertension in young subjects is unimportant and is not to be regarded as an adequate explanation of the blood pressure increases. *The evidence available at the present time suggests that when the disorder starts or when a "prehypertensive" state is present in comparatively young people the elevation of the blood pressure is often, probably usually, manifest before the characteristic pathological changes make their appearance in the kidney and in other organs.*

In many patients, however, the blood pressure does not start to rise appreciably until after the age of 40 or 50. When the blood pressure first rises after the age of 45 pathological changes in renal arterioles of one kind or another will almost certainly be present before the blood-pressure increase has reached the level ordinarily regarded as abnormal. It is possible, therefore, that in at least some of the cases in which the blood pressure begins to rise appreciably for the first time in middle life the renal ischaemia may have initiated the increase.

4. Evidence that High Blood Pressure Accelerates or Causes the Development of Arteriosclerosis

In almost every muscular organ an increase in work beyond the physiological range of any kind of muscle—cardiac, voluntary, or involuntary—leads to hypertrophy. The cardiac hypertrophy in hypertension and the development of voluntary muscles with physical labour are well known. In the alimentary, urinary, and biliary tracts partial obstruction leads to hypertrophy of the muscle behind the obstruction. In the larger vessels of well-established cases of essential hypertension hypertrophy of the media is encountered. Vascular hypertrophy is seen in small pulmonary arteries obstructed by the bilharzia ova (Shaw and Ghareeb, 1938).

The walls of veins hypertrophy when exposed to raised pressure in arteriovenous aneurysm, the portal veins in cirrhosis of the liver, and the great systemic veins in congestive heart failure (Pei-Lin Li, 1940). In high blood pressure of varying types, essential hypertension, glomerulonephritis, pyelonephritis, polycystic kidneys, medullary hyperadrenia, cortical hyperadrenia, and in experimental hypertension of different types the typical thickening in the walls of arterioles has been described. Such changes may occur even in young children with hypertension of various origins. It seems that this hypertrophy also is due to the effect of increased pressure on the walls of blood vessels. Although the vast majority of observations strongly favour the idea that high blood pressure can cause hypertrophy of the walls of arterioles and of larger arteries a certain amount of evidence is either opposed to or fails to support this idea. In coarctation of the aorta it is stated (Graybiel Allen, and White, 1935) that the arterioles in muscle samples taken in the upper part of the body showed no hypertrophy when compared with muscles taken from the lower part of the body. On the other hand, arteriolar hypertrophy in coarctation cases has been reported (Heyer and Keeton 1941).

Again, there are a number of instances in the literature of high blood pressure of appreciable duration with few changes in the arterioles. In experimental hypertension in animals of various types arteriolar changes are sometimes found and sometimes lacking (Hamperl and Heller, 1934; Wilson and Pickering, 1937-8; Wilson and Byrom, 1939). Negative results may mean that there has not been enough time for hyperplasia or that the degree of increase in the blood pressure was insufficient. It seems that the dog often can tolerate prolonged experimental hypertension without exhibiting substantial arteriolar changes; on the other hand, it has been shown by Wilson and Byrom (1939), in the rat, that high blood pressure induced by ischaemia of one renal artery may lead to typical changes in the arterioles of the non-ischaemic kidney.

The observations of Wilson and Byrom were not accepted by Goldblatt and Kahn (1940), on the grounds that white rats are particularly susceptible to pyelonephritis, and the latter workers considered that the results obtained might have been explained by the development of this condition. Restall (unpublished observations) has shown that rats rendered hypertensive for a period of approximately one year by unilateral renal ischaemia exhibit arterial changes in the other kidney. His histological observations and the bacteriological studies by Kirschner rule out pyelonephritis in most of the experiments.

That high blood pressure gives rise to medial hypertrophy in the smaller arteries and in arterioles may be regarded as proved. There is also evidence that other arteriosclerotic changes, such as increase of elastic tissue and perhaps intimal hyperplasia (Restall, unpublished observations), may develop as the result of increased intravascular tension. The literature is summarized by Hueper (1944). The arteriolar changes secondary to high blood pressure are usually more pronounced in the kidneys than in other organs.

5. Ways in which Pathological Changes Induced or Accelerated by Hypertension may lead to Further Elevation of Blood Pressure

It seems probable that, irrespective of the cause, prolonged elevations of the blood pressure of sufficient degree both physiological and pathological, tend to be followed by processes which lead to the further elevation of the blood pressure, with the ultimate development of essential hypertension. Any pathological or physiological changes brought

about by the primary hypertension and leading to secondary rises of blood pressure could set up a vicious circle. At least five such mechanisms must be discussed.

(i) Inelasticity of Larger Arteries

In hypertension, arteriosclerosis of great vessels is accelerated with the loss of distensibility (Bramwell, 1924; Fahr, Davis, Kerkhof, Hallock, and Giere, 1932; Wiggers, 1938) causing systolic hypertension. It is stated that the mean blood pressure is not raised (Fahr, Davis, Kerkhof, Hallock, and Giere, 1932), and therefore it is uncertain whether such hypertension will or will not tend to accelerate arteriosclerosis and arteriosclerosis further. *It is not suggested that this systolic hypertension caused by decreased elasticity of large arteries is sufficient to explain the progressive increase of blood pressure, but that it is a factor which participates.*

(ii) Exaggerated Contraction of Hypertrophied Arterioles

Measurements of arterioles and small arteries in almost all tissues of the body, and notably in muscle, indicate that at a certain stage in the development of essential hypertension there is medial hypertrophy. It seems likely that more vigorous responses by hypertrophied blood vessels would account for the fact that both rises and falls of blood pressure in response to various stimuli are commonly exaggerated in essential hypertension. Experimental evidence in favour of this has been obtained by Restall (unpublished observations), who compared the response to adrenaline of blood vessels from chronically hypertensive and control rats, and found greater responses from the vessels of hypertensives, especially renal vessels. Even if medial hypertrophy does not of itself raise the blood pressure it seems probable that it would render other hypertensive agents more effective. *If the medial hypertrophy caused by blood-pressure elevations leads to further increase of the blood pressure another vicious circle has been set up.*

(iii) The Goldblatt Mechanism and Variable Reactivity of Blood Vessels to Pressor Agents

The suggestion has been made that essential hypertension might be due to the liberation of pressor substances from kidneys rendered ischaemic by arteriolar changes in the renal blood vessels (Goldblatt, 1947). The arteriolar changes in essential hypertension are most prominent in the kidney (Fahr, 1922; Fishberg, 1925; Russell, 1929; Moritz and Oldt, 1937; and others). I favour the view that such arteriolar changes, more particularly in the later years, may occur primarily, but some at least of them may be caused or accelerated by the prodromal rises of blood pressure referred to in the first part of this paper.

The experimental evidence that ischaemic kidneys sometimes liberate pressor substances is so strong that it may be taken as proved. The presence of some degree of renal ischaemia in almost all advanced cases, especially elderly cases, may be regarded as established. It seems probable that such renal ischaemia will cause a rise in blood pressure at certain stages and in certain cases of established essential hypertension. The suggestion has been made also that functional renal vasoconstriction might initiate a Goldblatt type of hypertension (Goldring, Chasis, Ranges, and Smith, 1941). At my suggestion Restall (unpublished observations) studied the response to adrenaline of blood vessels in rats rendered chronically hypertensive by unilateral renal ischaemia and in control rats. He found that vasoconstriction was much more pronounced in the vessels of the unoperated kidneys of the hypertensives than in the renal vessels of controls. Such observations indicate a means by which renal vascular changes may become progressive.

On the other hand, renal ischaemia is not always associated with an elevation of the blood pressure (Kimmelstiel, 1933; Cox and Dock, 1941). Whether the absence of hypertension is due to failure of the kidneys to release pressor agents, to the subsequent inactivation of such agents (Fasciolo, Houssay, and Taquini, 1938; Katz, Mendlowitz, and Friedman, 1938; Rodbard and Katz, 1941), to the operation of homeostatic controls preventing an elevation of the blood pressure, or even to antipressor agents, it is impossible to say at the present time. The experimental study of renal hypertension is made more difficult by the fact that the available experimental animals

behave dissimilarly (Braun-Menéndez, Fasciolo, Leloir, Munoz, and Taquini, 1946). In the rat and rabbit it has been suggested that, whereas the initial rises of blood pressure following renal ischaemia are due to the Goldblatt mechanism, the subsequent maintenance of the high blood pressure is effected by some other means. The application of the results to human hypertension remains uncertain. The processes whereby renal ischaemia leads to hypertension in experimental animals is complicated and not yet fully evaluated. Liberation of an enzyme-like substance, renin, from the ischaemic kidney acts upon a substrate-like substance, preangiotonin, which is a constituent of plasma, to form a pressor agent, angiotonin. The angiotonin causes vasoconstriction by a direct action on smooth muscle, but has a limited period of action owing to its enzymic destruction.

From the observations of Black (unpublished) it seems that, apart from destruction, the amount of circulating angiotonin could not be the only factor deciding the magnitude of blood-pressure increase. Black has shown that there is no consistent difference between hypertensives and normotensives in respect of their sensitivity to the pressor action of intravenous angiotonin. Some individuals are insensitive to doses of angiotonin which in others cause large rises in blood pressure. Vascular sensitivity to the pressor action of angiotonin runs parallel with sensitivity to the pressor action of S. methyl isothiourrea. A non-specific reactivity of blood vessels governs the pressor response as well as the amount of circulating angiotonin.

The formation of hypertensive agents depends upon the degree of ischaemia and the amount of renal tissue involved; and the rate of destruction of hypertensive agents is related to the amount of non-ischaemic renal tissue in the body. The kidneys both of essential hypertension and of elderly normotensive cases may have within them areas which are ischaemic and areas which are adequately supplied with blood. It is therefore possible that while parts of the renal tissue are forming, other parts may be destroying, the hypertensive agents. Increased formation of V.E.M. or decreased elimination of pressor amines by amine oxidase have been suggested as alternative or additional mechanisms by which renal ischaemia could cause blood-pressure elevations. *It seems clear, however, that elevated blood pressure favours renal arteriolosclerosis, and if this in turn gives rise sometimes to further elevations of the blood pressure due to the renal ischaemia a vicious circle would be set up.*

(iv) Elevations of the Blood Pressure Persisting After the Initial Cause has Ceased to Operate

(a) *Hypertension Persisting After Removal of a Single Ischaemic Kidney.*—In the rat the removal of the ischaemic kidney after several months of experimental hypertension did not usually restore the blood pressure to normal (Wilson and Byrom, 1941; Grollman, Harrison, and Williams, 1943; Patton, Page, and Ogden, 1943). It seems that in many cases pathological changes have developed in the unoperated kidney (Patton, Page, and Ogden, 1943; Restall, unpublished observations), and the persistence of the blood-pressure elevation has been attributed to these. Pickering (1945) has indicated the possibility of a non-renal mechanism. Likewise in the rabbit Grollman (1944) found that nephrectomy after ten weeks of hypertension from renal compression does not abolish the hypertension. In the dog the evidence is insufficient. It has been shown that removal of a single ischaemic kidney abolishes the hypertension in the dog if the removal is carried out within the first few weeks (Goldblatt, Lynch, Hanzal, and Summerville, 1934; Blalock and Levy, 1937; Houssay and Fasciolo, 1937; Verney and Vogt, 1938, 1943; Rodbard and Katz, 1939). Isolated experiments suggest that, in the dog, hypertension may persist if removal of the ischaemic kidney is postponed for three months or more. Goldblatt, however, reported an experiment in a dog with unilateral renal hypertension of nine months' duration which was completely cured by nephrectomy.

(b) *Hypertension Persisting After Bilateral Nephrectomy.*—Pickering (1945) has shown that blood-pressure elevations may be made to outlive the stimulus which produced them. He raised the blood pressure in rabbits by unilateral nephrectomy and constriction of the main artery of the remaining kidney, and noted that if hypertension had lasted but a few days and

the remaining ischaemic kidney was removed the blood pressure fell to normal in a few hours. If the hypertension had lasted seven weeks or more excision of the ischaemic kidney no longer removed the hypertension. The response of the blood vessels was altered as the result of the prolonged hypertension. There are clinical experiences which may be analogous. For example, where the blood-pressure rise due to toxæmia of pregnancy has been of short duration, even if high, termination of the pregnancy often is associated with a comparatively rapid fall of the blood pressure back towards normal. If, however, the blood-pressure rise has been of long duration the blood pressure may not return to normal for several months after the termination of the pregnancy, and in some cases a permanent hypertension results. The incomplete fall or absence of a fall of blood pressure following the removal of a unilateral ischaemic kidney even when there is good evidence that the remaining kidney is healthy (Abeshouse, 1941a, 1941b) may be another example.

Some observations concerning the effect of bilateral nephrectomy by Flemming (unpublished observations) on hypertensive rabbits confirm the observations of Pickering.

(c) *Experimental Audiogenic and Neurogenic Hypertension.*—Medoff and Bongiovanni (1945) and Farris, Yeakel, and Medoff (1945) showed that rats subjected for long periods to intense intermittent audiogenic stimuli developed elevations of blood pressure. Restall and Smirk (unpublished observations) confirmed these findings and found in agreement with Medoff and Bongiovanni that the blood-pressure elevations were not abolished by light or ether anaesthesia. We noted that the blood-pressure increase persisted for at least several months after the audiogenic stimulation ended, that there was no histological evidence of renal damage in the early stages of the experimental hypertension, and that the blood pressure remained elevated for 36 hours after bilateral nephrectomy. The possibility that the nervous system was damaged by supersonic waves has not yet been eliminated.

In some other experiments, however, rats were exposed first to a signal noise (buzzer), no question of supersonics being involved. The signal noise was followed by electrification of the cage causing a mild-to-moderate faradic stimulation of the rats' feet. This also led within a few weeks to a rise of blood pressure, though of smaller degree, which was not abolished by light ether anaesthesia. It seems that the initial blood-pressure elevation is due in this case to nervous stimulation, and that this has given rise to an increase in blood pressure which apparently is maintained by some process other than that which initiated the hypertension.

This would appear to be experimental confirmation in the rat of the suggestion that certain blood-pressure increases if frequent or prolonged enough may outlive the stimuli which caused them. These persisting blood-pressure increases in rats following audiogenic and electrical stimulation often persist after bilateral nephrectomy, and in this resemble those described by Pickering (1945) in rabbits after hypertension induced by renal ischaemia. Apart from the general resemblance there is as yet no evidence of a single underlying mechanism. The significance for human hypertension is undetermined.

(r) Absence of Appreciable Increase of Passive Resistance in Hypertrophied Vessels

The idea that pathological changes in the arterioles may result in a permanent increase in the peripheral resistance and thereby be responsible for continued elevation of the blood pressure was discussed by Volhard (1931). The elevation was looked on as being passive and anatomical rather than contractile in origin. The changes in the blood vessels outside the kidney, however, are thought to be insufficiently advanced to give support to this explanation. The considerable fall in blood pressure which may occur for a short time after sympathectomy, after nitrates, or from thiocyanate overdosage suggests that no great part of the peripheral resistance is the result of purely passive changes in the vascular bed. Restall perfused through the aorta the hind quarters of rats which had been hypertensive for a period of 12 to 18 months (approximately one-third to one-half of the normal duration of a rat's life), and, compared with normal rats, he found but little

difference in the peripheral resistance. It appears from this experiment that the continued high blood pressure was maintained by active vasoconstriction and even after one year only a minor part of the peripheral resistance of the lower limbs was of a passive character. I have not, therefore, been able to find experimental support for the idea that pathological changes in vessels lead in time to the development of any important generalized increase of passive peripheral resistance.

6. Other Factors which may Elevate the Blood Pressure

1. *Increased Reactivity to Blood-Pressure-Raising Reflexes in Cases of Arterial Hypertension.*—High reactivity to the cold pressor test (Hines and Brown, 1935) and to the blood-pressure-raising reflex from muscle (Alam and Smirk, 1938) is often encountered in essential hypertension, but this does not by itself explain a high level of the resting blood pressure. It is probable that a high degree of reactivity of the blood pressure to blood-pressure reflexes may express itself in daily life by abnormally strong and frequent blood-pressure variations. The blood pressure from this cause may be found at a higher level in the non-basal conditions which ordinarily are present at the time of measurement. The reactivity to blood-pressure-raising reflexes increases with age, but to a greater degree in essential hypertension than in health (Alam and Smirk, 1938; Russek and Zohman, 1945).

2. *Natural Increase of Blood Pressure with Age.*—The recorded blood-pressure averages increase with age. To some extent this is due to the effect of including the pressures of hypertensive individuals in the figures. The general impression, however, is that there is also an increase in the average blood pressure with age which does not depend on the inclusion of hypertensives. This "natural" blood-pressure increase with age is likely to be one of the several factors responsible for the increase in the incidence of essential hypertension in the later years of life.

3. *Alteration in the Response of the Carotid Sinus to Blood-Pressure Increase.*—While my observations confirm Pickering, Kissin, and Rothschild (1936) in their view that the carotid sinus mechanism in cases of essential hypertension responds to digital stimulation, I found that in response to blood-pressure increases produced reflexly the pulse rate tends to rise instead of falling in most cases of essential hypertension, the natural relationship between pulse rate and blood pressure being reversed (Alam and Smirk, 1938). A corresponding observation was made previously by MacWilliam (1925). A possible interpretation of this is that the carotid sinus offers a less effective control over the blood-pressure level in cases of essential hypertension.

4. *Increase of the Secretions of the Suprarenal Gland.*—The suggestion has been made that cortical hyperadrenia may be concerned in the pathogenesis of essential hypertension (Perera, Knowlton, Lowell, and Loeb, 1944; Perera and Blood, 1947a, 1947b). In terms of the present hypothesis, blood-pressure increases of suprarenal origin or any other, if sufficiently frequent and prolonged, would be expected to play their part in pathogenesis.

Comment

If elevation of the blood pressure in essential hypertension depends upon the total effect produced by the combined action of several components, it becomes important to know whether the magnitude of the total effect is equal to the sum of the effects of the various components acting separately. The answer appears to be that the blood-pressure rise produced by two blood-pressure-raising stimuli acting simultaneously is less than the sum of the blood-pressure rises produced by the two stimuli acting separately (Bruce, Martin, and Smirk, 1945). This may be a part of the

explanation of why the rate of increase of the blood pressure is slowed up as higher levels are attained.

No reference has been made earlier in this paper to malignant hypertension, largely because it is thought that malignant hypertension is something other than a severe or accelerated form of essential or benign hypertension. After a survey of 169 consecutive deaths in hypertensive individuals, residents of the province of Otago, New Zealand, and on the basis of clinical experience in that province, Istad and Smirk (1948) reached the conclusion that, whereas benign hypertension is a very common condition, malignant hypertension and the classical advanced omerulonephritis are both most exceptional, particularly the former. It is sometimes stated that malignant hypertension is an accelerated form of benign hypertension. But experience goes to show that benign hypertension in Otago province does not differ fundamentally from benign hypertension in other countries, although its course appears to be rather milder; yet malignant hypertension is decidedly uncommon. It seems very probable, therefore, that the condition of malignant hypertension is not merely an accelerated form of benign hypertension but involves some additional factor over and above those responsible for benign hypertension. It is of great interest that there is also a correspondingly low incidence of chronic glomerulonephritis in Otago province. It is clearly worth considering whether the infrequency of advanced chronic glomerulonephritis and of malignant hypertension in this province is in some way related to the absence of a common aetiological factor.

Summary

It seems probable that there is no single or simple primary use of essential hypertension.

It is thought that the disorder may originate in some cases from the simple overactivity of physiological processes, whereas in other cases pathological changes such as renal arteriolosclerosis may be primary.

It is suggested that the blood-pressure increases are of composite origin but that these increases, if frequent, high, or prolonged enough, give rise to a number of pathological and functional changes which tend to maintain or elevate the blood pressure further. Once this self-perpetuating cycle of changes has been set up the condition may be described as essential hypertension. Under-average blood pressures are associated with a much decreased incidence of essential hypertension in later life. It is difficult to explain this protective influence of low blood pressure except by the hypothesis that the tendency to develop high blood pressure in later life is influenced strongly by the precise level of the blood pressure even when this lies within the normal range.

Examples of factors various combinations of which may raise the level of the blood pressure enough to enhance strongly the liability to the subsequent development of essential hypertension include: certain geographical environments, race, heredity, emotional lability or disposition to over-alertness and inattention, occupations or domestic environments involving a tendency to stress and strain, over-average liability of the autonomic system to respond by vasoconstriction to tenseness and emotion, physical activity or metabolic stimuli, over-average body weight or sthenic habitus.

Elevations of the basal pressure are likely to throw greater strain on the heart and on small arteries and arterioles than the elevations of the supplemental pressure. The degree to which blood vessels are able to withstand exposure to over-average blood pressure or vasoconstriction without undergoing pathological change varies from one individual to another and is likely to have an important influence both on the rate of increase of the blood pressure and on the development of complications.

Examples of a number of pathological and functional changes which in various combinations it is thought might be responsible for further elevations of the blood pressure are cited and discussed in the text. These include: (a) inelasticity

of large arteries; (b) exaggerated contraction of hypertrophied arterioles; (c) the release of pressor agents from ischaemic kidneys; (d) to a very minor degree, increased passive resistance of hypertrophied arterioles; and (e) an unknown non-renal factor or factors capable of perpetuating certain blood-pressure increases after the primary exciting causes of these increases have ceased to operate. Other factors are referred to which probably contribute increments of pressure increase.

The fundamental unity of the clinical picture in essential hypertension is not dependent upon the blood-pressure elevation being regarded as the result of a single or simple pathological process. It is due to the fact that the clinical manifestations and complications are due almost entirely to events which are secondary to a single characteristic of the disorder—namely, high blood pressure brought about mainly by vasoconstriction.

The above general hypothesis holds that elevations of blood pressure in man and certain other mammals tend to be self-perpetuating. It is to be expected, therefore, that the cycles of changes concerned in the secondary elevations of the blood pressure which occur in essential hypertension will be responsible in part for the perpetuation, and perhaps for the further increase, of blood pressure in certain other conditions such as post-toxaemia of pregnancy, cortical hyperadrenia, and some cases of chronic pyelonephritis, medullary hyperadrenia, and chronic nephritis.

There is evidence suggesting that malignant hypertension is something other than an accelerated form of benign or essential hypertension.

Grateful acknowledgment is made to Miss Walsh and Mrs. Tyson for extensive secretarial help, and to the Medical Research Council of New Zealand for grants-in-aid.

THE ROLE OF INFECTION IN GRANULOPENIA

BY

KENNETH ROBERTSON, M.D., F.R.C.P.

Physician, Royal Hants County Hospital, Winchester, and
 Royal South Hants Hospital, Southampton

In 1922 Schultz first reported a condition of severe and progressive oral sepsis associated with granulopenia, which often ended fatally. There can be no doubt that in the earlier cases the importance of sepsis was realized and stressed, but during the twenty years which followed Schultz's paper the aetiological emphasis shifted from infection to the leucotoxic drugs, the administration of which often coincided with the appearance of "malignant neutropenia," as this syndrome was now called.

Reports of cases associated with the taking of compounds containing amidopyrine began to appear on the Continent in 1930, and later in this country. The evidence against these drugs seemed irrefutable, particularly when it was shown that, in some patients who had recovered, a further small dose immediately produced a profound fall in the number of circulating granulocytes. With further experience other therapeutic agents fell under suspicion, and cases of dangerous neutropenia were reported after the use of organic arsenic, gold salts, sulphonamides, and, more recently, the thiouracils. This list is by no means complete, but is sufficient for the present purpose.

As familiarity with the condition increased, more and more importance was focused upon the leucotoxic agent, while the infection which invariably accompanied the condition came to be regarded as a purely secondary matter, due to invasion of the defenceless organism by bacteria. Thus Wilkinson (1936) uses such phrases as "the primary cause is clearly not bacteriological" and "it is apparently true, however, that the oral, throat, and other ulcerative or necrotic lesions are secondary to the blood condition, and not vice versa."

This view has undoubtedly held the field with little or no question, though all writers on the subject have referred to the fact that malignant neutropenia is from time to

time encountered in certain severe infections, particularly staphylococcal septicaemia and osteomyelitis, pneumonia, and liver abscess, when none of the usually accepted leucotoxic drugs have been used. Witts (1936) points out that patients whose white cells have been depressed by one of these drugs may or may not develop the acute illness, depending upon chance exposure to infection. He also refers to animal experiments which seemed to show that such drugs make impossible the normal leucocyte response to infection.

Dameshek and Wolfson (1942) made a preliminary report on the treatment of agranulocytosis by sulphonamides. Nixon, Eckert, and Holmes (1943) described three cases in which agranulocytosis developed while infections were being attacked by sulphadiazine. Instead of withdrawing the drug, it was continued in larger doses, with the result that the blood pictures returned to normal and the patients recovered.

Since these papers, the part played by infection in granulopenic conditions has assumed increasing importance. There can be no doubt that many physicians have accepted Dameshek's advice regarding treatment and no longer worry about the blood picture, concentrating their efforts in overcoming the infection which is threatening to overwhelm the victim.

Boland, Headley, and Hench (1946) reported the cure of a case of total agranulocytosis following the use of gold—a particularly fatal combination—by means of penicillin. In the same paper they refer to fourteen other cases associated with various drugs successfully treated in the same way.

Nevertheless, Israëls (1948), writing of penicillin treatment, says: "Several cases have been reported in the literature, but the results are not very convincing. If there is evidence of sepsis, it is clear that penicillin should be given promptly." Acute agranulocytosis unassociated with sepsis must be exceedingly rare, though Hickie (1948) has described the case of a 70-year-old man whose blood appears to have been almost devoid of cells of the granular series for a period of three years, and in whom it seems that sepsis was infrequently seen, and only as mild superficial episodes.

In March, 1946, I had under my care a woman who developed a complete agranulocytosis while undergoing treatment with gold for rheumatoid arthritis. Two previous similar cases under my care had quickly ended fatally in spite of vigorous treatment, using all the recognized methods of bone-marrow stimulation. In this case penicillin was added to the treatment, and recovery was prompt and complete.

A Series of Cases

While serving on the Medical Division of a military hospital during 1947 I had the opportunity of treating a number of cases in which severe granulopenia complicated arsenical treatment of syphilis. In addition to N.A.B. all these cases were receiving bismuth, an agent which appears in the list of leucotoxic materials given by Beaumont and Dodds (1947), though I have been unable to discover the report of any case in which granulopenia followed the use of bismuth without arsenic.

In the earlier cases British anti-Lewisite (BAL), "pentide," blood transfusion, ascorbic acid, liver extract, and other bone-marrow stimulants were used in addition to penicillin. In six subsequent cases penicillin alone was employed, with very satisfactory results. McManus (1946) records a similar experience. A case of "arsenical agranulocytosis" treated with BAL and pentide failed to improve until penicillin was added to the treatment. In a second case cure was rapidly achieved by the use of penicillin alone.

In every instance sepsis, particularly in the mouth, was striking and severe, and haematological improvement went hand in hand with resolution of the infection. This was so striking that I wondered if the infection was of greater importance in the causation of the condition than the arsenic. I wondered, too, if it could be shown that cure could be assured, provided the infection was controlled, even when further arsenic was administered. Further cases of arsenical granulopenia provided the material necessary to put this view to the test.

Several doses of N.A.B. were given to a man (Case 1) immediately after his recovery from the acute illness, for which he had been treated with penicillin alone. These produced no untoward effects either clinically or in the blood picture, and he went on to complete his full course of antisyphilitic treatment. In Case 2 the same procedure was followed, with the same result.

It now remained to observe the effect of arsenic administered before the acute illness had been controlled. In Case 3, 0.6 g. of N.A.B. was given 24 hours after starting penicillin. This appeared to make no difference to the patient's response to treatment. In Case 4 a full dose of N.A.B. was given before starting penicillin treatment. In this case recovery was somewhat delayed, but it was discovered that the infection involved a penicillin-resistant strain of staphylococcus, and the local sepsis did not respond until very large doses of the antibiotic had been given. The haematological improvement followed immediately upon control of the local infection. Reports of the four cases are given below.

Case 1

A private soldier aged 25 was admitted seven weeks after starting routine treatment for a dark-ground-positive chancre. Treatment had been interrupted by mild febrile reactions to arsenic injections, and on admission he had received 3.15 g. of N.A.B. and 1.4 g. of bismuth in addition to 4 mega units of penicillin.

He presented with gross oral sepsis, the gums, which were swollen and congested, being particularly affected. His temperature was 104° F. (40° C.) and his pulse rate 110. There was considerable adenopathy involving all the superficial glands, his spleen was palpable, and he was covered with a well-marked pigmented secondary syphilide. His white cells numbered 5,000 per c.mm., only 5% of which were of the granular series (total polymorphs 250). The Kahn test was positive, two nits, and the Paul-Bunnell test negative. He was treated with 0.000 units of penicillin three-hourly. At the end of 48 hours, with his temperature falling and his mouth improving, his white cells numbered 6,000, 24% of which were granulocytes (total 1,440). On the fifth day his temperature was normal, and his mouth almost normal, while his white count had risen to 7,600, 13% polymorphs (total 3,268). Two days later, the penicillin being continued, 0.3 g. of N.A.B. was injected intravenously. There was a slight febrile reaction, but his white cell count remained satisfactory; indeed, when comparing counts made immediately before the injection with those made at 12 and 18 hours after the injection there was a definite increase in the number of circulating polymorphs.

Two days later a further injection of 0.45 g. of N.A.B. was given. To this injection there was no reaction, but 36 hours later he showed a leucocytosis of 20,000 with 65% polymorphs (total 13,000). During this stage of treatment penicillin cover had been maintained. This was now discontinued, and he subsequently completed his course of antisyphilitic treatment with N.A.B. and bismuth without further incident, his blood count remaining normal throughout.

Case 2

A soldier aged 24 should have received his final dose of N.A.B. and bismuth on July 5. This was withheld because of swollen gums, and he was referred to the dental department. He was admitted three days later with a temperature of 104° F.

(40° C.), pulse 130, and showing gross swelling of his lower jaw, gingivitis, and many boils on the arms and trunk. He had received 7.5 g. of N.A.B. and 2.6 g. of bismuth. His blood showed 3,650 white cells per c.mm., with 10% polymorphs (total 365). The Kahn test was negative. Penicillin was started 50,000 units being given every three hours. His response was immediate, and in 24 hours his temperature had fallen to 100° F. (37.8° C.) and there was considerable local improvement, while his polymorph count had risen to 896. Three days later the condition of his mandible and gums seemed normal while all his boils had healed and his white cell count showed that 56% of 3,600 cells were polymorphs (total 2,016). Penicillin was discontinued, and two days later, with a normal white cell count, he was given 0.45 g. of N.A.B. intravenously. Thirty-six hours after the injection he showed a leucocytosis of 14,000 with 64% polymorphs (total 8,960). Two weeks later his white cell count was normal.

Case 3

A 43-year-old officer received his fifth injection of arsenic on Oct. 16. The total amount of arsenic received was 2.55 g. On the 18th his mouth and gums became painful. He was admitted on Oct. 25 with high fever, great swelling of the gums and buccal ulceration. His white cell count was 6,200 per c.mm. with 18% polymorphs (total 1,116). Treatment was withheld and the next day his count had fallen to 5,100, with 16% polymorphs (total 816). Penicillin was now started—50,000 units three-hourly—and by the 27th, with clear-cut clinical improvement, his white cells had increased to 6,000, 32% of which were polymorphs, 9% being eosinophils (total granulocytes 2,460). N.A.B. 0.6 g. was given intravenously on this day. An urticarial rash resulted, lasting 24 hours. Next day, with his temperature normal and showing marked local improvement, his white cell count had improved to 7,100 (52% polymorphs, 7% eosinophils; total granulocytes 4,189). From this point his illness rapidly resolved, and he was discharged to continue his course of antisyphilitic treatment, without further episode.

Case 4

A private soldier aged 20 was admitted on Dec. 3. He had received 1.95 g. of N.A.B. and 0.8 g. of bismuth. The earlier stages of his arsenical treatment had been decelerate on account of some skin reactions. Two days before admission he had felt ill, with pain in his left cheek. The next day the cheek was swollen and a sty had developed on the right lower lid. He reported sick and was sent to hospital 24 hours later. He then had a temperature of 104° F. (40° C.) and showed all the signs of considerable toxæmia. On the buccal surface of the left cheek there was a deep painful ulcer. The lower lid had a staphylococcal infection, and furuncle was present on his chin. A blood count showed 4,200 white cells per c.mm., 2% of which were polymorphs (total 84). Before the beginning of treatment he was given 0.6 g. of N.A.B. Two hours later penicillin was started in 100,000-unit doses every three hours. The next day his white count had fallen to 2,400 and no polymorphs could be seen in a smear. Subsequent counts were as follows:

Date	Leucocytes	Polymorphs	Eosinophils	Total Granulocytes
Dec. 5 ..	2,600	4%	13%	442
" 6 ..	4,300	6%	8%	602
" 7 ..	4,000	10%	3%	520
" 8 ..	5,500	15%	7%	1,210
" 9 ..	4,400	17%	4%	924
" 10 ..	8,800	14%	9%	2,024
" 11 ..	7,000	36%	4%	2,800
" 12 ..	7,150	35%	8%	3,074
" 15 ..	9,350	46%	6%	4,862
" 20 ..	8,000	60%	2%	4,960

On Dec. 6 the staphylococcus obtained from his lesions was reported to be penicillin-resistant. The dose of penicillin was immediately doubled. At this time, though his temperature had subsided and his general condition was excellent, the buccal ulcer was showing no signs of healing. During the next few days this situation was reversed and the ulcer healed steadily.

It will be seen that restitution of the blood picture was delayed, and it seems reasonable to assume that this was

related to the fact that the infecting organism proved relatively resistant to penicillin and that it was not subjugated until the dosage was considerably increased. This patient received in all 15 mega units of penicillin.

Discussion

In this small investigation it appeared that infection was playing the major part in the aetiology of the condition, and that its control allowed recovery of the bone marrow, a recovery which further arsenic was unable to prevent.

In other conditions associated with granulopenia I have noticed serious deterioration as a result of superadded infection. A man convalescent from glandular fever sustained a streptococcal infection of his throat. His polymorphs promptly fell from 1,800 to 90 per c.mm., to rise again immediately the infection had been subdued by penicillin. A woman suffering from chronic lymphatic leukaemia developed gross infection in her mouth and throat. This resulted in a grave illness, with high fever, widespread purpura, and a rapid fall in the haemoglobin level, which reached 25%. Treatment with parenteral and intraoral penicillin rapidly overcame the infection, the fever fell to normal, the mouth lesions healed, the purpura vanished, and the haemoglobin began to rise, eventually reaching over 100%. She has remained well during six months' subsequent observation, though her blood picture is still, of course, that of chronic lymphatic leukaemia. In other cases of leukaemia acute and threatening episodes have been initiated by sepsis, the control of which has resulted in temporary improvement in the patient's condition.

There seems to be little doubt that a functionally damaged bone marrow is particularly vulnerable to the toxins resulting from sepsis. It is well known, for example, that infection can interfere with the full therapeutic effect of liver extract in the treatment of Addisonian anaemia.

The factors giving rise to neutropenia are doubtless multiple. In addition to the part played by leucotoxic drugs—and no one will challenge this factor—it seems that idiosyncrasy, sensitization, age, sex, and endocrine factors must all be taken into account. But it may well be that infection, which is, I believe, the only factor common to almost every case, is the most important of all. A recognition of this possibility is clearly of considerable therapeutic and preventive importance. It would seem wise to exclude sepsis in cases of rheumatoid arthritis and thyrotoxicosis before embarking upon treatment with gold or the thiouracils. At the same time patients undergoing treatment by any of the recognized leucotoxic drugs should be warned to avoid infection and to report the smallest infective process immediately. Printed instructions might be valuable from this point of view. It is doubtful if the white cell count is of any value in giving warning of white cell depression, and may even lead to a false sense of security.

It has always been said that the appearance of a blood dyscrasia while undergoing treatment by any of these drugs precludes for ever the use in such a patient of the particular material thought to have been causative. The observations recorded here suggest that this dictum may not need to be adhered to when there are indications for further administration of the offending preparation. McGibbon and Glyn-Hughes (1943) came to the same conclusion after describing a case of agranulocytosis following arsenic.

In 1942 a fulminating case of agranulocytosis under my care, following the use of sulphapyridine, was given after recovery 3 g. of the drug by intravenous injection. Frequent white cell counts made during the subsequent 48 hours revealed no fall in the number of granulocytes.

Conclusions

It is suggested that in conditions of serious neutropenia infection plays a predominant part; that in its prevention, while undergoing treatment with possibly leucotoxic drugs, avoidance of infection, both endogenous and exogenous, is of more importance than repeated blood examinations; and that in the treatment of the established condition attention should be centred upon the immediate arrest of the infective process by the free use of the most suitable specific drug, which at present is likely to be penicillin in most cases. It should be given in large doses, in the region of 1 mega unit daily. In these circumstances pentide, blood transfusion, etc., may with advantage be withheld during the first 72 hours. If there has been no response at this stage pentide should be started and continued until response is well established. Fresh blood, folic acid, pyridoxin, ascorbic acid, liver extract, and thyroid may all be useful in individual cases. Where there has been satisfactory response to penicillin alone it may be possible to resume the supposedly leucotoxic drug, if necessary.

My thanks are due to the Director-General, Army Medical Services, for permission to publish this paper, and to Brigadier F. J. O'Meara, Consulting Physician, B.A.O.R., Colonel C. A. Gavan Duffy, Officer Commanding Medical Division, 94th (Hamburg) British Military Hospital, Colonel F. E. Buckland, Director of Pathological Services, B.A.O.R., and Captain W. T. Hendry, for their interest and help in this investigation.

INSTRUCTION OF THE MEDICAL STUDENT IN PAEDIATRICS

AN INSIGHT INTO FAMILY PRACTICE

BY

W. S. CRAIG, M.D., F.R.C.P.Ed., M.R.C.P.
F. CHARLOTTE NAISH, M.D.

AND

M. F. G. BUCHANAN, M.B., Ch.B.Ed., D.Ch.

Instruction of the medical student is concerned primarily with the training of the future family doctor. Undergraduate training suffers from having to be provided under conditions dominated by hospital considerations of disease. As a result the recently qualified doctor entering general practice has to adjust his outlook. He is not long in practice before he realizes that many of the problems which appeared simple of solution when seen in hospital are complex when considered in relation to the needs of the home. Short of restoring the old-time apprenticeship system it is difficult to see how this handicap can be completely offset.

The handicap applies particularly to undergraduate study of health and disease in infancy and childhood. Ward instruction is deficient because of the absence of the mother and of any visual reminder of home conditions. The

deficiency is made good in part, but only in part, by teaching in hospital out-patient departments, at infant-welfare sessions, and at school medical inspections. These sessions, no matter how efficiently they are run, are apt to suffer from a routine intended to cope with a considerable number of children in a set period of time. Health and disease in childhood are studied in an atmosphere of organized efficiency rather than one of intimacy of understanding. The student is left with an impression of a limitless tide of "cases," some of interest, others of doubtful interest. The tide is apt to flow with such speed that in his concern over physical findings the student is insufficiently impressed by the human family problem presented by each child. Nor can the hospital clinician, be he ever so able a teacher, convey to the students that full depth of understanding of mother and child and family circle which makes for successful care of child life in general practice.

Experiment at Leeds

The medical student taking out his course of clinical instruction in paediatrics and child health at the University of Leeds is given opportunities of seeing healthy and ailing children in hospitals and at clinics, handicapped and "deprived" children in day and residential homes, and some of the homes from which sick children have been admitted for treatment in hospital wards. In the course of his studies the same student meets practitioners on the visiting staffs of hospitals and in the employ of local authority child-health services, nurses working in hospital or as health visitors, school nurses, and district nurses or district midwives. He is given a didactic lecture by a family doctor on the theme of paediatrics as met with in general practice, but until recently has not seen the family doctor at work.

We are convinced that the family doctor has a vital part to play in care of the child in health and disease. We are equally convinced that training of the future doctor in paediatric care would derive immeasurable benefit from early insight into such care as is provided in the course of everyday general practice. Ourselves (W.S.C. and F.C.N.) brought up from childhood in the households of family doctors, we are acutely aware in our professional work to-day of the debt we owe to that privileged experience of the past. Over a number of years one of us (F.C.N.) has made a special study of infants and children seen in the course of day-to-day family practice. Study pointed to the desirability of expanding the range of service offered to mothers and children in practice. One way in which expansion was developed was to reserve an afternoon each week for consultations for mothers and their children. In effect a clinic was established as an integral part of the activities of the family practice. The clinic proved a success from the start and has now run uninterruptedly for almost two years. There is implied recognition of its value in the authority recently given by the local executive council to continue the established policy of reserving one afternoon each week for mothers and children.

We felt that the training in paediatrics of the future general practitioner would benefit by insight into the work of a clinic conditioned by the circumstances of family practice. Experimental arrangements were therefore made to enable students, while attached to the University Department of Paediatrics and Child Health, to visit the clinic. We are satisfied that the arrangements have proved their value. The purpose of this paper is to give an outline of the arrangements and their results, because it is considered they indicate means whereby undergraduate, and indeed postgraduate, instruction of the medical student can be widened and improved.

The General Practice

The practice is one of a number in a non-university city with an approximate population of 100,000. The bulk of the work is concerned with the families of manual labourers, clerical workers, and shop employees. Of other persons on the practice list a small number are members of professional and military families. Midwifery constitutes an important part of the activities of the practice, and in the matter of social groups reflects the distribution characteristic of the practice as a whole.

The Clinic

The clinic is held in the family doctor's private house, which is situated in a working-class district. Accommodation consists of a weighing-cum-secretarial room, a waiting-room, and a consulting-room with screened examination couch. The accommodation is in fact the "surgery." Furnishings include low seats suited to use by nursing mothers.

Sessions are held weekly. The family doctor (F.C.N.) has the assistance of a secretary and nurse, and has recently been offered the services of a health visitor by the maternity and child-welfare authority. Attendance is on a voluntary basis and by appointment. Mothers who attend with their babies consist of those delivered by the doctor, of those who are on the doctor's National Health Service list but who have been delivered in hospital or by a midwife, and a few referred by the doctor's partners in the family practice. Of newly born infants in the practice approximately 80% attend the clinic. Mothers are advised to attend weekly until the baby is 3 months old, fortnightly during the next three months, and thereafter at monthly intervals until the baby reaches his first birthday. Older children attend at longer intervals or at any time, prior to school age, when their mothers wish advice on account of any difficulties in upbringing.

Attendances average twenty-six a session. All children are weighed, and individual records are kept on separate cards. Duplicate cards are kept by the mothers. At any one session rather more than 50% of those attending are seen personally by the doctor at the request of the mother, at the instigation of the nurse, or in accordance with arrangements made by the doctor at the time of a previous visit.

Work of the Clinic.—The ages of children attending range from a few weeks to 5 years. Infants predominate. All children are accompanied by their mothers, who know that they must not bring any child thought to be incubating or harbouring infection. It is one of the objects of the clinic not to divorce care of the infant from care of the mother or family. Health and disease are not arbitrarily differentiated. General management, the promotion of health, and the prevention of disease receive equal attention. The indications for consultations arise from an infinite variety of circumstances. They include comprehensive routine inspections; the supervision of infant feeding, whether breast, complementary, or wholly artificial; attendance for vaccination or immunization; requests for advice concerning symptoms which, were there not a clinic, might be ignored; family problems such as those arising from ill-health of the mother or from enuresis on the part of the child; and social problems such as those concerned with adoption and illegitimacy.

Arrangements for Medical Students

Attendance at the clinic is entirely voluntary. Provision is made for three students accompanied by a registrar (M.F.G.B.) to be present at each session. A number of

factors, including those related to distance and transport, make it impossible to arrange for any one student to be present at more than one session. At the time of his visit the student is encouraged to discuss the individual problems he has seen and any general considerations which particularly interest him.

All students have taken advantage of the opportunities offered them. They know they are taking part in an educational experiment. No attempt has been made to influence them in their views, and particular care has been taken not to initiate comparisons concerning different services for the care of child life. The students have willingly co-operated when asked after their visit to give a written account not so much of their impressions concerning detail as of their reactions to inclusion of the visit in the course of their training.

The Student's Reaction

A point of practical importance is that at no time has there been any unfavourable reaction to the presence of students on the part of mothers attending the clinic. As to the students themselves, while some few were constructively critical of certain aspects of the arrangements made for them, all testified to the value of their visits to the clinic. Many were unreservedly enthusiastic. Significance attaches to the reasons given for their opinions.

Almost all the students stressed that the visits had given them their first opportunity to "see general practice in operation." Of those who made this comment a number wrote of having appreciated for the first time the part which the family doctor can play in the care of child life in health and disease. Reading their remarks, it is evident that a number of students had had borne in on them how many of the children they see in the hospital out-patient department could be properly dealt with in the more suitable environment of a family doctor's consulting-room. Others, again, were impressed by seeing conditions which are rarely encountered in hospital but which, although they may have no serious immediate clinical significance, bulk more largely in general practice.

Most of the students remarked upon the advantages to child care of the mutual understanding and trust which it is within the power of the general practitioner to establish with the families he attends. Other students appreciated the initial advantage possessed by the family doctor whose care of children starts in the form of antenatal supervision of the mothers and who knows the background and capabilities of families in his practice. A number of students, men and women, sensed the benefits to infant feeding of supervision being undertaken by a doctor herself the mother of a family. Women among the students realized that marriage and a family do not necessarily debar a woman from making a vital and special contribution to child care in general practice.

We consider that the various views expressed by those visiting the clinic support the opinion that the experiment has justified itself. Evidence in favour of this opinion is to be found from the following extracts from notes sent in by three of the students who have taken part in the experiment. Telling of his outlook before visiting the clinic, one student wrote: "As a medical student one of the impressions I had conceived of general practice was that any case which required a little more trouble taken over it than normal was immediately referred, especially in paediatrics, to the already overworked hospital."

Another student wrote: "It [the visit] helped my sense of proportion in realizing the great value of the general practitioner in the promotion of child health." A third student summed up his impressions as follows: "The visit

made me realize that general practice is not static and can be made progressive . . . and can provide intellectual satisfaction."

Summary

Measures for the care of child life must be based upon the home. The family doctor has a vital part to play in any such measures. If it is to fulfil its primary function medical training of the undergraduate must be directed towards preparation for family practice. Teaching instruction in the care of child life is handicapped by difficulties in the way of giving the medical student practical insight into conditions prevailing in family practice.

An educational experiment is described which is intended to offset these difficulties in part at least. It is considered that the experiment has been a success, is capable of further development, and might be extended to a wider field of medical training than that concerned solely with health and disease in childhood.

INTERMENSTRUAL PAIN (THE "MITTELSCHMERZ") AND THE TIME OF OVULATION

BY

P. L. KROHN, B.M., B.Ch.

(From the Department of Anatomy, the Medical School, Birmingham University)

Cyclically recurring pain in the pelvis which can be related to the phases of the menstrual cycle is not uncommon in women. The condition was described by Priestley as long ago as 1872, although it is just possible that his observations were confused by the coexistence in his patients of chronic appendicitis, which at the time he wrote had not been defined as a clinical entity. Subsequent reports, in which corresponding pelvic pains have been referred to, mainly concern acute conditions that have called for operation, and in many instances laparotomy at the time of the pain has disclosed a recently ruptured ovarian follicle.

The periodicity of intermenstrual pelvic pain is one of the many signs that have been taken to indicate the time of ovulation in women. In view of the very clear-cut symptoms over a long period it is of interest to report the following case history.

Description of Present Case

The patient is a married woman aged 28 in whom cyclical intermenstrual pain has been recorded without interruption during the last 4½ years. It has occurred over at least seven years, but at first it was irregular. She has no recollection of similar pains before the age of about 16.

The pain is characteristic and easily recognized. It lasts for no more than 24 hours, and varies somewhat in intensity from time to time. It is never severe and can be controlled with simple analgesics. It begins suddenly in one or other iliac fossa and is gradually referred to the pubes, from which it spreads as a generalized pelvic pain.

The occurrence of the pain and the menstrual periods from April, 1944, to November, 1948, are charted in Fig. 1. The Table shows the duration of the two "phases" of the cycle. The following points may be noted.

Table Showing Distribution of Duration of Phases of Menstrual Cycle

	Duration in Days														
	10	11	12	13	14	15	16	17	18	19	20	24	25		
Ist day of menstruation to mittelschmerz					1	6	8	13	6	4	2	2	2		
Mittelschmerz to onset of menstruation	1		10	22	7	1	1								

1. The onset of the pain is regular. The mean interval from menstruation to the onset of the pain is 17.3 ± 0.33 days, and from the pain to the beginning of menstruation 13.0 ± 0.15 days. In agreement with most other statistics on the duration of the pre-ovulatory and post-ovulatory phases of the menstrual cycle, the second phase has a significantly smaller variance than the first pre-ovulatory phase (see Table). Although the length

of one of the later cycles was prolonged to 39 days, the mittelschmerz occurred as usual 13 days before the next period. Presumably the extra length of the cycle was due to some interference with normal follicular development.

2. In July, 1944, the patient wished to become pregnant and was advised to regard the mittelschmerz as the most likely indication of the time of ovulation. Ten days after the mittelschmerz in that cycle, and before the next period was due, the patient correctly believed that she was pregnant. No further pains were noted during either her pregnancy or her lactation. About three weeks after the end of lactation the pain was again recorded, and was followed ten days later by the return of menstruation. Since then it has continued its regular rhythm without interruption.

3. The pain has occurred 29 times on the right side and 14 times on the left. This predilection for the right side is significantly different from a 1:1 ratio for the two sides. Similar differences in favour of the right side have been reported for ovulation in the sheep (McKenzie and Terrill, 1937) and the monkey (Morse and van Wagenen, 1936), and, assuming that the pain indicates ovulation, the observed ratio in this case does not differ significantly from the figures reported by these workers. There does not seem to be any regularity of alternation from left to right side. The pain has never occurred twice in one cycle.

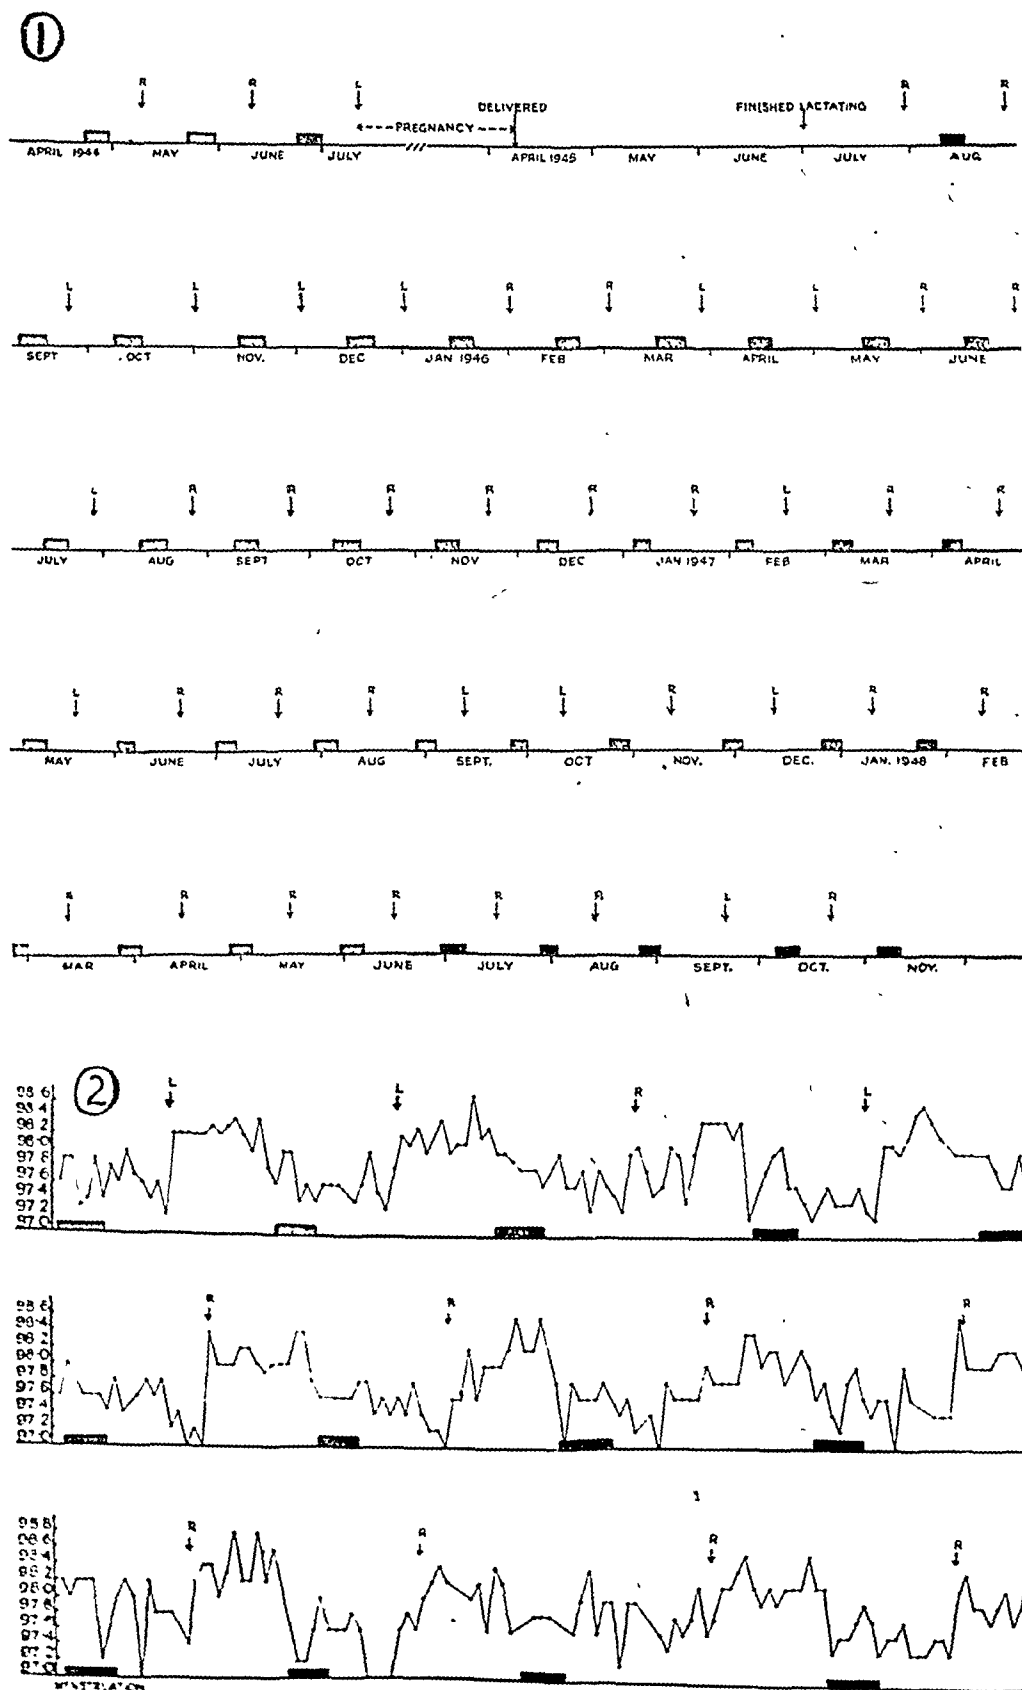

FIG. 1.—Menstrual cycles from 1944 to 1948. Occurrence and side of mittelschmerz are indicated by the arrow and R or L.

FIG. 2.—Fluctuation in daily waking oral temperature correlated with mittelschmerz, which is indicated by arrows.

Correlation of Mittelschmerz with Fluctuations in the Waking Oral Temperature

Since fluctuations in the body temperature are now widely used to indicate the time of ovulation a record of the daily waking oral temperature has been kept for the last 13 cycles. The results are plotted in Fig 2, the mittelschmerz being indicated by arrows.

The temperature recordings conform in general to the usually accepted pattern, though they are not so clear-cut as some that have been published. In the middle of the cycle, however, there is usually a slight fall in temperature, followed by a steep rise to a plateau, which is maintained until near the onset of the subsequent period. Occasionally this rise is indistinct.

An independent observer was asked to estimate the most likely time of ovulation from temperature charts alone. In eight of the 14 cycles ovulation, as judged in this way, agreed with the day of onset of the mittelschmerz. In three cycles the estimate was one day early, and in three it was one day late.

A change in the temperature curve, particularly when the whole chart is available and when attention is directed to the mid-cycle, is at best only indirect evidence of ovulation, but the close relation between the temperature change and the mittelschmerz is of interest.

Discussion

Early workers who described the mittelschmerz were in difficulties in ascribing a cause to the pain. This was due primarily to the fact that ovulation was thought to be closely related temporally to the onset of menstruation. It is now known from both direct and indirect evidence that ovulation occurs at some moment in the middle of the cycle. Intermenstrual pain, like changes in hormone excretion in the urine, physical changes in the cervical mucus, electrical potential changes, and so on, is obviously an indication of some alteration in the reproductive tract, and may be accepted as further evidence that ovulation occurs in the middle of the cycle.

The cause of the pain is still obscure. It is abolished by ovariectomy, but is not affected by operations that interfere with nervous pathways from the uterus. Painful tubal contractions may, however, be a possible explanation.

If, as the evidence suggests, the pain is connected with ovarian changes, the immediate cause may be either the pressure of a distending follicle just before ovulation or the actual rupture of the follicle.

It seems probable that the pain gives a closer indication of the time of ovulation in those women who are aware of it than any other method. In view of the experience of McSweeney and Wood (1940) that 21 out of 134 women could identify some discomfort in the mid-cycle, careful questioning about the mittelschmerz of patients who attend fertility clinics would seem to be worth while. Cases have certainly been reported (Wharton and Henriksen, 1936) in which the pain had been severe enough to prevent intercourse and in which advice to disregard the pain was immediately followed by conception.

Summary

The cyclical occurrence of intermenstrual pain (mittelschmerz) has been followed for 4½ years in a married woman aged 28. The onset of the pain is closely correlated with changes in the waking oral temperature, and is taken to be a reliable index of ovulation.

SYNDROME OF DIAPHRAGMATIC HERNIA AND ANAEMIA

BY

A. D. CODOUNIS, M.D.

Associate Professor of Clinical Medicine, University of Athens;
Director of Medical Clinic III of the Red Cross Hospital,
Athens

No medical or surgical disease presents a clinical symptomatology so varied and unstable as that of congenital or acquired diaphragmatic hernia. Harrington (1945) studied 320 cases of oesophageal hiatus hernia and found that an average of three previous erroneous diagnoses had been made before the correct diagnosis was established. In order of frequency the most common erroneous diagnoses were: cholecystitis, cholelithiasis, gastric ulcer, secondary anaemia, duodenal ulcer, hyperacidity, cardiac disease, carcinoma of the cardia, stricture of the oesophagus, appendicitis, and intestinal obstruction. Chevallier and Danel (1944) reported that diaphragmatic hernia was commonly associated with anaemia.

Katsigras (1946) reviewed the published reports of 955 cases of oesophageal hiatus hernia and observed that anaemia was associated with the hernia in 80 cases, a proportion of 8.3%.

In my view (Codounis, 1946) diaphragmatic hernia can provoke the appearance of microcytic or hypochromic anaemia, or of macrocytic or hyperchromic anaemia. The personal case here described appears to be unique in medical literature. A severe anaemia persisted for 24 years, as did the diaphragmatic hernia. At first there was a microcytic anaemia and later macrocytic anaemia.

Case Record

J. A., a man of 60, had previously suffered from malaria and jaundice. He had three children in good health, two born after the beginning of the anaemia. His present illness started in April, 1922. After an emotional disturbance he had been feeling increasingly weak, tired, and anxious. His skin was pale and his eyes yellowish. These symptoms, with anorexia and loss of weight, became more serious, and he consulted Professor Schlesinger in Vienna, who diagnosed hypochromic anaemia and prescribed iron and a change of climate.

Phase of Microcytic Anaemia—After three months' rest at Semmering J. A. returned feeling better. In December, 1922, pallor and progressive weakness reappeared, with vomiting, nausea, and epigastric swelling after meals. In February, 1923, he went to Vienna to consult Dr. Eppinger, who diagnosed Banti's disease and advised splenectomy. X-ray examination of the gastro-intestinal tract revealed no abnormality—probably due to a technical defect.

J. A. later went to France, where the diagnosis of hypochromic anaemia was confirmed. After four months' rest in the country he came home in good health and noticed no symptoms during the year 1923.

In 1924, after the same clinical and haematological symptoms and some loss of weight (100 kg. to 82 kg.), he returned again to France and consulted Dr. P. E. Weill, who confirmed the diagnosis of hypochromic anaemia. The patient was given iron and liver extracts, which improved his condition. His red cell count fell to 3,000,000 per cmm in 1925, and Dr. Weill gave him a blood transfusion, after which the improvement was nearly complete. Between 1926 and 1938, during which twelve years he had iron therapy and a change of air each summer, the patient was free from symptoms and lost no more weight. His usual weight was 100 kg., which was considered normal in relation to his height.

After an attack of influenza in November, 1938, J. A. felt very weak and dizzy. There was marked pallor of the skin.

and mucous membranes, and a generalized oedema. Iron and liver extracts were prescribed and he was given three blood transfusions; the second provoked a severe anaphylactic shock, which was nearly fatal. Five days later the red cell count was only 900,000 per c.mm. Slowly the anaemia improved again; large doses of iron, 10 to 12 g. daily, were prescribed, but the patient could take only 4 to 5 g. daily.

He felt no pain between 1939 and 1941, but because of wartime food shortages he lost 25 to 30 kg. in weight.

In July, 1941, apart from weakness and pallor, J. A. complained of pains in the left upper abdomen and palpitations. Dr. Maroulis, a colleague who saw him during this period, noted besides the anaemia hyperresonance in the left chest. The same iron therapy was continued and the patient improved again over the next five years (October, 1945).

Altogether the evolution of the first phase of microcytic and hypochromic anaemia included three long periods in which the condition was absolutely quiescent; after the appearance or reappearance of symptoms improvement was brought about by treatment with iron, and the patient could live a normal life.

Phase of Macrocytic Anaemia.—Marked pallor and oedema reappeared in November, 1945, together with pain in the left upper abdomen radiating to the scapular and lumbar regions. A blood count showed: r.b.c., 4,120,000; w.b.c., 6,400; Hb, 70%; colour index, 0.85. His symptoms grew rapidly worse, however, and on Dec. 26, 1945, J. A. came under my care.

At that time his temperature was 38.4° C. (101.2° F.), pulse rate 80, and he had slight tachypnoea. His face was like that of a case of nephritis, oedematous and very pale. His lips were bloodless, he was very weak and, besides the puffiness of the face, there was marked oedema of legs and meteorism. He had a slight thoracic kyphosis. His chest was of the emphysematous type; the percussion note was tympanitic; rales were heard at both bases.

Blood pressure: 170/90 mm. Hg. X-ray examination of the chest and heart indicated no abnormality. Radiographs of the spine revealed changes in the third and fourth dorsal vertebrae, probably due to a healed spondylitis. Examination of the urine showed some white cells and some calcium oxalate crystals.

Final Diagnosis

With this history and the findings here tabulated it was easy to assume a relapse of the anaemia which had affected the patient for 24 years. But we were surprised to see that instead of a microcytic and hypochromic anaemia there was a macrocytic and hyperchromic anaemia. Then, Jan. 5, 1946, an x-ray examination by Dr. Xanthakis,

TABLE I.—Haematological Findings

Date	R B C End of Microcytic Phase	Hb %	Colour Index	W B C	Differential Count %			
					Poly- morphs	Lympho.	Eosino.	Mono.

9.4.46	1,030,000	17	0.82	18,400	—	—	—	—

A. Evidence of polychromasia, anisocytosis, poikilocytosis, and predominance of macrocytes—among them are oval and well-coloured macrocytes (Naegeli's megalocytes). No granular erythrocytes. Some white cells with globular nuclei.

B. Average anisocytosis and poikilocytosis and hypochromia. Predominance of macrocytes and among them some Naegeli's megalocytes. Some giant platelets.

C. Average hypochromia and anisocytosis and poikilocytosis. One acidophilic normoblast per 100 white cells.

D. Some polychromasia, slight anisocytosis and poikilocytosis.

E. Bleeding time, 3 minutes; coagulation time, 9 minutes; blood urea, 0.45%; 35,000 platelets.

TABLE II.—Bone-Marrow Picture

Monocytes	1	—	—
Lymphocytes	1	7	—
Ferrata cells	—	1	—
Platelets:			
Megakaryocytes	—	2	—

I.—Dec. 27, 1945. Mitosis chiefly among the basophilic erythroblasts and anisocytosis with predominance of Naegeli's macrocytes. Vacuoles in the protoplasm and in the cellular nuclei.

II.—Jan. 17, 1946. Normoblasts present with relatively few mature nuclei in comparison with the protoplasm. Mitosis. Rods of giant cells and a good number of cells with lobulated nuclei.

III.—Immediately after death on April 10, 1946. Majority of reticulocytes are of Ferrata type. Majority of nuclei of polychromatophilic erythroblasts are in mitosis. Macroblasts rarely found. Asynchronism in maturation. Immature megakaryocytes noted with basophilic protoplasm and without lobulation of the nucleus.

undertaken to exclude the possibility of gastric ulcer or cancer, explained clearly the anaemia and the digestive symptoms and thoracic pains.

Immediately after the patient had taken the barium meal a displacement to the right of the lower end of the oesophagus was observed. A large pocket of air in the herniated and distended stomach extended seven finger-breadths above the diaphragm. The stomach was elongated, and immediately below the diaphragm, on the lesser curvature, a diverticulum was noted. Another small diverticulum was observed in the descending part of the duodenum. Here then was a case of diaphragmatic hernia in a man who had been treated for anaemia for over twenty-four years. This is the fortieth case of this syndrome to be described in the literature and the first case to be observed in Greece up to April 16, 1945, when a preliminary communication was made to the Medical Society of Athens. Reviewing the long history of this case, it may be seen to fall into six successive stages.

Stage 1.—Apparently perfectly healthy until the age of 36.

Stage 2.—Onset of hypochromic anaemia, from 36 to 39 years of age. It is at this stage that J. A. complained of the first dyspeptic disturbances—post-prandial discomfort, epigastric fullness, and occasional vomiting. Over these four years improvement in the anaemia would be followed by recrudescence, followed again by rapid improvement.

Stage 3.—The twelve years from the age of 39 to 51 are characterized by almost normal good health.

Stage 4.—From the age of 52 to 54 there was a new and intense recrudescence of anaemia, following a severe attack of influenza in 1938. He lost 25 to 30 kg. in weight and his red cell count fell to 900,000 per c.mm. Later, on consulting the patient's wife, we were told that at this period she heard some gurgling in his stomach, even at some distance away from him. At the same time he complained of acute pains in the left hypochondrium, disappearing a few minutes after protracted belching. Physical examination at that time showed a pronounced hyperresonance of the left hemithorax.

Stage 5.—Quite well again from 55 to 60 years of age.

Stage 6.—The final stage lasted six months, and coincided with a hyperchromic and macrocytic anaemia.

In our opinion this hernia was congenital, favoured by the patient's kyphosis, and it progressively dilated through

the diaphragmatic hiatus over a period of 24 years and was responsible for provoking the alternating anaemic syndrome. Diagnosis in these cases is extremely difficult. Often a secondary anaemia due to cancer is suspected, but an x-ray examination reveals the diaphragmatic hernia instead of cancer. This was true with our case as with the cases of Welti and Mahoudeau (1948). The discovery of a diaphragmatic hernia must often lead to surgical intervention. In fact, according to Welti and Mahoudeau, the only effective cure is surgical. In addition, the results of operation prove that the diaphragmatic hernia is the cause of the anaemia, since the latter disappears after operation.

Cause of the Anaemia

To explain the mechanism of this anaemia, Anglo-Saxon authors have invoked repeated haemorrhages. But in our case, and in many others, analysis of the stools has not revealed the least evidence of melaena. Chevallier (1944) suggested that the anaemia might be due to atrophy of the gastric mucosa and gastric achylia. Chevallier could not determine this point in his case, and the same applied to J. A. We tried several times to withdraw gastric juice, but failed to do so because of the extreme nervousness of the patient. Nevertheless, it was possible to withdraw gastric juice from another patient of approximately the same age and with a diaphragmatic hernia. This showed a complete achylia, even after the caffeine test. This patient, in spite of his pronounced emaciation and severe illness, paradoxically does not show any anaemia. His red cell count was 4,200,000 per c.mm., with haemoglobin 100%.

It is the fact that a proportion of cases of diaphragmatic hernia show some degree of anaemia. In most cases this is a microcytic hypochromic anaemia responding as rapidly to iron therapy as to surgical treatment of hernia. Hyperchromic macrocytic anaemia is very rare in these cases. Only one case was mentioned by Cain and his collaborators (1939), with a colour index of 1.50 and a severe hyperchromic and aplastic anaemia. This hyperchromic macrocytic anaemia has nothing in common with Biermer's anaemia. The anisocytosis is not accompanied by megalocytosis but by normoblastosis and macrocytosis, although to-day, according to some authors, megalocytosis and macrocytosis are almost synonymous. This anaemia also presents a distinct resemblance to that of avitaminosis B₁₂ and to certain other primitive or secondary anaemias. In the case described by Cain liver therapy proved ineffective, whereas cure was effected by gastric extracts.

In the macrocytic stage in our patient liver extracts and small direct transfusions of fresh blood over 27 days raised the red cell count from 1,800,000 to 3,430,000 per c.mm. and notably improved the myelogram (see Table II). The improvement was remarkable, both clinically and haematologically.

In the 44 days following admission our patient received 350 ml. of fresh blood (by direct transfusions), 48 g. of iron, and 78 ml. of liver extract (by intramuscular injection). Clearly our patient needed not only anti-anaemic factor but also iron, owing to the presence of alternating microcytic and macrocytic anaemia.

Crisis and Death

After his discharge on March 6, 1946, with 4,180,000 red cells per c.mm., the patient remained well only until March 15.

He then began to feel slight pains in the left hemithorax and in the abdomen, which from time to time was distended. These pains were intermittent, and were relieved by belching. On March 30 the patient complained of

severe pains in the right and left chest. At the same time he presented pallor, anorexia, insomnia, and extreme asthenia.

On March 31 he was much worse and was readmitted. The radiologist's examination showed that the intrathoracic gastric pouch seemed more voluminous. There was also a gross distension of the ascending and transverse colon, displacing the liver to the left. We were obliged to assume that a sudden dilatation of the intrathoracic hernial pouch due to fermentative gases had provoked diaphragmatic spasms at the level of the oesophageal hiatus, which, by exciting the vagosympathetic system, affected in turn the abdominal segment of the stomach as also the small and large intestines.

These spasms, being repeated, disturbed the function of the digestive tract and respectively, by compression, the circulatory and respiratory functions. It is possible that this spasm contributes (by a mechanism which we have still not explained) to the production of putrefaction and fermentation (given the existence of an obstinate constipation), and so to the dysfunction of the haematopoietic system. In a case of this nature it may be that haemolytic factors discharged by the digestive tract into the circulatory system contribute to the production of this kind of anaemia. In any case, this last stage of severe anaemia was provoked from the second day by an intense hernial crisis simulating a strangulation. Once and only once we noted a positive Meyer's reaction in the faeces after an enema. There had been such obstinate constipation that we were obliged to extract the faeces digitally, and this probably caused small anal erosions which would explain this positive reaction.

We claim that this stage of the disease in our patient furnished indisputable proof that a diaphragmatic hernia can provoke an anaemia so severe that it may lead, with or without strangulation, to a fatal issue. On the eleventh day of this intense crisis J. A. died. We regret to say we could not proceed to necropsy owing to the objections of the relatives.

Conclusion

During the evolution of any form of diaphragmatic hernia different anaemic syndromes can occur. These ordinarily take the form of a microcytic or hypochromic anaemia—rarely the hyperchromic or macrocytic anaemia; and sometimes these syndromes alternate, as in our case.

In any case of anaemia in which the aetiology is not known a complete x-ray examination should not be omitted. This may reveal a diaphragmatic hernia. Conversely, whenever a diaphragmatic hernia is found we should not neglect a complete study of the patient's blood and bone marrow.

Summary

A case of diaphragmatic hernia is described in which a long-standing microcytic anaemia was succeeded by a severe and ultimately fatal macrocytic anaemia.

I am indebted to the Director of the laboratory of the Red Cross Hospital, Dr. S. Papageorgiou, for his help in the detailed study of the blood and the bone marrow.

The Ministry of Health has issued a circular drawing the attention of hospital management committees and boards of governors to the importance of close liaison with the resettlement services of the Ministry of Labour. During the war the Ministry of Labour set up a staff of disablement resettlement officers to give advice and assistance on the employment of disabled people who have difficulty in getting or keeping a job. In many cases the disability was mental or complicated by mental factors. This service will now be extended as widely as the mental health resources of the National Health Service permit. The Ministry hopes that psychiatrists and D.R.O.s will get into personal touch with each other and co-operate in working the scheme.

AMOEBIC VAGINITIS

BY

N. C. SEN, M.B., D.G.O., F.R.C.S. Ed.

Sanctoria Hospital, Burdwan, West Bengal

Amoebic vaginitis is rare. In a study of 200 cases of leucorrhoea Bickers (1943) observed that 0.5% were due to *Entamoeba histolytica*, but he did not report any case. Between 1916 and 1948 only fourteen cases have been recorded, notably by May (1943), Morse and Seaton (1943), Cleland (1944), de Rivas (1944), Weinstein and Weed (1948), and others. Most textbooks are silent about a condition which should receive more attention, particularly in the Tropics and subtropics, where the incidence of amoebic infestation is fairly high.

Case Report

A nulliparous Nepalese widow, aged 35, was seen in May, 1948. She complained of a profuse seropurulent vaginal discharge first noticed in January of that year. There was some soreness of the vulva and a slight burning sensation in the vagina and during micturition. The discharge was almost continuous, and there was no alteration in its character or amount before or after menstruation.

She had had a severe attack of dysentery, presumably amoebic, in December, 1947, when she was treated elsewhere and no specific remedy was administered. Soon afterwards she noticed swelling and pain in the perineum and the lower parts of both labia majora. The present symptoms followed and the discharge increased until she was forced to come to the hospital for treatment.

Pelvic examination had to be undertaken under general anaesthesia. The lower part of the right labium majus was slightly swollen. The fourchette presented a small ulcer in its right half. In the vagina there were many linear ulcers, lying mostly transversely in the furrows between the folds of mucosa. They were superficial, punched-out ulcers with slightly overhanging edges which bled easily. The bases were raw and red except for a few ulcers near the fornices covered with a thin yellowish slough. The cervix was slightly enlarged, soft, and ulcerated over the whole of its surface except for a small rim near the reflection of the vaginal mucosa on the portio. The external os could not be detected. The uterus was bulky, ft. and anteverted.

Examination of the thick seropurulent vaginal discharge, both dry and hanging-drop smears, disclosed many active forms of *E. histolytica*. The discharge was acid in reaction and presented a few pus cells, many eosinophils, red blood cells, and vaginal cells, with Gram-positive cocci and a few Gram-negative bacilli. Scrapings from the ulcers again revealed active *E. histolytica*. The discharge obtained by milking the urethra presented, both by dry and hanging-drop smears, active forms of *E. histolytica*. Biopsy of an ulcer showed evidence of subacute inflammation but no *E. histolytica*.

Examination of the stools revealed cysts of *E. histolytica*, but proctoscopy showed no ulcer in the lower anorectal canal. Other evidences of amoebiasis were the enlarged tender liver and slight tenderness and thickening of the descending and iliac colon. There were a few leucodermic patches in the region of the waist.

Treatment

Treatment with emetine hydrochloride was started. It was given in daily doses of 1 gr. (65 mg.) intramuscularly. The vagina was cleaned twice daily with warm normal saline douches. After five days the discharge and discomfort were much relieved and examination could be undertaken without anaesthesia. The ulcers were healed or healing. The cervical lesion looked smaller and the external os could be detected. The cervical discharge was aspirated and showed a few *E. histolytica* with very sluggish movement. They were almost round, and looked like the precystic forms of the parasite.

The patient was complaining of some vague hypogastric pain associated with frequent micturition. A catheter specimen

showed a number of entamoebae again moving sluggishly. No local treatment was given for this amoebic trigonitis or cystitis. Treatment with emetine was continued, and "stovarsol" vaginal compound was given every night after the saline douches. She was also given an alkaline mixture.

After 12 gr. (0.8 g.) of emetine in fifteen days the ulcers were completely healed and the patient felt perfectly well. No urinary symptoms remained, and examination of urine and vaginal discharge revealed no abnormality.

Discussion

Three points favour the diagnosis of amoebic vaginitis (1) Vegetative forms of *E. histolytica* in the discharges and scrapings from the ulcer. (2) Rapid cure with specific amoebicidal drugs. (3) The punched-out character of the ulcers, with slightly overhanging edges and sometimes yellowish bases, situated mostly in the furrows between the folds of the vaginal mucosa, which shows very little inflammatory reaction.

Infection of the vagina is presumably by continuity and contiguity with the anorectal canal, and this may be helped mechanically by the method of ablation practised in Bengal to cleanse the part after defaecation.

The cervix is involved in about 70% of the reported cases, and the ulcer is usually placed eccentrically and away from the external os. The uterus is often enlarged, and it may be that many or all of the cases in which the uterus is enlarged, soft, and tender have some infection of the uterus. Uterine aspiration was not done in any of the reported cases.

Leucorrhoea due to *E. histolytica* may be fairly common in India. Cases should be investigated thoroughly from this point of view.

Medical Memoranda

Perforation of Stomach in Scrotal Hernia

Owing to the rarity of this condition (only one other case of this type occurs in the literature: Jayle, 1893) I feel that the following is worthy of record.

CASE REPORT

The patient, a man aged 66, was sent into hospital for ? strangulated left inguinal hernia. He had had a left inguinal hernia for 35 years. Two months previous to his admission he had undergone prostatectomy here, with an uneventful recovery. At the time it was noticed that he had a small left inguinal hernia; since the operation he had been perfectly well. Twenty-four hours before admission the hernia had descended into the scrotal sac, and one hour before admission the patient experienced a sudden severe pain over the left inguinal region, accompanied by nausea and vomiting, the vomitus being gastric contents. The pain was continuous; he was crying out in agony, and disliked being moved. His last bowel motion had been twelve hours before admission, and he had passed urine that day.

Examination showed a well-covered muscular man. His general condition was reasonably good, but he was dehydrated. Temperature 96.4° F. (35.8° C.); pulse 126; respirations 44. He had a large scrotal swelling 12.5 cm. in diameter, which filled the whole of the scrotum. The scrotum was tender, but not excessively so, and was resonant on percussion. The patient complained of severe pain and tenderness over the region of the external inguinal ring. There was some slight abdominal rigidity. Peristaltic sounds were heard and the abdomen was generally resonant. The tongue was furred and dry, and the lungs and heart were normal. A diagnosis of strangulated left inguinal hernia was made, and the patient was given ½ gr. (16 mg.) of morphine, was put on a glucose-saline drip, and was prepared for the theatre.

Operation.—This was done by Mr. Ganz (anaesthetic: thiopentone, cyclopropane, and curare, administered by Dr. Waters). A T-shaped incision was made over the left inguinal region—the horizontal part of the incision parallel to the inguinal ligament and the vertical part over the scrotum. The coverings of the hernia were separated and the peritoneum was opened. Fragments of yellowish inspissated material and about 4 oz. (56 g.) of golden-coloured fluid were present in the scrotal sac. The bowel was delivered from the scrotum and found to consist of a portion of the stomach, some coils of small intestine, the transverse and pelvic colons, also the descending colon, which was provided with a mesentery. There were also small pieces of food in the scrotal sac. The bowel was returned to the abdominal cavity and the skin incision prolonged upwards; a large perforation 5 cm. by 5 cm. was found on the lesser curve of the stomach. The adjacent stomach wall was extremely thin. The perforation was sutured and oversewn with a double layer of stitches and an omental graft. The wound was closed and nylon skin sutures were inserted. On the return of the patient from the theatre he was given penicillin, sulphathiazole, and continuous oxygen, but his condition deteriorated and he died the following day.

Necropsy.—The abdomen was moderately distended. On opening the peritoneum a purulent acute generalized peritonitis was found, with much pus under the right lobe of the liver and in the right paracolic gutter. Inspissated yellowish-brown faecal-looking lumps of material were scattered all over the peritoneal cavity. A large hernial sac was occupied by loops of both small and large bowel and a number of similar lumps of material as mentioned above. The orifice of the sac was three fingerbreadths and was surrounded by a firm fibrous ring. The stomach was exceedingly mobile and elongated, with a scarcely definable lesser omentum. A piece of greater omentum was sutured over and partly closed a long oval hole (8 cm.) about the centre of the lesser curve. This perforation was through a blackened gangrenous area of stomach wall, and gastric contents had exuded into the peritoneal cavity and lesser sac. Obviously necrotic stomach wall extended 4 cm. around the perforation. There was no evidence of a chronic peptic ulcer. A few small thrombosed veins were present in the affected stomach wall, but no other vascular occlusion could be found. The right and left gastric arteries were normal. No pressure ring could be discerned to suggest the site of strangulation.

Examination of the C.V.S. failed to show any source of embolism. The pathologist's comment was: "It appears that this was a Richter's hernia in which the stomach was strangulated followed by perforation."

COMMENT

The probable course of events was that a portion of the large bowel had entered the hernial sac, this being rendered easy by its mobile mesentery; the stomach had been dragged into the sac by the gastrocolic omentum, and the lesser curve had been strangulated at the neck of the sac, with subsequent perforation of the stomach wall. Though the perforation was sealed at operation it is apparent that a further area of stomach wall had necrosed and subsequently perforated, resulting in the death of the patient.

My thanks are due to Mr. J. B. Marinan, medical superintendent, for his permission to publish this case and for his interest and helpful suggestions, and to Dr. J. Ennis for his post-mortem report.

A "Third Ureter" in Prostatectomy

Despite the sanguine views of many of my surgical confrères regarding the control of haemorrhage in the various forms of prostatectomy with bladder closure, I am dissatisfied in this respect. While not unmindful of the wholesome effects of the closed bladder after prostatectomy, sisters and house-surgeons have come to regard it with no little concern and even apprehension because of reactionary bleeding and clots lodging in the urethral drain, with distressing results. One finishes the operation with a gratifying degree of haemostasis, yet a day or two later one too often meets with disquieting reports of catheter difficulties, and evidently the staff have been somewhat anxious and harassed. The patient shares in the agitation instead of resting quietly after his ordeal. For his comfort and safe healing, and for the contentment of the surgical team, something more is needed in post-operative technique.

Catheter drainage depends on two factors—paucity of blood and plenitude of urine delivered by the ureters. Unfortunately,

owing to the shock of operation and the subnormal intake of fluids, the kidney action is all too often in abeyance. Accordingly I have tackled the problem from this direction. Since we cannot rely on adequate repression of bleeding, the logical remedy is to compensate for surgical oliguria by artificial "diuresis," using a rubber tube drip of dilute antiseptic from a bedside reservoir. This "third ureter" pleases everyone, including the patient, who prefers an automaton to intermittent service by nurses punctuating his repose for a day or so after operation and sometimes resorting to regrettably forceful syringing and sucking to clear his clogged drain.

The technique is not intended to cover slackness in surgical haemostasis but to confer on residents and nurses a feeling of calm confidence instead of anxiety that taxes their energies unduly during aftercare. I use the procedure after all three operations (Harris, Hey, or Millin), and even after resectomy occasionally insert a small suprapubic drain. As "third ureter" I employ a Jacques (No. 4) catheter, the orifice of which rests on the base of the bladder.

METHOD

A small Lister bougie is introduced (via the bladder-neck in Millin's operation) and pressed up against the dome of the bladder, which is incised for the tip to protrude. On this I slide the catheter by its open end after having cut off the tip. The sound is withdrawn with the catheter into the bladder and then detached. A stitch tethers the catheter to the skin, and anchorage is reinforced by "elastoplast" to prevent its being dragged out by inadvertent pulls. A glass connexion joins the outer end with light rubber tubing, which is interrupted by a glass drip on its way to a douche-can of irrigating fluid on a stand by the patient's bedside. The urethral catheter (24E) draining the bladder is suspended by a single nylon

Photograph showing the "third ureter" on the day after Millin's prostatectomy.

thread which pierces the bladder and abdominal walls about 1 in. (2.5 cm.) from the midline and is tied to a Harris metal rod. The outer end of this urethral drain is joined to a rubber tube of about the same calibre and not too readily compressible (see Figure), which ends a foot from the bottom of the bucket. Irrigation is set going at about 50 drops a minute for the first few hours, and the speed is adjusted by a screw-clamp to the safe degree of dilution. To dispel doubts arising about a clear channel, release the clamp and flush through the system.

The constancy of the irrigation is assured not only by the staff's seeing the issuing drip, but the patient or the nurse, even in the dark, can also tell by the friendly sound of the drops. This continues for about 48 hours, by which time the water is generally a pale red hue or clear. The vital injunction to the nurse is, "Never leave the drip running in unless there is a corresponding outflow." The procedure can continue with the patient sitting out of bed, or it may be interrupted while he moves about. The "third ureter" is removed on the third or fourth day. Subsequent leakage is absent or negligible.

Reviews

STATE MEDICINE IN THE U.S.A.

Voluntary Medical Care Insurance in the United States. By Franz Goldmann, M.D. (Pp. 228, 16s.) New York: Columbia University Press. London: Geoffrey Cumberlege. 1948.

All the signs point to the early provision of some form of national health insurance in the U.S.A. There is a voluminous literature on the subject, and Dr. Goldmann has added to it a useful objective examination of how far voluntary schemes have provided, or failed to provide, medical care for the community. Every writer on the topic agrees that the usual system of payment per service rendered fails to meet the needs and financial capacity of a considerable section of the community. The organized medical profession, while admitting this, has claimed that the problem would be manageable by a voluntary system of prepayment.

This book shows that efforts to achieve such a solution have been numerous. Some have been sponsored by commercial insurance companies, some by combinations of employers and employees, some by organized groups of doctors. The majority of the schemes provide only for hospital cases. At the end of 1946 over twenty-four million persons were enrolled in hospital service schemes, as against some five million in schemes providing home and general treatment. Dr. Goldmann says that many practitioners view with apprehension the popularity of the hospital schemes, which could, and sometimes do, favour practice from as well as in the hospitals. The author comes to the conclusion that so far as plans for general medical care are concerned "the lower income groups are not reached to any considerable extent," and that most of these schemes are "far from comprehensive in the benefits they offer." The difficulty with all these projects is that of attracting, and retaining, the more favourable risks. In order to remain solvent the sponsors must restrict either the freedom to join or the scope of the service. The low premiums within the reach of the poorer classes yield funds which will not allow of a complete service. The author is of opinion that the group practice schemes have been the most successful from the point of view of scope of service. The objections of the medical profession and others to compulsory insurance are stated and appreciated, but one is left with the impression that Dr. Goldmann is driven to the conclusion that no complete system of medical care can be brought within the reach of a considerable section of the population without the help of the State. The question now to be debated is, How much help, and in what form?

ALFRED COX.

MALARIA IN AFRICA

Malaria. With Special Reference to the African Forms. By W. K. Blackie, M.D., Ph.D., F.R.C.P.Ed., D.T.M.&H. (Pp. 104, 10s. 6d.) Capetown "The African Bookman." P.O. Box 3115.

Malaria Control by Coastal Swamp Drainage in West Africa. By A. B. Gilroy, O.B.E., M.B., B.S.(Melb.), D.T.M.&H.(Eng.). (Pp. 97; 22 plates. No price.) London: Ross Institute of Tropical Medicine.

If in the past Africa has had a reputation for backwardness this should not apply to the future. For if Africa could be rid of, as now seems possible, of malaria and tsetse fly it promises to play in the future a large part in the economic affairs of the world. These two small books are indicative of the interest now taken in Africa in the control of the first of these adverse conditions. Dr. Blackie gives a good short description of malaria. It is likely to be useful to the practising medical man as providing an up-to-date account of modern antimalarial treatment; though the reviewer would have thought it better to refer to the intramuscular administration of quinine only as a form of treatment that need never now be used, since, if intramuscular injection must be given, mepacrine is preferable.

The second work is more unusual. Dr. Gilroy gives an account of malaria control operations carried out since 1942 at Lagos. Lagos is a town originally crowded on to a small

sandy estuarine island, but with its increasing population and importance it has lately extended on to the only land available—low-lying tidal swamp, much of it mangrove. Fortunately recent research on malaria under these conditions has been helpful, and the study of the mangrove and of the special habits of the species of anopheles concerned in transmission has given a clear indication of the kind of measures to be adopted. The description given of the natural history of the different kinds of mangrove, the kinds of swamp they give rise to, and the relation of these to the tides and the breeding places of anopheles makes interesting reading, as also do the very clear accounts of the different operations undertaken. The book is enlivened with some clever sketches of operations in progress and with photographs giving the different types of swamp and the nature of the engineering work carried out.

S. R. CHRISTOPHERS.

PRACTICAL GUIDE TO LEPROSY

Manual of Leprosy. By Ernest Muir, C.M.G., C.I.E., M.D., F.R.C.S.Ed. (Pp. 208; 70 illustrations, several in colour. 17s. 6d.) Edinburgh: E. and S. Livingstone. 1948.

This small book has been written for the guidance of doctors, nurses, and lay workers who undertake leprosy work. For this reason the author discusses mainly clinical features, treatment, and the methods of prevention in common use, and devotes little space to history, prevalence, and epidemiology. His account of the histology and the reaction of the tissues to the infection is good and illustrated by sections—some in colour—showing the tissue changes and the causative bacilli. He has adopted the recent South American classification based on histological changes instead of the clinical one of the Cairo Conference. The former is the more scientific, but it will prove to be rather confusing to the large proportion of field workers who have neither time nor facilities for making such examinations.

The clinical chapters are the most detailed and useful part of the book, and they are illustrated by photographs taken by the author. He records the treatment that he has long used, but omits to mention some preparations that other authorities have given with advantage. Dr. Muir advises injections of hydnocarpic oil intradermally and into the deeper tissues; he also mentions the use of the ethyl esters, which are generally relied on by American workers but are more expensive. He differs from some authorities in recommending intermissions in the courses of injections. He advises sulphone treatment in lepromatous cases and also suggests that it be tried in the "uncharacteristic" type with negative lepromin reactions. Recent trials of sulphethrone indicate that it is less toxic than other forms, but it is still too early to decide on the precise value of this new line of treatment. The concluding section of the book is a practical account of the methods now in general use for the control of leprosy. He advocates compulsory segregation in endemic areas when accommodation is available, and also discusses home isolation. He recommends the examination of school-children and gives much good advice. This book embodies great practical experience and will be of value to those for whom it is intended.

LEONARD ROGERS.

ESSAYS IN PSYCHIATRY

The Yearbook of Psychoanalysis. Edited by S. Lorand, M.D., and others. Volume 3, 1947. (Pp. 308. £1 10s.) London: Imago Publishing Company. 1948.

The third volume of this series maintains the standards set by the first two. It is to be regretted that the publishers persist in describing it as a compendium of recent advances in the theory and practice of psycho-analysis. Although it contains few research contributions of value, it is certainly an interesting collection of essays on a wide range of subjects from a correlation of the basic ideas common to Freud and to Spinoza (Bernard, New York) to such curious matters as the charming away of sties by means of barley and wedding-ring rituals (Inman, London). Of the clinical papers the most outstanding are those by Garma (Buenos Aires) and by Jacobson (New York) on various aspects of melancholia and on the effect of disappointment on depressive development.

d one by Schonberger (Budapest) on the nightmare syndrome. summary by W. C. Menninger (Topeka) of modern concepts of war neurosis is notable mainly as demonstrating the absence of any significant advances in this field despite the opportunities afforded by the second world war.

Although yearbooks of this sort usually command considerable technical understanding on the part of the reader, this particular issue contains a number of papers of more general interest, in particular Ernest Jones's valedictory address and

D. Adrian's lecture on the mental and physical origins of behaviour. A number of articles on applied psycho-analysis, among others, Wittels (New York), Marie Bonaparte (Paris), and the late Hanns Sachs provide additional attractions for the non-analytical reader.

Excellent as it is, the volume would have been greatly improved by the omission of several rather platitudinous short pieces and of a longish but very superficial and unilluminating study on the anti-Semitic character.

EDWARD GLOVER.

MENTAL DEFICIENCY

A Textbook of Mental Deficiency (Amentia). By A. F. Tredgold, M.D., F.R.C.P., F.R.S.E. Seventh edition (Pp. 534; 47 plates 30s.) London: Baillière, Tindall and Cox 1947.

For forty years Dr. Tredgold's scholarly textbook on mental deficiency has held a unique position. A medical subject which is tended to be neglected in the writings of neurological and psychiatric specialists receives attention here in a manner particularly well adapted to the needs of both clinicians and administrators. In the new edition the original illustrations—many of them wisely chosen from Dr. Brushfield's and Dr. Turner's case photographs—have been supplemented by other excellent pictures. New features include notes on amentia due to Rh incompatibility and on the Laurence-Moon-Biedl and Rud syndromes, but the discussions on pre-natal infections have not been expanded. The author provides copious information on legal and administrative problems and is brought it up to date by including an account of the effects of the Education Act of 1944.

Readers will be glad to find that the attractive discussions on isolation amentia and idiot savants still hold their places in the book. The only disappointment is that the classification of the clinical varieties of amentia summarized on p. 65 is substantially unaltered. The grouping is not easy to justify in the light of modern genetical thinking, though it is admittedly difficult to find any really logical method of classification. Dr. Tredgold's lucid style of writing makes the book a pleasure to read. This is most fortunate in a textbook which it is essential for all serious students of the subject to master, whether or not they agree with all the views expressed.

L. S. PENROSE.

HOSPITAL MANAGEMENT

On Hospitals. By S. S. Goldwater, M.D. (Pp. 395, illustrated 59.00 or 45s.) New York and London: The Macmillan Company 1947.

Dr. S. S. Goldwater, who died in 1942, had a distinguished career as a health-service and hospital administrator, having been Superintendent and Director of the Mount Sinai Hospital, New York, Commissioner of Health of the City of New York, and Consultant in Hospital Organizations and Planning. This book is a collection of the essays, papers, and reports written by him during his long career, together with plans of many of the hospitals for which he was responsible.

He discusses the whole range of hospital management and construction, and every word is inspired by his obvious devotion to the cause he had at heart. Most of his ideas were far ahead of his time, but very few have not now been accepted; those concerned with the social aspects of hospital administration are especially in point and most of them are now implicit in all our thinking. While many of the essays are lucid expositions of the whole philosophy underlying provision of care for the sick, the author never loses sight of the material aspects. His influence on the development of community health care and on the planning of hospitals was probably greater than that of any other man of his time.

ANDREW TOPPING

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

New and Nonofficial Remedies, 1948. (Pp. 800 21s.) London: J. B. Lippincott. 1948.

Issued by the Council on Pharmacy and Chemistry of the American Medical Association.

Pediatrics and the Emotional Needs of the Child. Edited by H. L. Witmer. (Pp. 180 8s 6d.) London: Geoffrey Cumberlege 1948.

Papers read at a joint discussion by American paediatricians and psychiatrists.

The Biology of Bacteria. By A. T. Henrici, M.D. 3rd ed. (Pp. 577. 25s.) London: George G. Harrap 1948.

An introduction to general microbiology.

The Management of Binocular Imbalance. By E. Krnisky, M.D. (Pp. 464. 63s.) London: Henry Kimpton 1948.

From the New York Polyclinic Medical School.

Primary Anatomy. By H. A. Cates, M.B. (Pp. 478 33s.) London: Baillière, Tindall and Cox. 1948.

For nurses, physiotherapists, and others of similar interests.

Psychiatry. By H. C. Beccle, M.B., M.R.C.P., D.P.M. (Pp. 245. 17s 6d.) London: Faber and Faber 1949.

Theory and practice for nurses and students.

Surgical Pathology. By P. A. Herbut, M.D. (Pp. 710 60s.) London: Henry Kimpton 1948.

A new American work.

The Plant Alkaloids. By T. A. Henry, D.Sc. 4th ed. (Pp. 804 63s.) London: J. and A. Churchill 1949.

The new edition is largely rewritten.

Kayne, Pagel, and O'Shaughnessy's Pulmonary Tuberculosis. Revised by W. Pagel, F.F.D., and others. 2nd ed. (Pp. 720 67s.) London: Geoffrey Cumberlege. 1948.

An extensively revised edition.

The Third Mental Measurements Yearbook. Edited by O. K. Buros. (Pp. 1,246 \$12.50.) New Brunswick: Rutgers University Press 1949.

A guide to recent work.

Penicillin and Other Antibiotics. By G. W. S. Andrews, M.B., B.S., and J. Miller, B.Sc. (Pp. 160 7s 6d.) London: Todd Publishing Group 1949.

A short survey of antibiotics.

Science in Liberated Europe. By J. G. Crowther. (Pp. 226 18s.) London: Pilot Press 1949.

An account of the activities of European scientists before and after liberation.

Medical and Nursing Dictionary and Encyclopaedia. By E. Pearce. 9th ed. (Pp. 723 17s 6d.) London: Faber and Faber 1949.

A further edition of the well-known dictionary for nurses.

Polio and its Problems. By R. H. Berg. (Pp. 174 18s.) London: J. B. Lippincott. 1948.

A popular account of poliomyelitis.

Widening Horizons in Medical Education. A Report of the Joint Committee of the Associated American Medical Colleges and the American Association of Medical Social Workers. (Pp. 228 15s.) London: Geoffrey Cumberlege 1948.

A study of the teaching of social and environmental factors in medicine.

The Situation in Biological Science. (Pp. 631 9s 6d.) London: Collet's Holdings 1949.

SATURDAY MAY 7 1949

A NEW TREATMENT FOR RHEUMATOID ARTHRITIS

Rheumatoid arthritis is known to have existed in prehistoric times, and the search for a cure has presumably continued ever since. In the course of time much information has accumulated about the natural history, pathology, and the provocative factors of the disease, but since the waning of belief in an all-important infective factor little certain information exists about its aetiology. In his recent Oration before the Heberden Society in London, Dr. P. S. Hench¹ reiterated the known facts and pointed out that rheumatoid arthritis has two sharply contrasting characteristics—that of potential chronicity and that of potential reversibility. He divided the causes of reversibility into spontaneous, therapeutic, and accidental. Spontaneous remissions have always been recognized as a possible occurrence even in cases in which the prognosis seems hopeless²; therapeutic remissions can be induced in a proportion of cases by means of gold therapy or blood transfusion; whilst accidental remission may frequently occur in pregnancy and in jaundice of certain types.

Consideration of these facts makes it increasingly difficult to harmonize the microbic theory of the origin of rheumatoid arthritis with modern knowledge. It seems more probable that the disease is part of a basal biochemical disturbance of unknown type which is accidentally and transiently corrected by some biological change common to a number of apparently unrelated conditions—pregnancy and jaundice being the most notable. Hoping to reproduce the beneficial effects of pregnancy, physicians have administered fairly large doses of female hormones to non-pregnant sufferers from rheumatoid arthritis, but the results have mostly proved to be disappointing, as has the employment of transfusions of blood from pregnant women—a form of therapy which was recently advocated³.

Last year workers at the Mayo Clinic put forward the conjecture that the anti-rheumatic factor might prove to be one of the adrenal hormones. Recent work by Selye^{4,5} and others on the biochemical changes induced in animals exposed to a wide variety of noxious agents has shown that the changes vary with the intensity and the duration of the stress but are independent of its nature. This has been termed the "general adaptation syndrome," and has been shown to be due to excessive secretion by the anterior

pituitary gland of corticotropin, which in turn stimulates increased adrenocortical secretion. Continued application of the stress is accompanied by continued hyperactivity of the hypophysis-adrenal mechanism, and for a time there is high resistance to the particular agent used and increased susceptibility to all others. Ultimately all resistance breaks down when the adaptive energy is exhausted.

Interest in this syndrome was aroused when Selye pointed out that it lent itself to a concept of "adaptation diseases." By various experimental procedures he produced in animals changes in the joints and the heart similar to those observed in human rheumatism, and concluded that "the adrenal cortex may play an important role in the pathogenesis of rheumatic and rheumatoid conditions in man."⁶ Further experiments have shown that the essential requirement to enable these and other pathological changes to be brought about is an excess of salt-active corticoid hormone. This would suggest that during the phase of resistance the increased corticoids, which are normally beneficial, are capable in certain circumstances of producing recognized disease syndromes. Knowlton,⁷ searching for the modifying factors which in most cases presumably prevent the effect of stress resulting in "adaptation" disease, suggests that such disease is the result of a dual mechanism, the one factor being the non-specific effect of corticoids and the other a property specific for the given stress and the determinant of the site of the effect.

In September, 1948, Kendall was able to provide for Hench and his colleagues at the Mayo Clinic a supply of 17-hydroxy-11-dehydrocorticosterone (compound E) for clinical trial.⁸ This was administered to a female patient, aged 29, who had had severe rheumatoid arthritis for 4½ years. She had not responded satisfactorily to any method of treatment, and many joints were swollen, stiff, and very painful on any movement. Radiographs disclosed severe destructive changes in her right hip and less severe lesions in other joints. The blood sedimentation rate was 108 mm (Westergren), and the patient's condition appeared to be deteriorating. On Sept. 20, 1948, she could hardly get out of bed, and on that day intramuscular injections of compound E were started in daily doses of 100 mg. No change was noted until Sept. 30, when she rolled over in bed for the first time with ease and reported much less muscular stiffness and pain. On the next morning all muscular stiffness had left her, her appetite returned, and she was able to walk with only a slight limp. By the seventh day of treatment all tenderness and pain on movement and even swellings were greatly lessened. The next day she went out shopping for three hours, returning tired but with no stiffness or pain. The progress made by this patient was for various reasons not fully maintained, but since then a total of 14 other cases have been treated, in all of which considerable and rapid improvement has been noted. Since January, 1949, compound E acetate, a more easily prepared and less expensive product, has been used in place of compound E, with equally good results.

Two female patients with severe rheumatoid arthritis were also treated with 100 mg. of pituitary adrenocorticotrophic hormone (ACTH) intramuscularly for 12 days. The results of metabolic studies on these patients have yet to be published, but it is reported that clinical improvement

¹ *Ann. N.Y. Acad. Sci.* 1949, 4, 1-15.

³ *Brit. J. Rheumatism* 1947, 2, 252.
⁴ *J. Clin. Endocrinol.* 1946, 6, 117.
⁵ *J. Clin. Endocrinol.* 1948, 8, 433.
⁶ *J. Amer. med. Ass.* 1944, 124, 201.
⁷ *Lancet* 1948, 1, 315.
⁸ *J. Clin. Endocrinol.* 1949, 9, 181.

similar to that resulting from the use of compound E occurred promptly in both.

The number of patients so far treated by this new method is small. This is due principally to shortage of supplies of the hormone; great efforts have been made to overcome this, but the technique of preparation is difficult, time-consuming, and expensive. As a control experiment the injections of compound E were at times, unknown both to the patient and the administrator, replaced by an inactive solution. When this was done articular and muscular symptoms recurred within a few days, and the sedimentation rate rose in every case. No serious toxic reactions have been noted as the result of administration of compound E or its acetate, with the exception of transient oedema. Nevertheless much more experience is needed before sufficient knowledge will be acquired about its efficacy and safety with prolonged administration.

The effects of related compounds such as dehydrocorticosterone (compound A), 17-hydroxycorticosterone (compound F), desoxycorticosterone (DCA), and pituitary adrenocorticotrophic hormone (ACTH) are being investigated by Hench and his colleagues. Some years prior to the recent war a small-scale trial of the effect of desoxycorticosterone on rheumatoid arthritis was carried out by the Empire Rheumatism Council in this country, with negative results, but, so far as is known, none of the other compounds mentioned have yet been applied to the treatment of the rheumatic group of diseases.

It would appear from the information so far available that a therapeutic discovery of the greatest importance has been made. It is of course unfortunate that the amounts available of both compound E and of the adrenocorticotrophic hormone are so small, and are likely to remain so until these substances can be synthesized. However, arrangements are in hand for a thorough trial in this country when supplies are adequate.

ESSENTIAL HYPERTENSION

Since Sir Clifford Allbutt¹ first recognized 50 years ago that arterial hypertension sometimes arises in the absence of renal disease research into what is now called essential hypertension has gained such impetus, especially during the last decade, that it has become a difficult task for the clinician to keep in touch with the rapid advances being made, and still more difficult for him to correlate their significance. Clamping of the renal arteries in animals seems far removed from non-renal hypertension in man, and the recognized influence of heredity is at first glance a paradox, since there is a growing impression, recently referred to in this *Journal* by Ogilvie,² that hypertension is a stress disease. It is not even clear whether it is a single disease or a symptom complex. The lectures given by Professor F. H. Smirk at the British Postgraduate Medical School and reported elsewhere in this issue of the *Journal* are therefore welcome, since they help to put the many current problems of essential hypertension in clear perspective.

It is generally accepted that the raised blood pressure in essential hypertension frequently precedes pathological changes in the arterioles, and that sustained hypertension causes or accelerates the development of arteriosclerosis. It follows that renal ischaemia due to vascular changes cannot be the initial factor in the production of essential hypertension in young subjects. In later life, however, pathological changes in the renal arterioles are always present. Essential hypertension arising after the age of 45 may possibly be secondary to these changes, and it is conceivable that the disease in youth is aetiologically distinct from that arising after middle age. It is fundamental to the understanding of essential hypertension to realize that an increase in the blood pressure due to any cause, physiological or pathological, may be followed by a further increase, this secondary hypertension often persisting after the primary cause has ceased to operate. The mechanism by which the secondary rise in blood pressure is brought about is not clearly understood. Arteriosclerotic changes in the large vessels are not the cause, for they increase only the systolic pressure; and Volhard's theory that pathological narrowing of the arterioles causes increased peripheral resistance has now been disproved. It is known that ischaemic kidneys liberate renin, a pepsin-like enzyme; this is activated by a substrate (pre-angiotonin) found in normal serum to form a polypeptide, angiotonin, which causes vasoconstriction. Thus any stimulus producing vasoconstriction, and therefore renal ischaemia, will lead to angiotonin formation, further vasoconstriction, and an additional rise in the blood pressure.

The stimuli capable of starting this vicious circle may be functional rather than pathological, and the possible role of the renal shunt demonstrated by Trueta and others³ is plain. Another important factor is that the enlarged arterioles in hypertension respond excessively to vasoconstricting stimuli, so that once medial hypertrophy has taken place vasoconstriction is more readily maintained. The relative importance of these two factors is difficult to assess, but the variable response of different experimental animals subjected to the Goldblatt clamp serves as a warning against the unreserved acceptance of this mechanism in man. The persistence of hypertension after the cessation of the primary stimulus is usually attributed to renal arteriosclerosis, which develops during the period of primary hypertension. However, a non-renal mechanism is also possible, as shown by the persistent raised blood pressure in rats after bilateral nephrectomy.

Though the exact nature of these complicated mechanisms may not be clear, the implications are plain: any stimulus producing vasoconstriction will in time lead to permanent hypertension, and essential hypertension may arise either from exposure to excessive stimulation or from exaggerated vascular response to normal stimuli. The basic causes of hypertension are therefore to be sought in undue stress or in individual diathesis. The hypertensive diathesis can often be demonstrated clinically by an abnormal rise in the blood pressure following immersion of the arm in ice-cold water—subjects showing a positive response to this test being more liable to develop hypertension than those who respond normally. It is well known that the incidence of essential hypertension is higher

³ *Studies of the Renal Circulation*, 1947, Oxford.

⁴ *Quart. J. Med.*, 1947, 10, 111.

⁵ *Hypertension and Nephritis*, 1939, Philadelphia.

in some races than in others, and Platt⁴ has recently shown that hypertension is largely a hereditary disease, being transmitted as a Mendelian dominant. But stress factors are equally important; for example, African negroes lose their immunity to hypertension when living in the environment of Western civilization. The link between obesity and hypertension is not purely genetic: the obese hypertensive patient may become thin and normotensive through dieting alone—a fact sometimes overlooked in the treatment of the obese middle-aged patient with hypertension. Response of the blood pressure to emotion and mental effort varies greatly, but it has been shown that those who react to such stimuli with the greatest rises of blood pressure are more liable than others to develop permanent hypertension in later years.

Malignant hypertension is regarded by most authorities as a form of essential hypertension with a great increase of the diastolic pressure and acute arteriolar necrosis, and Fishberg⁵ prefers to call it the malignant phase of essential hypertension. Professor Smirk does not accept this concept as proved. He points out that malignant hypertension is rare in the province of Otago, New Zealand, and so also is chronic glomerulonephritis. He suggests that the two diseases may have some aetiological factor in common. Whatever may be the outcome of further studies on this possible relationship, the suggestion is in keeping with the theme of Professor Smirk's hypothesis: essential hypertension is not a single disease but a clinical state arising as the end-result of numerous primary causes. The cause may be physiological, as in environmental or emotional stress, or pathological, as in renal and endocrine disorders. The disease perhaps arises for different reasons in old age and in youth, and it may well be that malignant hypertension has a different primary cause. This wider concept of the disease should lead to further investigations of the factors in everyday life which are responsible for essential hypertension ranking so high in the diseases of civilization.

STILBOESTROL THERAPY IN PREGNANCY

Another contribution to the study of gynaecological and obstetrical endocrinology comes from O. W. Smith,¹ who now describes the results of four years' clinical and laboratory research on the action of diethylstilboestrol in pregnancy. Having persuaded clinicians in various parts of the U.S.A. to join in the work she is in a position to assess the value of giving stilboestrol as a routine from the results obtained in 632 pregnancies. The theoretical basis of the investigation lies in the claim by O. W. Smith and G. V. Smith² to have shown that oestrogens increase production of progesterone in non-pregnant women by stimulating the pituitary and in pregnant women by bringing about better "utilization of chorionic gonadotropin." In this respect diethylstilboestrol is held to be superior to the naturally occurring oestrogens because its action is not depressed

by progesterone already in circulation. O. W. Smith postulated that stilboestrol should be beneficial in pregnancy not by virtue of its own oestrogenic properties but by stimulating the placenta to secrete both oestrogen and progesterone. She therefore administered stilboestrol in cases of threatened and habitual abortion in "physiological" dosage, calculated according to the period of gestation. The results were good. Of 127 patients who had had at least two previous consecutive abortions, 102 (80%) were still pregnant after 28 weeks and 98 (77%) bore living babies; while of 38 women who had had three successive abortions 33 produced living children.

These are higher figures than the rates for spontaneous cure calculated by Malpas³ and Eastman⁴ in similar series of cases. Moreover, there was no evidence that the hormone treatment of threatened and habitual abortion increased the incidence of viable malformed foetuses. Vaux and Rakoff⁵ had previously reported good results with combined oestrogen and progesterone therapy in habitual abortion, as also had White⁶ in pregnant diabetic women. These writers regarded their form of treatment as substitution therapy, whereas Smith looked upon hers as stimulative—which should give better results, since the secreted hormones are likely to be supplied at a more uniform rate and in closer conformity to physiological needs. Many of Smith's patients received small daily doses of stilboestrol during the cycle of conception in order to improve luteal secretion and thereby provide a more thorough preparation of the endometrium for the fertilized ovum. This theory might therefore be used to explain the successful results recently reported in this *Journal* by Christie Brown,⁷ who treated sterility and abortion with small doses of dienoestrol and progesterone, though according to Smith the progesterone is unnecessary.

Since the Smiths had claimed² that the toxæmias of late pregnancy are invariably preceded by a state of oestrogen and progesterone deficiency, it was natural that they should also inquire into the value of stilboestrol in the prevention of these conditions. They argue that it is unlikely to cure established toxæmia, because by the time signs appear syncytial degeneration and placental vascular damage are already present and the placenta is incapable of increasing its hormone production even under an extrinsic stimulus. Encouraging results were obtained in the prophylactic treatment of 95 patients, only 18 of whose previous 197 pregnancies had been normal. Late pregnancy toxæmia and premature labour are relatively common in women with essential hypertension, yet in 17 hypertensive patients a 42% foetal loss sustained in previous pregnancies was reduced to 12% with this treatment. Again, 11 pregnant diabetic women, whose 13 previous pregnancies had resulted in only two living babies, produced eight living children following routine stilboestrol therapy, and none of them developed toxæmia. Three of the babies were large, which tends to support the statement by Barns⁸ in a paper recently published in this *Journal* that there is no apparent connexion between the large size of babies of diabetic mothers and the presence of hormone imbalance or toxæmia in the mother.

The complicated theoretical basis of Smith's work may not meet with general acceptance. For instance, there is little evidence as yet to support the idea that the production of hormones by the placenta is under endocrine control. Again, other workers⁹ have failed to find that a fall in oestrogen and progesterone output invariably precedes the development of toxæmia. Furthermore Davis and Fugo¹⁰ gave stilboestrol to ten pregnant women and found no increase in pregnanediol excretion, though after the administration of progesterone this was increased. Their cases, however, were normal pregnancies, while Smith's original

work¹¹ was carried out on pregnant diabetic women; and their dosage of stilboestrol was considered by Smith to be so excessive that it might depress rather than enhance placental function. It could also be argued that the general care and close supervision which inevitably accompany any special therapeutic trial might in part explain the good results. Indeed, all manner of theoretical and practical questions arise, but the latter at least might be settled by observing the results of giving stilboestrol as a routine during pregnancy in further large-scale, carefully controlled clinical experiments.

GONORRHOEA IN WAR

The management of gonorrhoea in the second world war was very different from that in the first. The sulphonamides, which became available in 1937, and penicillin, which was first used in the treatment of gonorrhoea about May, 1943, completely changed the outlook. Whereas in the first world war enormous numbers of patients languished in large hospitals for weeks or even months, in the second a few days in hospital was the rule, and many Service patients were not even admitted to hospital but, particularly in the U.S. Forces, were treated on a "duty status." The incidence of complications fell from 28% in 1937 to less than 1% in 1944, and after the introduction of sulphonamide therapy the proportion of "carriers" decreased from between 5-20% to negligible figures. The progress made in World War II has been described by Altshuler,¹ who explains what lay behind the various orders issued for the management of gonorrhoea in the U.S. Army. The first of the sulphonamides to be used for this purpose was sulphanilamide, and this was succeeded in turn by sulphapyridine, sulphathiazole, and sulphadiazine. In 1941 the usual course of treatment was 19 g. of sulphathiazole in nine days, but it soon became apparent that 20 g. in five days gave better results, being successful in something like 75% of cases. When the first course failed a second similar one was given after five days, and in 1943 this second course was increased to 33 g. in five days. About this time sulphonamide resistance became a serious problem, with increasing numbers of patients failing to react. Many hospital beds were blocked, and morale suffered considerably. Almost the only effective treatment in such cases was hyperpyrexia; this meant maintaining the patient's rectal temperature at 105.8° F. (41° C.)-106.2° F. (41.2° C.) for eight hours—a procedure requiring much labour and skill, and by no means without risk.

Early in 1943 penicillin was found to be very effective against the gonococcus, and by June in that year 1,600 patients had been successfully treated on various dosage schedules. At first 10,000 units of penicillin were given every three hours for five doses, and if this failed 10,000 units were injected every hour for ten hours. These schedules were modified from time to time. One retained for a long period was 100,000 units in 15 hours. Later this was increased to 200,000 units, with correspondingly larger total doses in cases of relapse. Towards the end of 1945 there were indications that the gonococcus was developing some slight degree of penicillin resistance, and it was feared that the sulphonamide experience would be repeated. However, no well-authenticated case has yet been recorded, and most of the supposed cases have been due to faulty technique, insufficient dosage, or relatively inactive preparations of the drug. Relapse and development of the carrier state both proved to be much less common after penicillin than after sulphonamide therapy. In order to save the trouble of repeated injections various methods of prolonging the action of penicillin in the body

by delaying absorption or excretion were investigated. Penicillin in peanut oil and beeswax proved effective and popular, though the viscosity of the preparation is troublesome; recently procaine penicillin in oil has come into use. With this preparation penicillin in the blood can be maintained at an effective level for 24 hours or so. At room temperature the solution will pass easily through an ordinary intramuscular needle. The use of penicillin made practicable the out-patient treatment of Servicemen suffering from gonorrhoea, and in the U.S. Forces this became the rule in 1945, though in the British Army the patient was normally seen by a specialist venereologist and "detained" for 24 to 48 hours—a more economic procedure than admission to hospital. Diagnosis in the Services has always presented a problem, since the normal "medical inspection room" or other centre to which a Service man ordinarily reports sick contains no facilities for smear or culture work, and a diagnosis of gonorrhoea is never justified (either in the U.S. or British Forces) on clinical grounds only. In the male a smear alone is usually sufficient, but in the female a culture is frequently necessary as well, particularly in subacute or chronic cases. However, the great majority of Service women suspected to be suffering from gonorrhoea were admitted to hospital for examination and treatment.

Criteria of cure were more exacting in the British than in the U.S. Forces. In the former three months' observation, with periodical clinical and pathological examinations, was the rule for both sexes; in the latter, three weeks' observation for men and three months' for women were considered adequate. One reason for this discrepancy was the much freer availability in the American Forces of penicillin, which was provided for the treatment of gonorrhoea in the latter long before similar provision was made for the British. The remaining problem was to determine the necessary period of observation in order not to miss a concurrently acquired syphilitic infection in patients who developed gonorrhoea and were treated with penicillin: opinions differ about how long this should be, but most authorities consider the period should be four months at least, and preferably six, while some put it at twelve. There can be no doubt that the treatment of gonorrhoea was one of the great medical triumphs of the war. Penicillin reduced what was a very serious medical problem to negligible proportions, and if it did not appreciably reduce the incidence of the disease it must have saved many thousands of hospital days, and thus much expense and manpower.

MUSCLE BIOPSY IN RHEUMATOID ARTHRITIS

The comprehensive term "rheumatism" has long been recognized to include a variety of conditions of different aetiology, and any unification that may be attempted in future must depend on something more than the common factor of pains in the limbs. One promising method of investigating the rheumatism problem was evolved by Curtis and Pollard¹ in America. They obtained from patients with rheumatoid arthritis pieces of skin and calf muscle in parts remote from the affected joints: these biopsies showed the presence of small foci of round cells of chronic inflammatory type. Two years later Freund and his co-workers² demonstrated similar inflammatory nodules in the nerve sheaths of patients with rheumatoid arthritis, and they followed up this work by confirming the results of Curtis and Pollard.³ In this country Gibson, Kersley,

⁵ *Ibid.*, 1948, 7, 132.

¹¹ *Amer. J. Syph.*, 1943, 32, 115.

and Desmarais carried out a series of similar investigations and showed that the pathological lesions in muscle were of two kinds: (1) pericapillary collections of lymphocytes, plasma cells, and sometimes eosinophils, between the muscle fibres; and (2) paravascular collections of lymphocytes only, associated with sclerotic arterioles in the perimysium. They also found similar lesions in the perineurium of the radial nerve and in the fat surrounding the synovial membrane of the knee-joint.

More recently the same authors⁵ have examined biopsy material obtained, not only from patients with rheumatoid arthritis, but also from patients suffering from joint pains caused by other conditions, which included non-specific polyarthritis, post-gonorrhoeal arthritis, acute and subacute rheumatism, osteoarthritis, spondylitis ankylopoietica, gout, and Still's disease. Fifteen non-rheumatic patients were used as controls. The patients with polyarthritis were divided into two groups, one with a diagnosis of idiopathic rheumatoid arthritis and the other with a diagnosis of non-specific infective arthritis. Typical lesions were found in the muscles of 34 of the 56 cases in the former group (60.7%), but their incidence appeared to have no relationship to the activity of the disease as estimated by the severity of the symptoms, muscle wasting, or the blood sedimentation rate. The duration of the patients' symptoms, however, seemed to be a more closely connected factor. Clear-cut negative results were obtained in spondylitis ankylopoietica, rheumatic fever, and post-gonorrhoeal arthritis, as well as in the fifteen non-rheumatic controls. Out of the seven cases of osteoarthritis and the five cases of gout there was only one doubtful muscle lesion in each group; in the four cases of non-specific infective arthritis there were changes in muscle and synovial membrane in one, and in the synovial membrane only in two; there was a muscle lesion in one of the three cases of Still's disease and a skin lesion in another; and out of the four cases with subacute rheumatism and cardiac involvement a skin lesion only was found in one.

These lesions, therefore, are not specific, but occur in a significantly high proportion of cases of rheumatoid arthritis, hardly at all in osteoarthritis, and not at all in spondylitis ankylopoietica. Kersley and his colleagues suggest that muscle biopsy might be used as an aid to diagnosis in difficult cases, but since muscle lesions were found in less than two out of three of their patients with rheumatoid arthritis it is difficult to see what significance a negative finding would possess. The value of the work lies in its demonstration that rheumatoid arthritis is not localized to periarticular tissues but is a disease causing widespread pathological changes in mesodermal tissues, of which lesions in muscle are only a part. The negative results obtained from muscle biopsies in the case of osteoarthritis and spondylitis ankylopoietica suggest that the origin of these diseases differs from that of rheumatoid arthritis.

RADIATION AND LYMPHOCYTES

A method of detecting changes in the blood of persons exposed to ionizing radiations has been described by Dickie and Hempelmann.¹ They carried out blood examinations on 364 individuals, 195 of whom were either exposed to small doses of various kinds of radiation, or worked with radioactive material, or were exposed to uranium in the form of oxide fumes; the remaining 169 individuals were not so exposed, and acted as controls. Using supravital staining methods, they recorded the presence or absence of neutral red granules (Gall's granules) in the lymphocytes, and they were able to

show that in the lymphocytes of the individuals exposed to radiation and uranium fumes abnormally large numbers of these granules were present before any change in the total lymphocyte count occurred. In order to obtain satisfactory preparations the authors had to use stronger solutions of dyes than are customarily employed, and they found that phase-contrast microscopy was of much assistance in detecting the inclusions, which they believed to be granular in composition. Analysis of their findings also showed that there was a significant reduction in the total number of leucocytes in the workers exposed to radiations compared with the individuals in the control group. If the results of this research are confirmed, a further method of checking the health of workers in these dangerous occupations will be available.

THE TREATMENT OF NOMA

Noma, or cancerum oris, is fortunately rare in Western Europe, though during the war it was not uncommon among those confined in internment camps. It can still be seen in children and occasionally in adults in Africa, South America, and India, and in the last country it sometimes occurs as a complication of kala azar. Its exact aetiology is not known, but the associated infection is due to spirochaetes and fusiform bacilli, accompanied by diphtheroids and streptococci—organisms also present in tropical ulcers, ulcerative stomatitis, and Vincent's angina. If these organisms are removed the lesions heal. A decrease in the numbers of polymorphonuclear leucocytes, such as occurs in inanition and agranulocytosis, appears to be an essential precursor of noma. Good results were occasionally obtained with local applications of cod-liver oil or with sulphonamides,² but in 1944 Findlay, Hill, and Macpherson³ reported the successful treatment with parenteral penicillin of two cases of noma in tropical Africa. Confirmation of the value of penicillin came from Benhamou and his colleagues⁴ in North Africa, who successfully treated five cases and from Vaizey,⁵ who cured two children and one adult in Ethiopia. Among the starving prisoners in Belsen there were several with noma. Dawson⁶ treated five patients with penicillin intramuscularly and sulphonamides and penicillin locally. Four were cured, but one did not respond to this treatment. For children 300,000 units of penicillin in three days would appear to be a minimal dose. The results are often quickly apparent, as in the case recently reported by Dr. D. Mackay⁷ in this *Journal*, in which improvement was obvious within 24 hours. Dana and his colleagues⁸ used penicillin to cure a child who developed noma after being treated for syphilis with bismuth. There have been similar good reports from many parts of the world,⁹⁻¹⁶ but it sometimes happens that although the lesions clear up and the toxæmia decreases the patient may die from the extreme inanition which is probably responsible for the onset of noma. Only one failure to respond to penicillin treatment has so far been recorded, and it is clear that the mortality of noma, previously a very fatal disease, can be reduced to negligible proportions.

ISRAEL'S BEVERIDGE PLAN

NEW HEALTH SERVICES

The Beveridge Plan of 1942 aroused great interest in Palestine, specially among Jewish Agency leaders, who were then working on the assumption that they would form the nucleus of a Cabinet when Jewish independence was achieved. The Beveridge report was immediately translated into Hebrew by Mr. I. Kanievsky, an expert on social welfare and administration.

Social insurance in Palestine is exactly as old as it is here. In 1912, while Lloyd George was initiating national health insurance in this country, the *Histadruth*, which is the trade union confederation embracing most Jewish workers, founded the *Kupat Cholim* or sick fund. The pioneers in this movement were a handful of agricultural workers in Judaea and Galilee who were opening up a desolate and undeveloped area. Palestine was still under Turkish rule; settlers were rare birds distrusted not only by the Arabs but also by the old Jewish population in the towns. Such medicine as there was in this environment was synonymous with witchcraft, though probably less honoured. From these beginnings there developed a comprehensive health service covering 75% of all Jewish workers in Palestine, all paying a unified contribution according to earning capacity. Under the aegis of the *Histadruth* here were established health insurance schemes providing maternity benefit, an invalid fund, unemployment fund, and old age, widows', and orphans' funds.

Health services in Palestine, however, suffered from the lack of a single co-ordinated system of insurance. Many Jewish offices outside the General Federation of Labour provided facilities that did not always work in harmony with the main organization, and many schemes were still dependent on outside charity. The British were themselves developing social services to include the Arab population, which in Palestine was perhaps served better than anywhere in the Middle East. Some Arabs came within the framework of the *Kupat Cholim*, especially where Jews and Arabs were employed together. In these cases Arab workers received medical care against compulsory payments by their employers.

The Kanievsky Plan

A Cabinet subcommittee is now working on draft proposals to centralize these different schemes so as to include all the citizens of Israel. Administration will be the responsibility of the Ministry of Social Welfare under Mr. I. M. Levin, the Minister, a comparatively new immigrant to Israel who escaped from the Warsaw ghetto. This special subcommittee has the task of putting the "Plan for Social Insurance in the State of Israel," commonly called the Kanievsky Plan, into operation. This plan was first submitted to the *Histadruth* executive, which sponsored the research, in May, 1948. It includes the following main points:

1.—Free medical aid, including hospital treatment, for all citizens of Israel.

2.—Compulsory social insurance for all wage-earners, including members of the free professions, artisans, etc.

This insurance scheme will include medical treatment; workmen's compensation; special allowance for expectant mothers and maternity aid; assistance to invalids; unemployment insurance; old age pensions and assistance to widows and orphans. According to the original plan the scheme will be financed from contributions by employees, employers, and the State. These contributions would correspond to 8% of the employee's wages; 5% contributed by the employee, 8% by the employer, and 5% by the State.

Taking into consideration the rapidly changing structure of Israel's population, which is expected to be doubled within the next four years, such a plan can be carried out only step by step. The general opinion is that the first step would be the provision of free hospital treatment for the whole population. At present the available accommodation in Israel's civilian hospitals is only 2 beds per 1,000 population. However, there are a number of military hospitals which should soon be at the disposal of the Government. In addition, the Government and existing medical organizations are already considering plans or the early establishment of many new and modern hospitals, and to this "capital investment" it is expected that the Jewish Agency, the international Zionist fund-raising organization, will make its contribution.

In implementing this scheme it is not intended to abolish the present status of physicians in private practice. A large proportion of the country's medical profession may find employment in these Government schemes, but the remaining private practitioners will not lack work.

The Cabinet subcommittee, headed by Mr. Kanievsky, is composed of the Directors-General of the Ministries of Finance and Health and Social Welfare, three specialists whose experience during the Mandate and in the government departments of other nations should prove valuable. The main employers' associations have not yet had time to consider the plan officially and so far have not made their views known. But in view of the fact that such schemes are already in operation in almost all progressive countries it is believed that opposition to the plan will not be too strong, although some of the employers' representatives feel that the introduction of such a comprehensive plan may be premature.

WOUNDED AND SICK PRISONERS
OF WAR

DRAFT RED CROSS CONVENTIONS

A Red Cross draft convention which the diplomatic conference referred to last week (p. 768) is studying at Geneva lays down regulations concerning the mixed medical commissions appointed on the outbreak of hostilities to examine wounded and sick prisoners of war. Each of these commissions is to be composed of three members—two belonging to a neutral country (one of whom is to be the chairman) and the third to the detaining power. The neutral members are to be appointed by the International Committee of the Red Cross and approved by the two belligerent powers. If possible, one of the neutrals should be a physician and the other a surgeon. They are required to be entirely independent of the warring powers, which must grant them all facilities in discharge of their duties, including a visit to each prisoner-of-war camp at intervals not exceeding six months. These mixed medical commissions may either propose repatriation or may refer a prisoner for a later examination, and the detaining power is required to carry out these decisions within three months. A proposed regulation not in the existing (1929) Geneva Convention for the Wounded and Sick is that prisoners of war who, in the opinion of the medical authorities of the detaining power, are manifestly in a serious condition shall be repatriated without having to be examined by the commission.

Prisoners of war who are to be repatriated direct, according to a draft model agreement which has been drawn up, include all wounded prisoners suffering from lesions equivalent at least to the loss of a hand or foot, and all sick and wounded in whom recovery appears to be unlikely within a year. Prisoners of war eligible for accommodation in a neutral country include those who have better chances of recovery in such a country than in captivity; those suffering from any form of tuberculosis and whose treatment in a neutral country is likely to lead to recovery or to considerable improvement; those suffering from other conditions in which treatment would clearly have better results in a neutral country; those who have undergone a nephrectomy as prisoners; cases of osteomyelitis latent or on the way to recovery, of diabetes mellitus not requiring insulin, and of exanthematic typhus acquired in captivity. Cases of captivity neurosis not cured or on the way to complete cure after three months in a neutral country are to be repatriated. Excluded from accommodation in a neutral country are all cases of duly verified mental affections; prisoners with nervous affections, whether organic or functional, considered to be incurable; chronic alcoholics; and all cases of contagious disease during the infective period, with the exception of tuberculosis.

A list of conditions has been set out in which the decision of the mixed medical commission must be based to a great extent on records kept by camp physicians and prisoner doctors of the same nationality, or on an examination by medical specialists of the detaining power. These include chronic asthma and bronchitis, chronic cholecystitis, serious chronic diseases of the central and peripheral nervous system, and auditory disorders, such as total unilateral deafness, if the other ear does not discern the spoken word at a distance of one metre.

Marking of Hospital Ships

Some work on the visibility of hospital ships has been undertaken by the research laboratory of the Admiralty and laid before the conference. The present convention states that hospital ships shall be painted white and display vermilion red crosses, three of them, of a height of three metres, on each side of the hull, two others in a horizontal position so as to be plainly visible from the air, and two more vertically above the main deck, one to be seen from astern and the other from ahead. During darkness or reduced visibility the crosses on each side of the hull are to be floodlit and the crosses on the superstructure to be made luminous by means of lamps. There are also provisions for an automatic switching mechanism to give flashing or alternating illumination.

The Admiralty experiments suggest that these devices may not be the best possible. In daylight, at the range at which a ship is first seen, there is no possibility of identifying a vessel as a hospital ship. In many cases the range must be halved before recognition is possible, and sometimes, as with the white hospital ship of the Geneva convention, which is most difficult to identify because it can easily be confused with a warship painted a light grey, the range must be reduced to one-third or one-quarter before identification can be certain, and even then the first recognition is not of the painted red cross. The proposal is that a hospital ship should be painted black and light yellow (or white) on either side of a vertical line drawn at the mid-point of the length of the ship, and that the black half should carry a yellow or white cross and the yellow or white half a black cross. With such a design the unmistakable half-and-half pattern first shows itself, and the crosses appear later. The object of introducing yellow, with its high reflectivity, is to obtain any advantage due to colour. Some complicated experiments have been carried out on the required dimensions of the cross if it is to be seen under varying conditions of meteorological visibility. Under some conditions if the cross is to be seen at all it would have to be of a height which is usually impracticable. The only recommendation on the point which can be made is that the cross should be the full height of the freeboard of the ship and larger if possible. The most conspicuous cross is one which has a thickness of limb equal to one-quarter of its height, and a red cross must be about 10% larger than a black cross to give equal ease of recognition under the same viewing conditions.

For visibility of hospital ships at night the Admiralty workers advise against floodlighting, and consider that luminous signs are preferable. However well floodlighting may be arranged, a red cross on a white ground will at a distance, if any atmospheric haze is present, give a whitish glow with few distinguishing features. The better plan is to use diffusing glass with s of lamps behind it.

Preparations and Appliances

EXPULSION OF VACCINE LYMPH FROM CAPILLARY TUBES

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH writes: Antismallpox vaccine lymph is now put up in capillary tubes which are not of uniform size, and the special device that used to be sold for expelling the lymph from the tubes is not always readily available and is sometimes ineffective. A simple alternative is to use a baby's feeding-bottle teat, the open end of which is easily occluded by the thumb. The teat can be sterilized by boiling, and the nipple hole is usually about the right size to make an airtight joint with a capillary tube.

Another method, suggested by Dr. O. H. Bowen, of Kingsbury, N.W.9, is to break off both ends of the lymph tube and then to insert into one of the open ends the sterilized needle of a hypodermic syringe with the plunger pulled out. If the junction of tube and needle is surrounded by a small sterile pledget of wet cotton-wool to make an airtight joint the lymph can be expelled without difficulty by pushing down the plunger of the syringe. It is obvious that care must be taken to sterilize needle and syringe before they are used for other purposes.

Reports of Societies

PATHOLOGICAL TESTS IN RHEUMATIC DISEASE

A meeting of the Section of Physical Medicine of the Royal Society of Medicine on April 13 was devoted to a discussion of the significance of pathological tests in rheumatic disease. The president, Dr. L. C. HILL, was in the chair.

Dr. D. H. COLLINS discussed the contribution which the histologist or cytologist could make to the diagnosis and management of the patient who presented himself at the rheumatism clinic. Investigations requiring the removal of material by aspiration or excision biopsy were not applicable in all cases, but where they could be employed usefully direct information about the pathological process could often be obtained.

If the fluid in an acutely inflamed joint was withdrawn and examined, septic arthritis could be identified by the presence of pus and organisms. Traumatic effusions always contained either blood or blood pigments. Many investigations had been made on the mucin content of synovial effusions. Although generally the mucin content and viscosity of an inflammatory effusion were low and of an effusion due to osteoarthritis high this examination was of little value in differential diagnosis because it was never known to what extent the bulk of the effusion was contributed to by watery transudate.

Synovial biopsy in cases of suspected tuberculous arthritis was a routine procedure. It should be used in all cases of arthritis where there was a possibility of tuberculosis, especially in monarticular disease. A positive histological diagnosis could almost always be made in cases of rheumatoid arthritis when the following five features were found together: hyperplasia of the synovial membrane and villi; hyperplasia of the synovial lining; massive lymphocytic or plasma-cell infiltration; inflammatory hyperaemia and oedema varying in degree with the duration and intensity of the inflammatory process; and absence of other specific histological characters. This histological diagnosis of rheumatoid arthritis must be considered of course, in relation to the clinical features, but he was sure that it had prognostic value and probably diagnostic value, even in the monarticular case; but unless the five features were clearly recognizable the diagnosis of rheumatoid arthritis was not justified.

Relative Viscosity of Blood Plasma

Dr. H. J. GIBSON confined himself to a discussion of the relative viscosity of blood plasma in comparison with other empirical tests of rheumatic disease. The estimation of plasma protein changes was of value in diagnosis, especially in the rheumatic group, and in the objective assessment of activity. Such estimations were also important tests of cure. The blood sedimentation rate had been the sheet anchor in investigation it had stood the test of time, and there must be few rheumatism clinics in which it was not used extensively. Its advantages were the ease with which it was carried out and the understanding they had of its interpretation. The disadvantage of the blood sedimentation test was that it was an indirect estimation: a plasma abnormality was tested for by the effect on second reagent—namely, the red blood cells. Plasma was already a very complicated physico-chemical system, and when red blood cells were added the picture became still more complicated. If a test could be found which would eliminate the use of red cells and would estimate abnormalities in the plasma directly, a great advance would be made. A formalin gel test and a colloidal gold test had been described. The latter might be positive in about 75% of cases of rheumatoid arthritis—strongly positive reaction being found only in about 50%—but this test did not correlate well with the blood sedimentation rate. It appeared to estimate a different abnormality, although both abnormalities might be the result of the disease.

The increase of plasma viscosity was an old observation, but recent work had revived interest in it. The test was applied first in cases of tuberculosis, and a high correlation was found between clinical activity and the viscosity zone—a rather narrow zone—associated with pleural effusions. It was found in tuberculosis that normal viscosity might be found first in the

early stages and later in remissions, and also, rather paradoxically, in the terminal stages of the disease.

This work seemed to be of interest as proposing a relatively simple test which might replace the blood sedimentation rate or supplement the information it afforded. It was an estimate of the viscosity of plasma relative to distilled water, carried out at 20° C. with undiluted oxalated plasma. Dr. Gibson showed the results obtained in 365 observations on 286 cases of rheumatoid arthritis, the relative viscosity and the sedimentation index being correlated. The activity of the disease was reflected in the results with both tests, though detailed correlation was difficult to discern. In this series of cases, if the blood sedimentation rate only was examined, abnormalities shown by viscosity readings would have been missed in 13 observations, and if the viscosity only had been taken abnormalities shown by the blood sedimentation rate would have been missed in 20 observations. Abnormalities were demonstrated by both tests in 94.2% of the observations. There was thus an advantage in carrying out both tests if the maximum abnormality was to be ascertained. The inferences to be drawn from the tests were concurrent, and yet the tests were not testing quite the same thing.

Indeed, the value of the viscosity test was that it did not appear to be estimating the same abnormality as the blood sedimentation rate. The abnormalities were different, or at least were different facets of the same plasma abnormality. He was not advocating that the blood sedimentation rate be abandoned. There was a place for both tests, especially in cases where it was desired to have close supervision and control, as, for example, in therapeutic trials. If there were two different indices of improvement or deterioration to hand to the statistician it was a great advantage. The tests should be regarded as complementary.

Asked whether the cases in which there was a discrepancy between the relative viscosity and the sedimentation rate had been checked back clinically to exclude the possibility of some other infection such as a cold or influenza, Dr. Gibson explained that it was not a single observation which was made in these cases, it was a follow-through observation, and the discrepancy existed throughout. He added that he had avoided mentioning individual cases, because in rheumatism "almost anything can be proved by selecting your cases."

The brief ensuing discussion, in which Dr. W. S. TEGNER, Dr. J. HARKNESS, and Dr. COKE participated, was mostly concerned with the types and use of viscometers and the desirability of standardization.

ULSTER PAEDIATRIC SOCIETY

The inaugural meeting of the Ulster Paediatric Society was held in the Royal Belfast Hospital for Sick Children on April 5. Dr. ROWLAND HILL was elected chairman, and Dr. W. A. B. CAMPBELL honorary secretary. The main business of the meeting was to draw up the constitution and rules of the Society, after which the film "Patent Ductus Arteriosus" was shown. It is planned to hold at least three clinical meetings in each year.

A meeting of the North of England Obstetrical and Gynaecological Society was held in the Jessop Hospital, Sheffield, on March 18, with the president, Mr. S. B. HERD, in the chair. Mr. O. V. JONES, of Bangor, described a case of hydatidiform mole. The pathological findings in this case were discussed by Dr. G. EVANS. Dr. C. G. PAINÉ described a case of haemolytic disease in a newborn child with group A Rh-positive blood, the mother's blood being group O Rh-positive. Mr. P. MALPAS reviewed the gynaecological aspects of regional ileitis.

The Nurses and Midwives Whitley Council announces that it has agreed on the following revised rate of remuneration for student district nurses: £140 per annum plus emoluments valued at £100 per annum, or a living-out allowance of £100 per annum for non-resident students. As this is part of the student-nurse settlement, which came into operation on Sept. 1, 1948, the new rates will apply retrospectively to that date. If in any case an existing student would receive a lower rate of remuneration under these arrangements than before, the present rate may be continued on a personal basis. The new rate is provisional and may be revised. The rate previously paid to student district nurses in training for the certificate of the Queen's Institute of District Nursing was £95 per annum plus emoluments valued at £100 per annum.

Correspondence

An Unfortunate Precedent

SIR,—The fear of favouritism in respect of the Awards Committee is probably quite unfounded and, in the case of Lord Moran, of course ridiculous. But it seems to me that the ideal future composition of such a committee would include a chairman who was not a medical man at all but either an eminent jurist used to weighing evidence or a Fellow of the Royal Society of accepted standing and experience. The presidents of the Royal Colleges should be *ex-officio* members while in office, and the other members of the committee should be elected annually, biennially, or as seemed most practicable. This would minimize, if not abolish, any fear of favouritism and would probably also be acceptable to such people—of whom I happen to be one—as believe that the Royal Colleges should be mainly concerned with preserving and fostering the educational and ethical standards of the profession and not meddle—*qua* colleges—with such questions as salaries, fees, and mileage.—I am, etc.,

Easton Royal, Wilts.

H. H. BASHFORD.

SIR,—Your courageous and pertinent leading article (April 23, p. 717) on the above has produced an undignified reply from the inner cabal of the Royal College. The eight signatories of this reply not unnaturally regard themselves as the henchmen or bodyguard of their President; but in their haste to express their sharp resentment of your free criticism they expose the weakness of the regulations by virtue of which they hold office. And it is to these weaknesses that I wish to address myself rather than to the question whether you had not expressed simply and clearly what so many of us have felt and thought.

I wonder if the general body of practitioners, including the large number of Members, realize how the R.C.P. is actually governed in practice, or how much of their professional life is affected by the senior Royal College. Put as briefly as possible, it is as follows. In theory the whole body of Fellows rule and govern the College. In practice they do nothing of the kind. So archaic are some of their procedures that even to the present day the assembled Fellows at the meeting of the Comitia for the election of a President are solemnly presented *each with a half-crown*. By all means *revere and venerate* long-established custom when no harm is done thereby. But this ancient custom is merely a reminder of the time when the College of Physicians was essentially the College of the Physicians of London and attendance by the great majority could be expected.

It is still the rule that those actually present and voting are the only Fellows who can elect the President. But to-day Fellows of the highest repute and learning live and direct the studies of rising generations in parts of the world not even discovered when the charter of the Royal College was granted. These have no say or place in framing the policy of the College, nor have they even a representative committee, and still less nominees to the Council of the College. Are these exponents and judges of good medicine to be excluded merely because some rule was laid down before their country was known to exist?

From this one defect comes the majority of all the other defects in the College constitution. Once the President is re-elected the cabal reasserts its hold on all policy; and by diffusing an atmosphere of "Touch not established custom" subsequent meetings of the Fellows in Comitia all too often become formal and routine acceptance of the Council's recommendations. It is true that printed agenda are circulated to every Fellow containing the recommendations of the Council, and that these recommendations are technically open to discussion. But to question these instantly produces a sense of trespassing on strictly preserved coverts and using time that will produce no change.

What is the obvious result of such an atmosphere? It is and must be that unless a Fellow is *persona grata* to the inner

council, however good a counsellor he may be, or however anxious to give his best to the College, there is no probationary forum where he could be welcomed and tried out, and so he will probably remain outside. It is equally obvious that the whole body of Fellows scattered all over the world cannot run the day-to-day business of the College. But there is much room between the two extremes for moderate and sensible development without offence to our ancient foundation. In this gap there is ample space to make the rules of the College more consistent with twentieth-century methods of true democratic government.

To introduce changes that would bring the knowledge and advice of a wider circle of Fellows into the policies and development of the Royal College would find an immediate response from many who now realize that they have no means of contributing to these matters and are, therefore, irregular in their attendance at Comitias. The College would then rapidly become the deeply loved and respected head of all that is best in true world medicine. I feel that it is only dormant and waiting to be led back into its true path. Had this been the trend of the last nine years instead of efforts to entrench the established rules and to combine local and parochial medico-politics with the high office of President to which your article refers, then there would have been no occasion for your leading article. The joint position of P.R.C.P. and Chairman of the Awards Committee would have been unthinkable.

There are many other matters besides those that I have raised, such as conditions for the membership examination, that have long called for readjustment to the changed conditions of medicine.

The recent meeting of the Prime Ministers of the Commonwealth and the nature and result of their deliberations give true point to my argument.—I am, etc.,

London, W.1.

C. B. HEALD.

SIR,—The reply (April 30, p. 774) provoked by your leading article (April 23, p. 717) on the above subject and published over the signatures of the censors and other officials of the Royal College of Physicians will doubtless provoke much correspondence. May I, as a surgeon with no personal interest in merit awards, say that I believe you, Sir, in your article to have voiced the real views of the consultants and specialists in the country?

It is quite obvious to me that the gentlemen who have written the reply are, like too many distinguished members of the profession, completely out of touch with the realities of the situation that faces us and with the opinions of the rank and file of specialists. "The sympathetic attitude of the Minister of Health"—the expression is almost humorous, if the situation were not so serious. "Terms of service which are considered by most consultants and specialists to be just and generous"—when the truth is that most consultants and specialists are seriously perturbed and gravely dissatisfied with those terms, *when they are examined intelligently*.

Like some of the signatories, I am getting on in years, but I am not yet in my dotage and I *do* go to meetings and listen to the views of my younger colleagues. Whilst I appreciate the loyalty which rallied these gentlemen to the defence of their President, I tremble for the future of my profession when those who should be among its leaders are obviously so gravely misled as to the facts which face us and as to the feelings of their colleagues. I would beg them all to read, mark, learn, and inwardly digest your leading article at p. 762 of the *Journal* of April 30. Surely that will open their eyes a little.—I am, etc.,

Southport.

R. R. M. PORTER.

SIR,—If the fears expressed in your leading article (April 23, p. 717) and "Young Specialist's" letter (April 30, p. 774) are well founded the moral condition of our profession is such that the particular composition of an Awards Committee seems of small importance. The picture of the President on the one hand dispensing "awards for the boys," and a group of aspiring young specialists on the other silently stifling their valuable criticism or warm-hearted admiration with a weather eye on the awards barometer, should certainly cause concern;

though I suspect the reaction may generally be a rather more light-hearted one.

I do not share your pessimism, but fear that arguments of this sort if taken seriously may encourage faction at a time when harmonious unity for the main purposes of our profession is more important than it has ever been.—I am, etc.,

Oxford

C. W. M. WHITTY.

The Intervertebral Disk

SIR,—Mr. Michael Kelly misquotes me in his letter (April 23, p. 725) on the subject of the intervertebral disk. In the Mackenzie Lecture, an abridged edition of which was published in the *Journal* of Feb. 12 (p. 255), I did not say that "when a stooping man begins to extend his spine the posterior margin of the disk is compressed. . . ." This would imply that this condition invariably happened. In fact, it is only in exceptional circumstances, as I was at pains to prove, that this circumstance does arise.—I am, etc.,

London, W.1.

HUGH E. GRIFFITHS.

Use of the Term "Coliform"

SIR,—The term "coliform" has for some time had an obscure meaning and it has become increasingly clear that a definition is desirable. Those interested in medical and veterinary bacteriology have used it to embrace only the morphological characters of many species, not of *Bacterium coli* alone but of the dysenteric bacteria, the salmonella, and other Gram-negative rods similar to *Bacterium coli*. On the other hand, the term "coliform" is restricted by many water and dairy bacteriologists to those organisms which are not only morphologically similar to *Bacterium coli* but which resemble it in its cultural and biochemical characteristics; some have even regarded it as being synonymous with *Bacterium coli* of faecal origin.

Because of this confusion, and also because there is now a closer liaison between all those who study bacteria from whatever aspect, a committee of nine, representing this variety of interests, was appointed by the Society for General Microbiology and by the Society for Applied Bacteriology. This committee met on several occasions and discussed the matter from wide angles, and the relevant portion of their report is quoted below.

1. The term "coliform" means "like *Bacterium coli*." or "coli-like."

2. "Coliform" is an adjective and as such has no generic or ecological significance.

3. It is proposed that the term "coliform" should refer to *Gram-negative rods resembling Bacterium coli in morphology and staining reactions but not necessarily in cultural and biochemical characteristics*.

4. It is hoped that the widest publicity will be given to this definition to prevent the term being employed to define different specific types by different workers, or to restrict the term to particular branches of bacteriology.

The committee are convinced that the proposed definition is the only one satisfactory to all interests in bacteriology and are opposed to any definition based on ecology or biochemical reactions. They hope that bacteriologists in general will understand and agree upon the meaning of the term "coliform." Existing systems allow for classification of organisms grouped under the wide term now proposed.—We are, etc.,

Needle Biopsy of the Liver

SIR,—In his excellent paper on liver biopsy Dr. Richard Terry (April 16, p. 657) recommends local anaesthesia, and this seems to be the usual practice. However, it is worth considering whether this procedure is :ot better done under thiopentone anaesthesia. During the war years overseas, when mysterious diseases with enlargement of the liver were so common, it

was sometimes desirable to examine material by biopsy of liver, spleen, gland, or marrow before a diagnosis (e.g., of kala azar) could be determined. These procedures are all rather unpleasant, and tend to be associated in some measure with anxiety to patient and doctor alike. It was found that, if needs be, even three to four such procedures could be safely and expeditiously carried out by a team of workers using thiopentone anaesthesia.

There are several advantages: anxiety, pain, or discomfort are eliminated, and the operator is free to concentrate on the various manoeuvres without worrying about the patient's feelings. This added confidence also means a surer thrust, and if by any chance no tissue is obtained the puncture can be immediately repeated. Safety is increased, because absence of movement of the patient and his liver can be assured if the sole duty of one member of the team is to press firmly upwards from below the right costal margin, so that the liver is held fast against the diaphragm. The patient is always grouped first, and vitamin K is given no matter what the prothrombin time. Very firm pressure over the site of puncture is maintained for a few minutes as a precaution.

There has been only one untoward incident, and that not directly related to the biopsy. During the early phase of the anaesthetic, when the patient was apparently semi-conscious, he suddenly swung left and dealt the anaesthetist a shrewd blow amidships which crippled him, and then knocked the needle out of my waiting hand with his elbow. An able assistant restored the situation by reinserting the thiopentone needle into the vein whilst the biopsy needle was boiled up again. Liver tissue was then obtained without difficulty.

In this country liver biopsy alone is usually all that is required; but, if at all likely to be necessary, sternal puncture, for example, may conveniently be carried out at the same time under the same anaesthetic. Many will testify to the satisfactoriness of this technique, which has been used consistently over the past five years.—I am, etc.,

Herpes Zoster Recurring in a Baby

SIR.—The following case is reported, as it appears to be unusual.

The mother of a baby who was born on April 17, 1948, developed varicella when four months pregnant; she caught this from her daughter, who was attending day school. There were no complications. The gestation was otherwise normal. The child was delivered at full term—a spontaneous breech. She was breast fed for seven weeks and then given modified cow's milk four-hourly.

On June 7, 1948, the child developed a rash on the left side of the chest and back. This I first saw on the following day, when I found a typical herpes zoster with a distribution over the left scapular region, the left lateral chest wall, and the left breast. The lesions were kept dry, and cleared up spontaneously in about 14 days, leaving no scars. During the illness the feeding was changed to National dried milk, on which the child thrived.

On Dec. 29, 1948, the mother noticed a similar rash on the right scapular region. I saw the child the following day and found a similar typical herpes zoster rash distributed over the right scapular region, the right axilla, the right inner arm, and the left forearm and inner side of the wrist. Over the scapula the lesions were few and discrete, but the axilla and arm were covered with confluent patches of vesicles which faded out towards the ulnar border of the hand. At no time did I find any constitutional disturbance: there was no raised temperature, no anorexia, no loss of sleep, no apparent pain. The baby remained just as active as ever.

Vaccination was performed in August, 1948—i.e., about 8 weeks after the beginning of the first attack of shingles. There have been no sequelae.

C. H. JOHNSON.

Diparcol in Parkinsonism

SIR.—The article by Dr. R. S. Duff (April 9, p. 613) has been of great interest to me, as I too have been using the drug for some considerable time. After reading the paper by Sigwald, Bovet, and Dumont I sent for the original French drug "novocainique" (2987 R.P.), and have since been able to continue the treatment for over a year now by the courtesy

of the manufacturers of "diparcol" (the corresponding preparation), who kept me supplied until the drug was put on the market.

My experience, I must admit, consists of one case only, but as it is at great variance to that of Dr. Duff, and the result seems to have been more favourable, I feel I should put my own observations on record.

My patient was not a case of post-encephalitic Parkinsonism, but of Parkinson's disease proper (paralysis agitans). Like Dr. Duff, I started with a small amount, but then, according to the suggestion of Sigwald and Bovet, I gradually increased the dosage until the limit of tolerance was reached, which in this case I found to be 3 g. daily (12 tablets of 0.25 g.). Above that dosage the patient became very giddy, whereas a dosage below that amount increased the tremor. As advocated by the French authors, I also gave the patient tab. amphetamine sulphate, 5 mg., one tablet before breakfast and one before lunch. Further, I gave a sleeping-tablet at night, and like Dr. Duff continued for a while with the alkaloids. The results have been most striking. The tremor has disappeared for periods of one or two hours at a time—amounting to a total of about 12 hours per day—and was much reduced in severity.

The patient is a woman aged 64 who has been suffering from Parkinson's disease for about 11 years. It started with an accident, when her hand was caught in a wringer. The symptoms were aggravated during an air raid and two years later by an accident to her husband. At the time treatment was started she was quite helpless, could not walk, and was trembling all day. She was in a state of persistent stupor, did not take any notice of her surroundings, and was unable to remember anything. She had to be carried from her bedroom downstairs. Now, apart from the considerable reduction in her tremor, she is able to walk about, walk up and down stairs, wash up, set the table, cook a little, change her shoes, read a little, and even knit. She is very bright, and can take full part in everyday life.

In conclusion I wish to point out that, apart from the cases of post-encephalitic Parkinsonism, the drug appears also to be applicable in cases of Parkinson's disease. The maximum dosage should be assessed individually by very gradual increases or decreases. It can be much higher than 1 g. (given as maximum dose by Dr. Duff), as proved in my case, where the optimum dose was 3 g. Drowsiness, cramp, and depression in the initial stages seem to be controlled by the addition of amphetamine sulphate, which is well tolerated by patients with Parkinson's disease. Indeed, these side effects seem to be more pronounced with the smaller dosage, and disappear as the amount of diparcol is being increased.—I am, etc.,

Spennymoor, Co. Durham

E. BRAUER.

Vertigo and Influenza

SIR.—Dr. A. H. Gregson (April 16, p. 683) mentions vertigo as a symptom in some cases of influenza. In the last few weeks I have seen four patients in whom severe vertigo was the presenting symptom, and in two of them the only symptom. Whether they were cases of influenza I cannot say, but at the time I regarded them as cases of acute influenzal labyrinthitis.

The first case will serve as typical of the others. He was a man of 70, who came staggering into the surgery as though drunk. He had been perfectly fit the night before on going to bed, but was woken up in the night by violent giddiness. The furniture appeared to be going round from right to left, and when he tried to walk he always fell towards the left side. He vomited and retched the whole night. He had slight nystagmus on looking to the right, but no other abnormalities in the C.N.S. On inquiry, he admitted to a fairly severe lumbosacral backache and a frontal headache, but had no other influenzal symptoms. Temperature and pulse were normal. The vertigo gradually wore off after some three days, and for a further week he got short attacks if he turned his head suddenly. His wife and daughter went down with typical influenza five days later. It will be seen that the evidence for this being a case of influenzal labyrinthitis rests only on the presence of the concomitant headache and backache, and the fact, which incidentally I prophesied, that other cases of influenza followed in this household.

The other three cases were similar. In all the onset was unexpected;—one moment the patient was perfectly well, the next moment he would be hanging on to the furniture to keep upright.

The experience was apparently very alarming. Three of the patients were elderly, and two of them said afterwards that they had thought they were going to die. The fourth was a child of 3, and her mother said that she was terrified during the attack. Three of the four had severe vomiting, and all were very consistent in describing objects as rotating about a vertical axis, and always in the same direction. All tended to fall towards the side to which objects seemed to rotate. After the acute attack, which lasted one to three days, all tended to get minor recurrences on rapid rotation of the head. Two had nystagmus on looking away from the side to which they tended to fall. Subjectively, none complained of deafness. Objectively, one had been stone deaf for years, and two others showed differences in auditory acuity between their two ears, but in view of their ages this was of doubtful significance. The child was not tested. Three of the four occurred in influenzal households, but two of them had no concomitant influenzal symptoms.

In any household in which some members have influenza it is a common occurrence for others to develop either a lumbosacral backache, frontal headache, muscle pains, or giddiness. If one assumes that these are abortive cases of influenza it seems reasonable to suppose that severe vertigo may also occur as the sole manifestation of influenza.—I am, etc.,

Great Dunmow, Essex.

PETER A. WALFORD.

Marriage Neurosis

SIR,—Dr. R. Macdonald Ladell (April 9, p. 635) revives the old controversy of E.C.T. versus psychotherapy. There are, I fear, many wrong assumptions in Dr. Ladell's communication. In the first place he appears to suggest that if a psychic stress can be unearthed there is no place for E.C.T. This is really a dangerous doctrine.

Those of us who use E.C.T. daily are often only too well aware of stresses which have at least helped to produce, say, an anxiety state or a condition of involutional melancholia. Often the patients themselves are only too conscious of these stresses. (A few days ago I saw two sisters who had both displayed anxiety symptoms from the death of their mother one and a half years ago. Both, I feel sure, will rapidly clear up with E.C.T.) To withhold E.C.T. in such cases could result in much unwarrantable suffering on the part of the patients, not to speak of risks of disaster—e.g., suicide.

E.C.T. intelligently applied, with, whenever possible, the patient's co-operation and after a careful physical and psychological examination, is one of the great boons of modern psychiatry. It can cut short all varieties of anxiety and depression, and in many cases the patient is more efficient mentally after its use than almost at any time in his life. (Old, unnoticed, mild states of depression and apprehension which may have existed for years before the acute breakdown are usually also swept away.) It can be used in extreme old age, and is usually a life-saver in delirious cases, which may be almost moribund on admission. Therefore, because some may use this treatment unintelligently, I would deprecate Dr. Ladell's suggestion that "the advocates of E.C.T. made no attempt to understand the cases and thus were turning their backs on all we have learned about the origins and meaning of neurosis during the last fifty years."—I am, etc.,

Armagh, N. Ireland.

ROBERT THOMPSON.

Treatment of Varicose Veins

SIR,—In his letter on the treatment of varicose veins (March 19, p. 500) Dr. H. M. Hanschell sets forth his experiences and disappointments with sclerosing agents. He (and others) describes how recanalization of veins takes place in a high percentage of cases following their apparent obliteration by this method. He goes on to describe an operation which in his hands, over a large series of cases, has given excellent results.

This most interesting letter was answered by Mr. R. Rowden Foote (April 9, p. 635), who, although obviously disagreeing with Dr. Hanschell, fails to put forward any evidence refuting Dr. Hanschell's argument against the use of sclerosing substances, and who instead devotes the major part of his letter to the irrelevancy of ulcer, which Dr. Hanschell never mentioned. He ignores the real point at issue, which is whether or not the injection of sclerosants is justifiable, in view of the high recurrence rate as compared with the very much better

results following ligation or extirpation by the method which Dr. Hanschell advocates.

In Mr. Rowden Foote's book on this subject it is stated that 85% of varicose veins treated by sclerosing injections had recurred, and furthermore he accepts figures which show that these recurrences are for the most part due to recanalization of the thrombosed veins. It seems reasonable, therefore, to assume that by removing a varicose vein entirely any recurrence can be due only to the formation of new varices in the superficial venous system—an event which is responsible for only 15–25% of recurrences and eliminates the large group of recurrences due to recanalization.

Dr. Hanschell has described a reasonable operative technique which in his hands has given splendid results, but Mr. Rowden Foote has scorned it on the grounds that this treatment has a long history of failures. Granted the principle of the operation may be associated with lack of success when older operative methods are used, but judging from Dr. Hanschell's result it would appear that his method has overcome most of the disadvantages associated with other operations designed to eradicate this condition and at least is worthy of more consideration than has been accorded to it by Mr. Rowden Foote.

Finally, may I draw attention to the virtues of the operation which in the past few months I have carried out a number of times? The operation itself is simple, the patient suffers very little pain and the minimum of inconvenience, and the cosmetic results are good. Thus far have I satisfied myself that Dr. Hanschell's claims for this method of treatment are well founded. What percentage of my own cases will recur I cannot know until I have followed them up for some years, but if my results are as good as Dr. Hanschell's I shall be satisfied the sclerosants have indeed a limited place in the treatment of this condition; and this has already become more than a mere suspicion, following some years' experience of injection therapy in treating varicose veins.—I am, etc.,

Dublin.

NORMAN RUTHERFORD.

Pressure Cooking

SIR,—The paper by Miss Gweneth M. Chappell and Miss Audrey M. Hamilton (April 2, p. 574) and your annotation (p. 582) on the effect of pressure cooking on vitamins are of topical interest, but consider only one aspect of pressure cooking. Some years ago Dr. P. Kouchakoff described experiments he had undertaken to determine the relationship between cooked food and post-prandial leucocytosis (*Lancet*, 1937, 1, 425). He was able to prove by a large number of tests that post-prandial leucocytosis occurs only after the ingestion of cooked food, but not after the same food consumed raw, and that in order to produce a post-prandial leucocytosis the food has to be heated above 83°–87° C., according to the kind of food.

Kouchakoff therefore assumed that heating of food above the critical temperature of 83°–87° C. produces toxic substances in the food and that the leucocytosis is a defensive reaction against these toxins. Furthermore, he found that no leucocytosis occurs when raw food is consumed simultaneously with the cooked food, as, for example, when eating a raw salad with cooked meat. But when the food has been heated above 100° C., as in the case of canned food or of pressure cooking, no amount of added raw food is capable of preventing the post-prandial leucocytosis. If Dr. Kouchakoff's main thesis is right, then routine pressure cooking should be condemned, even though it does not destroy the various vitamins.

I know that a number of physiologists deny the existence of a post-prandial leucocytosis, but this is perhaps because in their tests they failed to differentiate between raw and cooked food.—I am, etc.,

St. Peter Port, Guernsey.

A. ORLEY.

Handling of Corned Beef

SIR,—I have been appalled at the way tinned corned beef, used to make up the meat ration, is served to the public. The procedure in the majority of butchers' shops is to open a large tin of corned beef and place the contents on a wooden cutting board. The same knife used for cutting uncooked sausages, uncooked beef, uncooked mutton, uncooked pork, and slab

MYCIL

TRADE MARK

The B.D.H. Non-Mercurial Fungicide

Mycil is indicated in the treatment of fungal infections of the skin and particularly in athlete's foot.

By the combined use of Mycil Ointment and Mycil Dusting Powder clinical cure is effected; and the dusting powder used alone prevents reinfection.

Hepolon is produced by special processes which conserve all the known haematopoietic principles of the whole liver. It approximates to the extract described by Gänsslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anaemia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the haematonic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

Ampoules of 2 c.c. box of 6, 6 c., box of 12, 11 c., and box of 24, 22 c.
Rubber-capped vial of 10 c.c., 5 c., and of 33 c.c., 12 c.

HEPOLON

Contains in 100 c.c. the total soluble extract—measured of 2.0 g. fresh liver

Undecylenic Acid in the treatment of fungous infections of the skin

THE STUDY of possible fungicidal agents in sweat led to the use of naturally occurring fatty acids in therapeutics.

It has been found that undecylenic acid and its derivatives are among the most effective fungicidal agents, especially valuable in the prophylaxis and treatment of tinea pedis and other dermatophytoses.

Fungicidal Ointment-Boots contains 5% undecylenic acid and 20% zinc undecylenate in a vanishing cream base. Fungicidal Powder-Boots contains 2% undecylenic acid and 20% zinc undecylenate in a starch and kaolin base. They do not irritate the skin and may be used safely by patients for self-treatment over long periods.

Fungicidal Ointment-Boots

Tubes of approx. 1 oz.

Fungicidal Powder-Boots

Sprinkler containing approx. 2½ oz.

Watson X-Ray Apparatus **WORKS RELIABLY AND WELL**

Long experience has taught us how to make X-ray apparatus on which the user may rely implicitly. Electrically and mechanically, it is built for continuous use under all climatic conditions with the minimum of interruption for maintenance.

Radiologists throughout the world specify Watson equipment certain in the knowledge that it embodies the best features of contemporary design.

We will gladly submit proposals for the layout of modern X-ray departments on request.

of sausage meat is used, without any attempt at cleaning it, for cutting slices of corned beef. The corned beef is then placed on the weighing-machine plate, which quite normally in a butcher's shop is covered with blood. The corned beef is next, in some cases, wrapped in a small piece of grease-proof paper and placed on top of the raw meat, but in other cases it is placed in direct contact with the raw meat.

The recent Ministry of Food Circular MF5/48, "Cysticercus in Meat," is in my opinion of minor importance compared with the procedure stated above. Most, if not all, raw meat in this country is cooked before consumption by human beings, but cooked corned beef supplied to make up the meat ration is not usually recooked. If parasitic worms or cysts are present in the meat, offal, sausage, etc., and evade the meat inspector during inspection, they will be transferred to the corned beef by knives, by butchers' hands, by the scales, and by contact with the raw meat. In 1941 it was proved after the outbreak of trichiniasis in Wolverhampton that this disease was endemic in the Black Country. I consider that the Ministry of Food and the Ministry of Health should give careful consideration to the serving of cooked corned beef.—I am, etc.,

IAN NICHOLAN.

Dystocia after Amputation of Cervix

SIR.—With reference to Dr. Robert S. C. Fergusson's letter (Feb. 5, p. 241) and Mr. Walter Calvert's memorandum (Jan. 8, p. 58), I believe that the extensive scarification of the cervix resulting from trachelorrhaphies, and even amputations, done so often for chronic endocervicitis associated with milder degrees of lacerations, can be avoided by resort to the operation known here as the Sturmdorf procedure or tracheloplasty. This is fully described in American textbooks on gynaecology, and involves the cutting out of a conical segment of the cervix, extending if necessary to the level of the internal os. The diseased and infected tissues are thus effectually eliminated and the greater portion of the circular muscular fibres retained. There is little or no scar tissue left to impede adequate dilatation in subsequent pregnancies. I have delivered many women subsequent to this operation without difficulty.

Unfortunately the operation is not well known abroad, but may be recommended in appropriate cases as a way to avoid the dystocia described by your correspondents.—I am, etc.,

New York, N.Y.

GEO. W. KOSMAK.

POINTS FROM LETTERS

Temperature Recording

Mr. H. J. RAYNER (London, W.1) writes: As one of the students who performed some of the experiments summarized by Professor Samson Wright (April 9, p. 610) perhaps I might suggest that the common practice in recording temperatures is not so misleading as he indicates. He points out that a thermometer inscribed "half-minute" or "two minutes" will not accurately record the blood temperature when kept in the mouth (or axilla or groin) for the time indicated. He also suggests that it is undesirable to have a mark at 98.4° F. (36.9° C.) on clinical thermometers, because the "normal" temperature varies greatly with individuals and with external conditions. The experiments performed do certainly show this to be true, but as regards the clinical assessment of an abnormal temperature they may not be of great importance. In the surgery, the home, or the hospital a "half-minute" thermometer is normally placed in the mouth for one minute, or in the groin or axilla for two minutes, and a reading of over 98.4° F. is then generally considered to be above normal. The reading may not be the same as that of blood temperature, and perhaps if it were then a reading of 100° F. (37.8° C.) might not necessarily indicate pyrexia, but it is a reading taken under fairly standard conditions, and both the doctor and the layman have some idea of what such a reading is worth. I think that a further fact shown by the series of experiments was that in most people in health the average figure was lower than 98.0° F. (36.7° C.)—even when a thermometer was held in the mouth until a steady reading was obtained. For this reason any reading above the "normal" mark on the thermometer could be considered as abnormally high, except late in the evening. Personally I should favour retaining both the "half-minute" or "two minutes" inscription and also the mark at 98.4° F., because I think that a reading above this mark obtained in the time indicated does show an abnormal temperature.

Obituary

A. E. BARCLAY, O.B.E., M.D., F.R.C.P.

Dr. A. E. Barclay, who died at Oxford on April 26, was one of the outstanding figures in the world of radiology. Barclay of Manchester, as he was often known, though the later years of his life were spent at Oxford, was interested in every aspect of radiology. His special subject was the radiological study of the alimentary canal, on which he published papers as early as 1912. He was too young to be one of the original founders of the Roentgen Society, but he can be said to have belonged to the second rank of pioneers, eagerly interested in the rapidly opening field of radiology in the early decades of this century. He was one of those who saw the necessity for ensuring that those who set out to use x rays in medicine had the proper background of knowledge and the required standard of skill in the interpretation of what they saw. Barclay had much to do with the establishment of training courses in radiology and with the integration of this new discipline in the medical curriculum. He played an important part in the setting up of the diploma in medical radiology and electrolgy at Cambridge, which he himself took in 1921, and for which he was examiner for many years. His voice was heard more and more often in the counsels of radiologists in those early years. In 1919 he was elected president of the Electrotherapeutic Section (now the Section of Radiology) of the Royal Society of Medicine. He was president of the Roentgen Society in 1924, and, after the reorganization, president of the larger body, the British Institute of Radiology, in 1931. His work was recognized beyond the confines of this country, as attested by his honorary fellowship of the American College of Radiology and his honorary membership of many radiological societies in the Dominions and elsewhere. It was not only his scientific ability which brought him to the front rank, but also his attractive personality and his readiness on all occasions to help colleagues and juniors.

Alfred Ernest Barclay was born in Manchester on Sept. 30, 1876. He went to the Leys School, Cambridge, and from there to Christ's College. His clinical years were spent at the London Hospital, and he graduated in 1904. He was house-surgeon and clinical assistant in the aural and skin departments at the London Hospital, and it was probably his assistantship in the electrical department there and in the Finsen light department which aroused his interest in radioactivity. Barclay proceeded M.D. in 1912, and many years later, in 1937, he was incorporated D.M. at Oxford. In 1935 he became a member, and six years later was elected a fellow, of the Royal College of Physicians. Early in his career he returned to Manchester, where he became a consultant in radiology in private practice and honorary radiologist to the Manchester Royal Infirmary, with charge also of the x-ray department at Ancoats Hospital. He was appointed lecturer in radiology to Manchester University, and later held a similar position at Cambridge. The Nuffield Institute for Medical Research was established at Oxford in 1935 for the study of clinical, physiological, pharmacological, and anatomical problems by means of radiological and allied techniques, and Barclay was appointed honorary radiologist, serving also for a time during the war as acting director of the Institute. Here he collaborated in some important work with Trueta and others. It was in 1946 that Trueta, Barclay, and their colleagues demonstrated the renal shunt which may carry such a high proportion of the arterial blood into the renal vein that the cortex is left too anaemic to function properly. Subsequently, in spite of his serious illness, Barclay continued this work and applied the same technique of microradiology of injected blood vessels to the study of the human stomach. In collaboration with F. H. Bentley he was able to show what appears to be the same type of arterio-venous shunt in the gastric submucosa. Their work on this subject was published as recently as February of this year.

During the first world war Barclay served as a captain, R.A.M.C., and during the second world war he was consultant adviser on radiology to the Ministry of Health, and travelled all over the country inspecting hospital departments. His published work was chiefly on the application of x rays to the study of the abdominal viscera. In 1912, with W. J. S. Bythell,

a fellow radiologist of Manchester, he published *X-ray Diagnosis and Treatment*, for many years a standard textbook on the subject. *The Digestive Tract: A Radiological Study of its Anatomy, Physiology, and Pathology* appeared in 1933, and there was a second edition in 1936. He was the author of many other publications in British and foreign medical journals. In 1920 at Cambridge, and again in 1930 at Melbourne, he was president of the Section of Radiology at the B.M.A. Annual Meeting.

Barclay had been chosen to deliver the Mackenzie Davidson Memorial Lecture under the auspices of the British Institute of Radiology in March, 1949, but when the time came he was far too ill to do so, and the Institute as a mark of respect to him met only for formal business, arranging no other event to take the place of the expected lecture. Its president travelled to Oxford to present him with the lecturer's medal, and brought back a story of a long and painful illness most bravely and cheerfully borne. It was characteristic of Barclay that within two days of his second operation he was sitting up in bed tracing out on paper exactly what the surgeons had done to him. The university of his native Manchester intended to confer on him the honorary degree of D.Sc. on founder's day, May 18. The D.Sc. of Oxford was conferred on him in 1947. In 1946 he was made an honorary member of the Liverpool Medical Institution, and on that occasion the public orator described Barclay as one of the pioneers who had helped to build "a well-fitted dark-room in the house of Medicine." He went on: "Once upon a time he was a Manchester man, but he has long lived that down in the genial air of Oxford. He has given us the work of a master in his book on the radiology of the digestive tract. . . . To craftsmanship he adds a scholar's integrity. He has always taught that the study of the normal is the beginning of radiological wisdom. . . . As Socrates felt about words, so he feels about x-ray shadows. To use them in the improper sense is not only a bad thing in itself, but it also generates a bad habit in the soul."

Dr. S. Cochrane Shanks writes: Others will tell the story of Alfred E. Barclay's life. I want to record some aspects of his character that won for him his outstanding reputation as a radiologist and the affection and regard of all who knew him. Barclay was a man irrepressibly good-humoured and benign. It was impossible for a normal individual not to like him. As a consultant adviser in the E.M.S. during the last war he was inevitably subject to occasional ill-informed criticism. I well remember his reaction to one vicious letter: that of sympathetic concern for the state of mind of the writer. It simply didn't occur to him to take offence, and the charm of his personality rallied the radiologists of the country round him when he organized the x-ray services of the E.M.S. His success in that task was due also to two other qualities—imaginative enthusiasm and untiring industry; qualities which were also responsible for his deserved reputation as a young radiologist at Manchester and as a researcher in the last phase of his life. The generation who knew Barclay only as a doyen may not appreciate how much he contributed to the radiology of the alimentary tract. His two early books on that subject, published in 1912 and 1914, are classics of their time. In them there is much that is now quaint, but much more that was new then and has stood the test of time. That Barclay, an able young man with an inquiring mind, should contribute to the knowledge of a new and growing subject is not so very remarkable. Many young men have done the same. What is remarkable is that he should, after the age of 60, re-enter the field of research and, in the Nuffield Laboratories at Oxford, lead a team in a series of brilliant anatomical researches on the foetal circulation and on hitherto unknown vascular shunts in the kidney and stomach. Very few have done that. Indeed, alike in youth and in age, he flamed into recurrent brilliance, and radiology is the richer for his long and active life.

SIR SIDNEY SEWELL, M.D., F.R.C.P., F.R.A.C.P.

Sir Sidney Sewell, one of the best-known physicians in the State of Victoria, died on March 13. The prominent part he took from 1928 to 1938 in the formation of an Association of Physicians of Australasia, which led finally to the foundation of the Royal Australasian College of Physicians, will long be remembered. He was Vice-President of the College from 1938 to 1940 and President from 1940 to 1942.

After a brilliant undergraduate career Sidney Valentine Sewell completed his medical course in 1905 and graduated at the head of his year with first-class honours in medicine, surgery, and obstetrics, sharing the exhibition in medicine with G. C. M. Mathieson and winning the exhibition and the Beane Scholarship in surgery. He was appointed senior resident medical officer to the Royal Melbourne Hospital in 1906, and clinical assistant to medical out-patients in 1910, after his return from two years' postgraduate work in England and Germany. Sewell's public hospital work was almost exclusively confined to the Royal Melbourne Hospital. He became physician to out-patients in 1911, and when he retired in 1939, after nearly thirty years of unremitting service, he was made consulting physician to the hospital. Like many of the senior men, he returned to full duty in the wards during the recent war. Sewell obtained his M.D. in 1910. He became a foundation fellow of the Royal Australasian College of Physicians in 1938, and in 1939 was elected F.R.C.P. He was knighted in 1945.

Sewell's ambition was to follow in the footsteps of his guide and friend, the late Sir Richard Stawell. Sir Richard had set a high standard of medical teaching in Melbourne, based on the best English tradition and practice. Sewell followed his example and never spared himself or his students. His teaching at the bedside will not easily be forgotten by medical practitioners now scattered over all the States of the Commonwealth. The first world war of 1914-18 always held painful memories for Sewell. Owing to a persistent infection following an acute attack of appendicitis in early manhood, his health from his early student days was far from robust. It was remarkable that he subsequently accomplished so much in spite of this constant handicap. He volunteered for active service in the war, but, after more than one medical examination, acceptance for military service overseas was refused on the ground of unfitness. This was a severe blow to him. He served at home and was particularly successful in his treatment of "shell-shocked" cases.

Sir Sidney Sewell had been interested for more than twenty-five years in the management and treatment of tuberculosis. His proclaimed aim was a constructive scheme to wage war against tuberculosis in Victoria so as to stamp it out within a defined number of years. He endeavoured by every means in his power to obtain the co-operation of Federal and State Governments together with the understanding and sympathetic assistance of the community in general. Sewell fought vigorously and uncompromisingly against what he considered to be the apathy, ignorance, and inertia of Government departments on this subject. His crusade was not popular in official circles and it earned him some enmity. He was ultimately effective, however, in arousing general interest in this most difficult problem. He took up vigorously the question of money allowances for public patients during their stay in sanatoria. Here he was in advance of his time in recognizing that often when medical treatment was refused by patients, or its acceptance delayed, the reason was financial. He also insisted that treatment when it was accepted lost much of its beneficial effect if the family breadwinner carried with him into the sanatorium anxieties about the financial welfare of his family. Sewell fought strenuously for adequate monetary allowances for these patients, and was rewarded with a considerable measure of success. During the last few months of his life Sir Sidney was recognized by the State Government of Victoria as its unofficial adviser and consultant on questions connected with pulmonary tuberculosis. Official recognition of his work has also been made in the decision to establish "The Sir Sidney Sewell Pathological Wing" in the new sanatorium for 400 male patients, to be erected at any early date at Watsonia, near Melbourne.

Sir Sidney Sewell died from a malignant growth of the lung, which was diagnosed several months before his death. Knowing all the facts, he determined to put his affairs in order and to die in harness. During the final three months, and under increasing difficulties, he was true to his ideals and continued to work for the better management of tuberculosis. Sir Sidney was in the first flight of physicians in Australasia. His knowledge was extensive, his intellectual grasp of medical problems was profound, and he kept well abreast of all major developments in his subject. Many patients and colleagues will mourn his passing and miss his inspiring help in time of need.—C. V. M.

C. W. M. HOPE, O.B.E., M.D., F.R.C.S.

Mr. C. W. M. Hope, consulting surgeon for diseases of the ear, nose, and throat to King's College Hospital, London, died at his home in Knaresborough on April 21 at the age of 68. A memorial service was held at the Hospital Chapel on Monday, May 2.

Charles William Menelaus Hope was educated at Clifton College and the University of Durham, where he graduated M.B., B.S. in 1903. He took the F.R.C.S. in 1908, and proceeded M.D. a year later. After holding three resident appointments at the Royal Infirmary, Newcastle-upon-Tyne, he came to London in 1908, where at first he was resident anaesthetist at St. Mary's Hospital and then clinical assistant to Mr. William Hill in the ear, nose, and throat department. Hope was registrar and later assistant surgeon to the Throat Hospital, Golden Square. In 1914 he was appointed to the honorary staff of King's College Hospital as assistant surgeon for diseases of the nose and throat under the late Sir St. Clair Thomson. He became the first head of the combined nose and throat and aural departments in 1932, and remained in charge until his retirement in 1941. He was also consulting surgeon to the Finchley Memorial Hospital and the Royal Eye Hospital, Southwark.

Mr. Hope served in the two world wars. In the 1914-18 war he was a surgeon with the rank of major, R.A.M.C., attached to the St. John Ambulance Brigade Hospital, B.E.F. For his services he was awarded the O.B.E. and was made an officer of the Order of St. John of Jerusalem. At the outbreak of the second world war he at once joined the Emergency Medical Service as a full-time surgeon, and he was posted to Horton Emergency Hospital, Epsom, where he worked until continued ill-health led to his retirement in 1941.

Hope was a very fine operator, and all who worked with him, whether as students, residents, clinical assistants, or registrars, will always remember his kindness, thoroughness, and patience, and his meticulous attention to every detail affecting the welfare of his patient, whether in the out-patients department or the theatre. Until ill-health compelled him to slow down, he was a hard and conscientious worker, and though he did not write a great deal he gave a fine training to all who worked under him, and set an example to students and junior staff that they will always remember. He was interested in all the students' activities of King's College Hospital Medical School, and was associated with the Students' Club and Societies Union for nearly twenty years, first as secretary and later as president. In this work he came into close contact with the students, who always knew him affectionately as "Charlie Hope."

Outside medicine he had many interests, including fishing, gardening, and carpentry. He enjoyed using his hands, in play as well as in work, and no matter what he did he always did it thoroughly. He had a keen appreciation of values and always insisted on the best. His annual holiday was spent in the north of Scotland salmon fishing, and many friends will remember the fine fresh salmon which came to them in late June or early July from Brora. He was a bachelor whose kindness, generosity, and compelling personality ensured him a wide circle of friends. He will be greatly missed, though never forgotten, by all those who worked under him and learned so much from him.—T. C.

The Joint Committee of the Order of St. John of Jerusalem and the British Red Cross Society has issued its *Register of Ambulance Stations* listing the addresses and telephone numbers where ambulances may be obtained. The service covers many types of cases that do not fall within the ambit of the National Health Service.

Medico-Legal

DEATH FOLLOWING ABORTION

Verdict of Misadventure

At an inquest held at Slough on April 4 and April 13 evidence was given that the death of a girl of 19 was due to shock resulting from an operation for the induction of premature labour.

The mother of Marianne Elise Gotzky said her daughter had not told her that she was pregnant. One day her daughter had turned on the gas. Only after this incident did she confide in the mother, and she said that she would rather end her life than continue with the pregnancy. Her own father, an elderly medical man, arranged for her to take her daughter for examination by a psychiatrist. The psychiatrist had arranged for her to see Mr. Norman Haire and she had given Mr. Haire her own cheque for £150. After her daughter's death Mr. Haire sent her a cheque.

Dr. Ellis Stungo said that he saw Miss Gotzky on three occasions. She was so distressed and unbalanced that he felt she might make another attempt at suicide. He came to the conclusion that her pregnancy should be terminated, and he accepted full responsibility for having advised this. He suggested to the mother that the case was one which would be dealt with by any hospital, but that if she wished he would make arrangements for the girl to be operated on as a private patient. He said that he was paid 12 guineas for these consultations. So far as he knew there were no ill effects following skilled therapeutic interference. It was impossible to treat a patient by psychotherapy in such circumstances. The treatment was the removal of the cause of her symptoms. She could have been admitted to a mental hospital, but he would not have advised that.

Evidence was then given by the night nurse at the Parkside Nursing Home, Upton Court Road, Slough, and by the matron of the home, who explained that she had no certificates and her knowledge of nursing had been acquired by experience. Miss Gotzky was admitted on the evening of April 1 and the operation was performed the following morning. As a general rule, the matron said, she received her fees from the patients, but in this case her account for £7 18s. was paid by Mr. Haire.

The anaesthetist, Dr. Oswald Stuart Thompson, said that the patient was given thiopentone intravenously. He then administered gas and oxygen and a minimum quantity of trileone. The operation took ten or fifteen minutes. He was dismantling his apparatus and packing it away when he noticed that the patient had changed colour and was gasping for breath. Pure oxygen, coramine, and adrenaline were administered, and finally adrenaline was injected into the heart muscle, but without effect. Artificial respiration was continued for probably three-quarters of an hour. The patient had recovered from the anaesthetic to the extent that she was trying to push the airway from her mouth, and her laryngeal reflexes had returned.

Mr. Norman Haire, who reported the death to the coroner, said there was some uncertainty about the period of pregnancy. He judged that the patient was approaching the 28th week and it seemed possible that the child might be saved. For that reason he took good care not to rupture the membranes before injecting the paste. It was extremely rare for shock to take place in connexion with these operations. He said that he did "quite a lot of this kind of work—more than the average gynaecologist."

Findings at Necropsy

Dr. Keith Simpson reported that at necropsy the most careful routine examination failed to reveal any evidence of organic disease of any kind. There was no deformity or disproportion of the pelvis likely to interfere with the normal termination of a full-term pregnancy. A seven-months gestation was present and in a healthy state, capable of continuation to term. The cervix had been dilated and a gelatinous paste introduced, separating the sac of the pregnancy for about an inch around the internal orifice of the neck of the womb. There was no pulmonary embolism and only the slightest bleeding had occurred. The entire absence of any organic cause of death

gave proper grounds for the inference that death was due to reflex shock. Shock would not reflect lack of skill in the procedure, but light anaesthesia in an emotional subject would predispose to it. In his opinion the cause of death was shock due to artificial abortion. It would have been perfectly easy to deliver this child alive by immediate operation on the apparent death of the mother. It was viable in law, having reached the 28th week, and his examination revealed no reason to suppose that it was not alive in the uterus.

Shock was a well-recognized possible consequence of either dilating the cervix or of injecting any substance into the uterus. Death in such cases was quite sudden, unheralded, and might ensue within a few seconds. He thought it was remotely possible, but unlikely, that death did not take place until ten minutes after the operation, as had been suggested by the matron. There was no evidence that what had been done had not been done skilfully. There were facilities in any general hospital for performing such operations if they were necessary. This could come under the National Health Service without cost to the family of the patient.

The jury returned a verdict of misadventure in accordance with the medical evidence and added a rider recording its opinion "that decisions to undertake operations of this type should be more strictly safeguarded, and such operations should be carried out only in State hospitals under the National Health Scheme."

Medical Notes in Parliament

LONDON CENTRE FOR TROPICAL MEDICINE

Mr. IVOR THOMAS on April 27 recalled how in 1898 Mr. Joseph Chamberlain, Sir Patrick Manson, and Sir Percival Nairne had founded at the Albert Dock Hospital the London School of Tropical Medicine. Manson's idea was that teaching, treatment, and research should be carried on by one organization in one group of buildings. When the first world war ended, the Hospital for Tropical Diseases was established in Gordon Street, and the school was reopened there in 1920. In 1924 the school was merged in the London School of Hygiene and Tropical Medicine. This separated teaching from the treatment of tropical diseases, but nevertheless Britain maintained a high place in both teaching and treatment until the outbreak of the second world war. The building in Gordon Street then had to be closed because it was unsuitable as a hospital under threat of air attack. A little later a land mine fell behind it. It then became necessary to consider what provision should be made after the war, and in April, 1941, Lord Moyne appointed an interdepartmental committee to go into the question. After the end of the war a temporary hospital was opened in Devonshire Street. Good work had been done there and the staff had rendered devoted service, but accommodation was very limited, and no one would claim that the hospital was an adequate centre. He thought there should be set up in London a comprehensive hospital for tropical diseases with the status of a post-graduate teaching hospital and with its own board of governors. It should be erected within the curtilage of the University of London to be close to the London School of Hygiene and Tropical Medicine. It would probably cost £1,000,000, but nothing short of such a scheme would meet the need.

Mr. Bevan had told him on Feb. 10 (*Journal*, Feb. 19, p. 328) that it was proposed to develop a tropical diseases centre as a unit of the University College Hospital group. What was wanted was a tropical diseases hospital with 150 beds and an outpatient department of the polyclinic type.

Dr. HADEN GUEST said Mr. Thomas was out of touch with the present difficulties in regard to staffing. Anything like the scheme Mr. Thomas suggested was out of the question at present.

Dr. STEPHEN TAYLOR said, as a comparatively recently appointed governor of University College Hospital, that the collection of tropical cases was a practical difficulty. Until recently places in the existing temporary hospital were nothing like filled. This was due in part to the fact that many medical officers and specialists had had experience in the Forces of the treatment of tropical diseases and were anxious to use that experience in treating cases in non-tropical disease hospitals and general wards in London. On behalf of the governors of University College Hospital he assured Mr. Thomas that their desire was to see a worthy tropical diseases hospital and unit developed as part of that hospital. The governors hoped the

new location of the tropical diseases hospital would be in the old St. Pancras Hospital not much farther away from the University of London than the old building was.

Mr. BLENKINSOP, replying to the debate, said everybody desired proper provision in London for the treatment of tropical diseases and the teaching of tropical medicine. After the report of the interdepartmental committee had been submitted a decision was taken that instead of going forward on the line then suggested, which was out of keeping with the development of the National Health Service, it would be preferable not to develop a completely isolated and separate hospital but to have a separate unit in close association with one of the large teaching hospitals. In accordance with that decision the Devonshire Street Hospital had been associated with the University College Hospital group. It was true that the accommodation at Devonshire Street was too crowded, although some very good equipment was available and very valuable services had been given there. It was proposed to improve the facilities by adding a more adequate inoculation centre. The proposal now being considered by the University College Hospital group would provide a considerable unit distinct from but at the same time associated with St. Pancras. The suggestion was that a modern block could be utilized there which would have the facilities of a great hospital by its side. The Ministry hoped a decision would be reached on this soon. Quite properly University College Hospital must have regard to other factors. If this accommodation was used for tropical medicine other plans must be re-examined. But, after seeing both premises and meeting some of those concerned, Mr. Blenkinsop was satisfied that University College Hospital was as anxious as was the Ministry to ensure that proper facilities should be available as rapidly as possible. As it became possible to undertake larger building projects larger schemes could be undertaken. He thought the proposal under consideration would meet immediate needs adequately.

Beds Not in Use

Mr. BEVAN said on April 28, replying to Colonel STODDART-SCOTT, that the number of beds closed for want of staff in hospitals in Great Britain on Dec. 31, 1948, was 59,903, made up as follows:

Tuberculosis sanatoria	..	5,669
Fever hospitals	..	15,915
General hospitals	..	21,642
Other specialized institutions	..	16,677
		<u>59,903</u>

Colonel Stoddart-Scott further asked how much of the £15,000,000 required to staff and maintain these 60,000 hospital beds had been included in Mr. Bevan's estimates for the coming year.

Mr. Bevan said the annual budgets of the hospital management committees did not specify separately anticipated expenditure on the reopening of closed beds, so that he was unable to give the information desired.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

On April 23 the degrees of M.B., B.Chir., were conferred on Muriel E. Sidaway.

A Pinsent-Darwin Studentship has been awarded to John McFie, M.B., B.Chir.

A course in paediatrics and obstetrics will be held at Addenbrooke's Hospital, Cambridge, from May 16 to 27. Eleven half-day sessions will consist of lectures and demonstrations. Details of the course, the number attending which is limited, may be obtained from the secretary, the Medical School, the Naval Hut, Downing College, Cambridge.

UNIVERSITY OF BIRMINGHAM

Professor E. B. Verney, F.R.S., Sheild Professor of Pharmacology in the University of Cambridge, will deliver the William Withering Lectures in the Anatomy Theatre of the Medical School of the University on May 12, 13, 16, and 17, at 4 p.m. His subject is "The Excretion of Water by the Kidney, with Special Reference to its Neurohypophyseal Control."

The Ingleby Lectures will be delivered by Mr. Charles D. Read, Director of Postgraduate Studies, Chelsea Hospital for Women, in the Anatomy Theatre of the Medical School of the University on May 19 and 26, at 4 p.m. His subject is "The Problems of Stress Incontinence of Urine in the Female."

Members of the medical profession and students of medicine are invited to attend the lectures.

No 15

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 16

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland
Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland
A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1949					1948 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London (administrative county)) will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county) are combined.

| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Typhoid Fever at Crowthorne

The diagnosis of typhoid fever was confirmed on April 30 in a patient admitted to the Royal Berkshire Hospital from Crowthorne, which has a population of 3,500. During the next two days the diagnosis was confirmed in four other patients, and a total of 32 persons were suspected of suffering from the disease. The earliest of the dates of onset so far mentioned is April 21. The usual steps have been taken by way of prevention and control, but in any event an outbreak of considerable magnitude is to be expected. It cannot be assumed that the disease will remain confined to Crowthorne until the source and vehicle of infection have been identified.

Crowthorne is at the junction of the territory of three regional hospital boards: North-west Metropolitan, South-west Metropolitan, and Oxford. Cases are known to have been admitted to hospital at Winchester as well as at the Reading hospital. The organism has been identified as Vi-phage Type E1.

Smallpox

The last of the eleven cases of smallpox imported on the s.s. *Mooltan* was removed to hospital on April 16. The period of surveillance of the numerous contacts with these cases has now expired without notification of the disease in any of them. Although there is reason to hope that the infection has not passed to anyone in this country it is too early to exclude the possibility of a missed case, because at least one of the patients may have been in contact with persons who could not be brought under surveillance. Special vigilance should therefore continue for a further two or three weeks.

Fortunately the passengers and crew of the s.s. *Mooltan* gave the public health authorities helpful co-operation. The persons who developed the disease were removed early and before they could do much damage. With very few exceptions contacts accepted vaccination promptly and remained under surveillance. The several public health departments concerned, particularly those for the ten districts in which the imported cases were taken ill, appear to have carried out the routine measures for the control of smallpox without a hitch.

The patients who survived are now making satisfactory progress, and the case fatality, 6 out of 12, is unlikely to alter. In two patients modification by previous vaccination had reduced the disease to a triviality, varicella virus was recovered, however, on egg culture. Virus was also recovered from the remaining cases except the one at Liverpool.

Future Population Trends

The birth rate during 1948 was 17.9 per 1,000 and 2.7 below the post-war peak of the preceding year. Except for 1946 and 1947, however, this rate was the highest since 1922. The rise in the birth rate following the war was apparently of a temporary nature and was not, as has been suggested, due to a permanent increase in the average size of families. The effective reproduction rate corresponding to the births which occurred in 1948, after making allowance for a continuing improvement in the likelihood of survival, has been provisionally assessed at 1.070. With present trends this rate will fall during the next year or so to below 1.0, which is the level of replacement. The marriage rate at 18.1 remained fairly high. From 1921 to 1937 this rate varied between 14.3 and 17.5. The maintenance of a high marriage rate means that the birth rate may remain above the level of the years immediately preceding the war.

A forecast by the Registrar General based on the present trends, suggests that in 1960 there will be 22.3% of the population under the age of 15 and 12.1% aged 65 and over, compared with 21.4% and 10.7% in 1948. The school population will be at its peak, and with the present trends a decline must be expected after this date. On the other hand the number of pensioners will continue to increase and become proportionately more important, placing a gradually increasing burden on the social services.

Notifications During First Quarter

In the first thirteen weeks of this year whooping-cough and acute pneumonia have been unusually prevalent, and so has measles. The fall in the incidence of diphtheria has continued, and the notifications were only one-quarter of the number recorded four years ago and about one-fourteenth of the number recorded in the first thirteen weeks of 1938. Notifications of dysentery and of cerebrospinal fever were the lowest of recent first quarters. The incidence of acute poliomyelitis showed a considerable improvement on the preceding year but remains above the pre-epidemic level. The number of deaths

attributed to influenza in the great towns was higher than in recent first quarters. The figures for the first quarters of the past five years were as follows:

England and Wales	1945	1946	1947	1948	1949
Scarlet fever ..	19,163	16,952	15,527	23,348	16,087
Whooping-cough ..	19,780	20,033	27,922	35,034	37,221
Diphtheria ..	6,061	6,220	2,832	2,466	1,523
Measles ..	247,455	17,652	165,895	88,489	201,140
Acute pneumonia ..	14,782	16,278	15,500	10,969	17,147
Cerebrospinal fever ..	968	906	1,110	629	479
Acute poliomyelitis ..	61	104	114	381	224
Dysentery ..	4,681	4,444	931	2,100	886
Enteric (typhoid and paratyphoid fevers)	140	138	98	103	100
Great Towns Influenza deaths ..	693	2,156	1,335	272	2,278

Discussion of Table

In England and Wales infectious diseases were less prevalent during the week, and there were decreases in the incidence of measles 1,658, whooping-cough 341, acute pneumonia 362, scarlet fever 152, and dysentery 14.

Large decreases in the notifications of measles were recorded in Southampton 213, Lancashire 150, Hertfordshire 138, London 118, and Essex 111; the chief exception to the general decline was an increase of 109 in Middlesex. There was a fall in the incidence of whooping-cough in every area except in London and the south-eastern counties, where an increase of 39 in the notifications was reported.

An outbreak of diphtheria affected 8 persons in Berkshire, Wokingham R.D., and there was an increase of 9 in the notifications in Staffordshire. A small decrease was recorded in the notifications of scarlet fever in most areas, the largest exceptions to the general trend being rises in Lancashire 15 and Yorkshire 11. A fall in the incidence of acute pneumonia was general throughout the country.

The chief centres of infection for dysentery were Lancashire 11 (Liverpool C.B. 8) and Yorkshire West Riding 13 (Huddersfield C.B. 11).

In Scotland there was a rise of 9 in the incidence of diphtheria, and there were falls in the notifications of measles 87, whooping-cough 72, scarlet fever 31, and acute primary pneumonia 31. Dysentery reappeared in Edinburgh, where 8 cases were notified during the week. In Glasgow the notifications of dysentery fell from 20 to 5.

In Eire decreases were recorded in the notifications of scarlet fever 35, whooping-cough 32, and diarrhoea and enteritis 21. These changes were mainly due to the experience of Dublin C.B.

In Northern Ireland decreases were reported in the notifications of whooping-cough 31 and measles 21. In contrast to the general trend, increases in the notifications of measles were reported from Belfast C.B. 10 and County Antrim 11.

Week Ending April 23

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 953, whooping-cough 95, measles 13,514, acute pneumonia 759, 34, acute poliomyelitis 8, dysentery 52, typhoid 7, and typhoid 3. Deaths from influenza in the great towns numbered 51.

The Services

DEATHS IN THE SERVICES

Surgeon-Lieutenant JOHN MICHAEL ALDERTON, R.N., was killed in action in H.M.S. *Amethyst* on April 20. Born at Colchester on Oct. 19, 1924, he came of a medical family, his father, grandfather, and great-uncle all being members of the medical profession. He was educated at Epsom College, having gained the Leverhulme Scholarship there in 1938. On leaving Epsom he won a scholarship at University College Hospital, London. After graduating M.B., B.S. in 1946, he held the post of casualty officer at the British Postgraduate Medical School, Hammersmith. John Alderton was commissioned in the Royal Navy in September, 1947, and sailed for Hong Kong to join H.M.S. *Amethyst* in the following January. Outside medicine his two main interests were music and yachting. He was a keen member of the United Hospitals Sailing Club. He also played hockey for University College. He was of a naturally shy disposition but had a lovable character and keen sense of humour. All who knew him well will not be surprised that he merited the high tribute paid to him by the Admiralty: "He moved round the ship unflinchingly, aiding the wounded until he himself was killed." Our sympathy goes out to his parents and younger brother.—M.H.C.

Medical News

Dr. Douglas Fairley

Dr. Douglas Fairley has been appointed a Nominated Member of the Executive Council of the Island of St. Helena.

Dr. John Gillies

Dr. John Gillies, one of the doctors in attendance on the King at his recent operation, has been appointed a Commander of the Royal Victorian Order.

Spectrographic Research Unit

By arrangement with the London Hospital, the Medical Research Council has established there a Spectrographic Research Unit under the direction of Dr. E. R. Holiday. The primary function of the unit is to undertake original research work in the field of absorption spectrophotometry as applied to biological problems of medical interest, but advice and assistance will also be given to other branches of the Council's organization using such methods. The unit has been based on the spectrographic department originally established by the London Hospital, and during the last five years partly supported by the Council for the purposes which are now being developed.

Invitation from Professor C. R. Marshall

An invitation is extended to all members of the class of *material medica* at Aberdeen University from 1919 to 1930 inclusive who are attending the B.M.A. Meeting in Harrogate to a dinner at the Troutbeck Hotel, Ilkley, on Friday, July 1, at 7 p.m. Buses from Harrogate will be provided. Those wishing to accept should write, saying if accompanied by a lady, to Professor Marshall, Annisholme, Manor Park, Burley-in-Wharfedale, Yorkshire, before June 7.

Lecturing in Italy

Dr. Margaret Tod, Deputy Director of the Holt Radium Institute, Manchester, is visiting Italy between May 5 and 21 to meet Italian radiotherapists in preparation for the International Radiological Congress to be held in England in 1950. She will also lecture for the British Council in Milan, Bologna, Florence, and Rome on "Cancer Organization and Our Clinic System" and "Accurate Dosage in Radium and X-ray Therapy."

Royal Commission on Capital Punishment

Dr. Eliot Slater has been appointed a member of the Royal Commission on Capital Punishment. The following are the other members: Sir Ernest Gowers (chairman), Mrs. E. D. C. Cameron, Mr. N. R. Fox-Andrews, K.C., Miss Florence Hancock, Mr. William Jones, Mr. Horace Macdonald, Mr. John Mann, Sir Alexander Maxwell, Professor G. A. Montgomery, K.C., Lord Peel, Professor Leon Radzinowicz. The secretary is Mr. F. L. T. Graham-Harrison, of the Home Office. The terms of reference of the commission are: To consider and report whether liability under the criminal law in Great Britain to suffer capital punishment for murder should be limited or modified, and, if so, to what extent and by what means; for how long and under what conditions persons who would otherwise have been liable to suffer capital punishment should be detained, and what changes in the existing law and the prison system would be required; and to inquire into and take account of the position in those countries whose experience and practice may throw light on these questions. Those wishing to give evidence should apply to the secretary, submitting a written statement of the evidence which they wish to give. Communications should be addressed for the present to the secretary, Royal Commission on Capital Punishment, Home Office, Whitehall, London, S.W.1.

Control of Tropical Diseases

In accordance with proposals agreed to by the Economic Co-operation Administration in Washington to aid development of certain areas in the British Empire, Dr. Frederick J. Brady, of the U.S. Public Health Service, and Mr. Harry H. Stage, of the U.S. Department of Agriculture, will visit Africa to study the control of trypanosomiasis and malaria. They will leave New York on May 10, and after consulting the Colonial Office in London will visit East and West Africa, will survey the conditions there, and make recommendations on further U.S. assistance in combating the tsetse fly and mosquito.

Aftercare of Delinquents

The Home Secretary has approved the establishment of a Central Aftercare Association for England and Wales to supervise persons released from Borstal training, corrective training, and preventive detention, and young prisoners released on licence. The Borstal Association, the Aylesbury Aftercare Association, and the Central Association for the Aid of Discharged Convicts are to be merged in it.

Streptomycin under Marshall Aid

The Economic Co-operation Administration has stated that streptomycin to the value of £2,500,000 has been provided under Marshall Aid for the treatment of tuberculosis in Europe. E.C.A. funds are also financing the reconstruction of two French plants to produce the drug.

Soap for Bedridden Patients

On the recommendation of his medical advisers the Minister of Food has decided that bedridden patients who suffer also from a condition for which extra soap is granted may receive both the special allowance of soap appropriate to their condition and the one extra ration of soap to which they are entitled because they are bedridden. Doctors are asked, when authorizing extra soap for their bedridden patients, to write the word "bedridden" on the R.G.50 and not quote the classification of this condition in MED.2 (Revised 1948). If a bedridden patient also qualifies for soap under another classification in the MED.2 (Revised 1948), that classification should be quoted and the word "bedridden" added to it, so that extra soap can be made available to the patient on both counts. Patients whose condition requires the liberal application of ointments, pastes, or similar preparations qualify for one extra soap ration a week. They must present at the Local Food Office a medical certificate stating that soap is required for that reason.

Director of Army Health

The title of Director of Hygiene at the War Office has been changed to Director of Army Health. The titles of Deputy Directors, Assistant Directors, and Deputy Assistant Directors have been changed similarly. Specialists in Hygiene are now entitled Specialists in Army Health. The present Director of Army Health is Brigadier A. E. Richmond.

Association of Independent Hospitals

The independent hospitals and kindred organizations—by which is meant hospitals, convalescent homes, epileptic colonies, and other institutions that have either been disclaimed from, or were not transferable under the Acts to, the National Health Service—have formed an Association of Independent Hospitals and kindred organizations. Its objects are to safeguard and develop the interests of these hospitals, which are the remaining voluntary hospitals of the country and therefore are wholly dependent on the public and on themselves for maintenance.

Peruvian Academy Honours Medical Historian

At a special meeting of the Peruvian Academy of Surgery held in Lima on Feb. 11 Dr. Douglas Guthrie, lecturer on the history of medicine in the University of Edinburgh, who has been acting as visiting professor to the University of San Marcos, was admitted to the honorary membership of the Academy. Dr. Guthrie is the first British surgeon to receive this distinction, which was accompanied by the presentation of an enamel badge bearing the emblem of the academy, the spade-shaped knife or "tumi" which was used by the Incas for their primitive trephining operations.

World Federation for Mental Health

The first number of the *Bulletin* of the World Federation for Mental Health has been issued as a successor to the series of twelve bulletins distributed by the International Congress on Mental Health held in London last year. The *Bulletin* is intended to serve as a link between the Federation and member associations in different countries. It is also intended for the exchange of ideas and information on the principles and practice of mental health throughout the world. In each issue it is proposed to publish at least one original article on some topic relevant to the Federation's work. It may be obtained for 5s. a year (post free) from the editor, at the World Federation for Mental Health, 19, Manchester Street, London, W.1.

Blockaded Berlin

An official pamphlet, *Notes on the Blockade of Berlin, 1948*, touches on the public health problems of the blockaded area. So 8,652 undernourished children have been flown out to the Western zones by the British air lift. The first medical supply to be flown was ether, which had formerly come from the Eastern Zone. A number of patients have been removed from hospitals to the Western zones so that the beds in Berlin may be used so far as possible for cases of serious or acute sickness. The chief types of cases treated are those requiring specialized treatment unavailable in Berlin or a long rest and good food, and cases of early and fulminating tuberculosis and of convalescent poliomyelitis.

Acknowledgment for War Service

The President of the Czechoslovak Republic has conferred the ration of Chevalier of the Order of the White Lion upon Drs. or Macdonald Walker, O.B.E., and Thomas Forrest Cotton in recognition of services rendered during the war.

Aberdeen Children's Welfare Council

At a recent conference at Aberdeen of organizations whose principal objects include the care of children it was decided to form a Children's Welfare Council. It will help to correlate the work of the various bodies concerned with child care in all its social aspects. Professor John Craig, of the Department of Child Health, Aberdeen University, is chairman, and Mr. Auld, of the Association of Social Service, is secretary.

Wills

Dr. Theodore Shennan, Regius Professor of Pathology at Aberdeen University 1914-36, left £4,561. Dr. Herbert John Pulling, of Brighton, left £37,909; Dr. Archibald Deane, formerly of Eastbourne, £18,907; Dr. Frederick Henry Healey, formerly medical superintendent of Hellesden Mental Hospital, £4,226; and Lieut.-Col. Henry Smith, late I.M.S., £57,240.

COMING EVENTS

Royal Society Lectures

The Bakerian Lecture for 1949 will be delivered on May 12 by Professor H. Raistrick, F.R.S., Professor of Biochemistry at London University. The Croonian Lecture for 1949 will be delivered on June 30 by Dr. D. W. Bronk, Foreign Member of the Royal Society. Dr. Bronk is Foreign Secretary of the National Academy of Sciences and Chairman of the National Research Council of the U.S.A. The Wilkins Lecture for 1949 will be delivered on Dec. 15 by Professor E. N. da C. Andrade, F.R.S., Quain Professor of Physics at London University.

National Industrial Safety Congress

The Royal Society for the Prevention of Accidents will hold the National Industrial Safety Congress on May 13-15 at Scarborough. It is open to non-members as well as members. Speakers include Sir Geoffrey King, Deputy Secretary at the Ministry of National Insurance, and Sir Charles Bartlett, managing director of Vauxhall Motors Limited. Particulars may be obtained from the Industrial Safety Division of the Royal Society for the Prevention of Accidents, 131, Sloane Street, London, S.W.1.

Lectures on Psychology

The Institute for the Scientific Treatment of Delinquency has arranged a course of eight lectures on "Selected Topics in Psychology" to be given by Miss Gertrude Keir, M.A., at the Institute, 8, Bourdon Street, Davies Street, London, W., on Thursdays, commencing May 26, at 6.30 p.m. The lectures are intended for students who have some basic knowledge of elementary psychology, and the fee for the course is 10s. Those wishing to attend should make early application to the Education Secretary.

Charities Ball

A Charities Ball organized by the Metropolitan Counties Branch of the B.M.A. will be held at B.M.A. House, Tavistock Square, London, W.C.1, on Thursday, May 26, at 8 p.m. for 8.30 p.m. The proceeds will be devoted to medical charities in urgent need of support. Patrons include the President of the Association and the Presidents of the three Royal Colleges. There will also be a cabaret and facilities for bridge. The cost of tickets including a buffet supper is two guineas each. Applications should be sent to the Secretary, the Charities Ball Committee, Metropolitan Counties Branch, B.M.A. House. Contributions to charities from those unable to attend the ball would also be most welcome and should be sent to the same address.

Tuberculosis Meeting at Liverpool

A joint meeting of the British Tuberculosis Association and the North-Western Tuberculosis Society will be held at the Medical Institution, Mount Pleasant, Liverpool, on Friday and Saturday, May 27 and 28. The programme is as follows: May 27, 2 p.m., Sir Henry Cohen, "Tuberculosis and General Medicine"; 2.45 p.m., discussion on "Domestic Treatment of Pulmonary Tuberculosis," to be opened by a representative of the British Tuberculosis Association, followed by Dr. R. Heller and Dr. C. H. C. Toussaint; 4.45 p.m., discussion on "Tuberculosis in Seamen," to be opened by Dr. R. N. Walker; 5.45 p.m., extraordinary meeting of British Tuberculosis Association; 7.30 for 8 p.m., informal dinner at Reece's Restaurant, Parker Street, Liverpool. May 28, 9 a.m., general meeting of British Tuberculosis Association; 9.15 a.m., demonstration of a series of cases of pulmonary tuberculosis treated by the more recent developments of surgery, as follows: "Thoracoplastic Operation using the Polythene Pack," by Mr. H. Morrison Davies and Mr. Leslie J. Temple, and (1) "Periosteoplastic Pneumonolysis" and (2) "Lung Resection," by Mr. F. Ronald Edwards; 10.45 a.m., "Rehabilitation in Surgical Tuberculosis," by Mr. J. P. Heron; 12 noon, colour film, "Surgical Treatment of Tuberculous Epididymitis" (by courtesy of Mr. J. Cosbie Ross).

SOCIETIES AND LECTURES

Monday

- EDINBURGH UNIVERSITY.—At Physiology Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, May 9, 5 p.m., "The Prehistory of Medicine," by Dr. Douglas Guthrie.
- LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, W.C., May 9, 4.45 p.m., "Selective Toxicity with Special Reference to Chemotherapy," by Professor Adrian Albert.
- MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—May 9, 8 p.m., annual general meeting; 8.30 p.m., "Temperament," Annual Oration by Mr. A. C. Palmer.
- WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At Royal Society of Medicine, 1, Wimpole Street, London, W., May 9, 8.30 p.m., Cavendish Lecture: "The Contribution of Law to Literature," by The Rt Hon Mr Justice Birkett.

Tuesday

- CHLSEA CLINICAL SOCIETY.—At South Kensington Hotel, Queen's Gate Terrace, London, S.W., May 10, 7 for 7.30 p.m. Annual dinner.
- INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 10, 5 p.m., "The Sclerodermas," by Dr. C. B. Dowling.
- INSTITUTE OF LARYNGOLOGY AND OTITIS, 330, Gray's Inn Road, London, W.C.—May 10, 2.15 p.m., "The Respiratory Tract in Infectious Diseases," by Dr. E. H. R. Harries.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 10, (1) 11 a.m., "Serological Tests in the Diagnosis of Syphilis," by Dr. R. Thomson; (2) 5 p.m., "Genito-urinary Tuberculosis, I," by Mr. F. J. F. Barrington.
- LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., May 10, 5.30 p.m., "Some Advances in Chemotherapeutic Research at the Pasteur Institute," by Professor Jacques Tréfouel (Pasteur Institute, Paris).
- LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, W.C., May 10, 5.15 p.m., "Physiological Properties of Ethyl Alcohol," by Dr. M. Grace Eggleston.
- WRIGHT-FLEMING INSTITUTE OF MICROBIOLOGY, St. Mary's Hospital Medical School, Paddington, W.—May 10, 5 p.m., "Biochemical Properties of the Bacterial Cell Wall," by Dr. E. F. Gale.

Wednesday

- GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—May 11, 8 p.m., "Pupillary Movements," by Dr. Fergus Campbell.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 11, (1) 11 a.m., "Biological False-positive Reactions for Syphilis," by Dr. R. Thomson; (2) 5 p.m., "Calculous Disease of the Kidney and Ureter, I," by Mr. H. P. Winsbury-White.
- SOUTH-WEST LONDON MEDICAL SOCIETY.—At Bolingbroke Hospital, Wandsworth Common, S.W., May 11, 8.30 p.m. Seventh meeting of session in conjunction with Wandsworth Division of B.M.A. Subject: Demonstration of cases by the honorary medical staff of Bolingbroke Hospital.

Thursday

- BIRMINGHAM UNIVERSITY.—At Anatomy Theatre, Medical School, Birmingham, May 12, 4 p.m., "The Excretion of Water by the Kidney with Special Reference to its Neurohypophyseal Control," William Withering Lecture by Professor E. B. Verney, F.R.S.
- DURHAM UNIVERSITY.—At Royal Victoria Infirmary, Tyne, May 12, 5.15 p.m., "The Morison Disease," Fifth Rutherford Morison Lecture by Dr. H. P. Saint (Capetown).
- EDINBURGH UNIVERSITY.—At Anatomy Theatre, University New Buildings, Teviot Place, May 12, 5 p.m., "Medical Aspects of Splenectomy," Honyman Gillespie Lecture by Dr. H. N. Robson.
- INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—May 12, 5 p.m., "Anogenital Pruritus," by Dr. B. Russell.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., May 12, (1) 11 a.m., "Congenital Syphilis," by Dr. S. M. Laird; (2) 5 p.m., "Genito-urinary Tuberculosis, II," by Mr. F. J. F. Barrington.
- ROYAL SOCIETY, Burlington House, Piccadilly, London, W.—May 12, 4.30 p.m., "A Region of Biosynthesis," Bakerian Lecture by Professor Harold Raistrick, F.R.S.
- ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—May 12, 4.30 p.m., "Psychiatry," lecture-demonstration by Dr. D. Curran.

Friday

- BIRMINGHAM UNIVERSITY.—At Anatomy Theatre, Medical School, Birmingham, May 13, 4 p.m., "The Excretion of Water by the Kidney, with Special Reference to its Neurohypophyseal Control," William Withering Lecture by Professor E. B. Verney, F.R.S.
- LONDON UNIVERSITY.—At King's College, Strand, W.C., May 13, 5.30 p.m., "Heart Metabolism and Coronary Disease," by Professor K. L. Gollwitzer-Meier (Hamburg).
- ROYAL MEDICAL BENEVOLENT FUND.—At Medical Society of London, 11, Chandos Street, Cavendish Square, W., May 13, 5.15 p.m., 113th general meeting.

Saturday

SOUTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At Royal Sea Bathing Hospital, Margate, May 14, clinical session, presided over by Dr. B. W. Armstrong, followed by luncheon at Nayland Rock Hotel, Margate.

APPOINTMENTS

MIDDLEMISS, J. H., M.D., D.M.R.D., F.F.R., Director of Radiodiagnostic Department, United Bristol Hospitals.

Dr. Middlemiss graduated at Durham University in 1940 and proceeded M.D. in 1947. He was formerly Assistant Radiologist at the Royal Victoria Infirmary, Newcastle-upon-Tyne, and is the author of several papers on radiodiagnosis.

Dr. James A. Doull, Medical Director, U.S. Public Health Service, has been appointed Medical Director of the Leonard Wood Memorial (American Leprosy Foundation). Dr. Doull succeeds Dr. H. Windsor Wade, who, because of ill health, has been relieved of administrative duties and appointed associate medical director. Dr. Wade will continue his pathological studies at Culion, Philippine Islands, and the editorship of the *International Journal of Leprosy*. The headquarters of the medical department of the Memorial has been transferred from Culion, P.I., to 1832 M Street, N.W., Washington 6, D.C., U.S.A.

BAIRD, MISS EVA CRICHTON, M.B., Ch.B., D.P.H., Assistant Medical Officer, Burgh of Hamilton, Lanarkshire.

FAY, IRO, M.D., D.P.H., Deputy County Medical Officer, Somerset County Council.

LAWSON, T. O. P. D., M.B., Ch.B., D.Obst R.C.O.G., D.P.H., Medical Officer of Health and School Medical Officer, County Borough of Dudley.

PARKER, W. S., M.B., Ch.B., D.P.H., D.I.H., Deputy Medical Officer of Health County Borough of Brighton.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

- Armin.—On April 18 1949, to Dr. Margaret Armin (née Conway), wife of Dr. Richard Armin, a third daughter.
- Brownlee.—On April 1, 1949, at Edinburgh, to Margot, wife of T. J. Brownlee F.R.C.S. Ed., twin sons.
- Glanvill.—On April 10, 1949, at Maternity Wing, General Hospital, Sunderland, to Dr. Catherine Glanvill, wife of Dr. Terry Glanvill, a daughter.
- Green.—On April 25, 1949, to Drs. Mildred and Norman Green, of Stoke-on-Trent, a son.
- Risby.—On April 19 1949, at Lewisham, to Joan, wife of Dr. J. P. V. Risby, a daughter.
- Woodruff.—On April 25, 1949, at the Middlesex Hospital, London, W. to Helen, wife of Dr. A. Waller Woodruff, a daughter.
- Yeates.—On April 3, 1949, at Newcastle-upon-Tyne, to Mr. and Mrs. W. Keith Yeates, a daughter.

MARRIAGES

- Gordon-Harris-Wright.—On April 23, 1949, at St. George's, Hanover Square, London, W., Ian James Gordon, M.B., Ch.B., Aberdeen, to Pamela Nonette Harris-Wright, M.B., B.S., M.R.C.S., L.R.C.P., London.
- Thomson-Mowat.—On April 14, 1949, at Heath Congregational Church, Halloway, George William Rosslyn Thomson, M.B., B.S., to Mary Stewart Mowat, M.B., Ch.B.

DEATHS

- Barclay.—On April 26, 1949, at Oxford Alfred Ernest Barclay, O.B.E., M.D., D.Sc., F.R.C.P., of Oxford and Manchester.
- Churchill.—On April 23, 1949, Joseph Henry Churchill, M.R.C.S., L.R.C.P., of Byland House, Cleveland Walk, Bath.
- De'va.—On April 21, 1949, at Fielden House, London Hospital, Joseph De'va, M.D., of Hatherley House, Central Park Road, East Ham, E 6.
- Halliday.—On April 18, 1949, at Highlands, Lacey Green, near Princes Risborough, Bucks, John Rutherford Halliday, M.D.
- Hocken.—On April 16, 1949, at 8, Tremena Road, St Austell, Cornwall, Melville Hocken, M.B., B.S., formerly of Halesworth, Suffolk.
- Hodson.—On April 18, 1949, at his home, Snarebrook, Bergholt Road, Colchester, Essex, Howard Bluntham Hodson, M.D., D.P.H., aged 42.
- McKertrick.—On April 14, 1949, Frederick John McKertrick, M.B., C.M. Ed., of Dane View, Danbury, Chelmsford, Essex, aged 84.
- Melville.—On April 14, 1949, at Millbank Military Hospital, London, S.W. very suddenly, Charles William Francis Melville, C.B., M.B., Ch.B. Ed. Major-General I.M.S., Ret., aged 72.
- Neilson.—On April 13, 1949, at Woking, Surrey, Henry John Neilson, C.B.F. M.D., aged 86.
- Pattison.—On April 9, 1949, at 39, Montpelier Villas, Cheltenham, Blanche Sutton Pattison, M.R.C.S., L.R.C.P., aged 52.
- Panson.—On April 12, 1949, at Dyserth, Flintshire, Edward Basil Panson, M.B., B.Chir.
- Pench.—On April 5, 1949, at Palmerston North, New Zealand, Charles William Pench, M.B., C.M., aged 76.
- Richards.—On April 18, 1949, at Downes, Monkleigh, Bideford, Devon, Owen William Richards, C.M.G., D.S.O., M.Ch., F.R.C.S.
- Sewell.—On March 13, 1949, Sir Sidney Valentine Sewell, M.D., F.R.C.P., F.R.A.C.P., of Victoria, Australia.
- Syme.—On April 14, 1949, at Barnellan, Bardowie, Stirlingshire, William Smith Syme, M.C., M.B., Ch.B., F.R.F.P.S. Glas.
- Turner.—On April 17, 1949 (Easter Day), at Ty Newydd, Ruabon, North Wales, Annie Catharine (née Lyon), the faithful and beloved wife of Dr. A. H. Turner, and mother of Arthur and Isabel.
- Warner.—On April 20, 1949, at Royal Devon and Exeter Hospital, Harold Percy Warner, M.B., B.S., of Rydal, Woodford Green, Essex, aged 63.
- Wills.—On holiday at St. Helier, Jersey, James Robertson Wills, M.B., B.Ch. aged 46.

for the treatment of
HAYFEVER

'Benadryl'

It has been found possible to control the symptoms of hayfever in many patients by the oral administration of 'Benadryl.' This potent histamine antagonist is also invaluable for those who have not had time to acquire complete tolerance to grass pollen after desensitizing courses with pollen extract.

One 50 mgm. capsule of 'Benadryl' taken when hayfever symptoms first appear often gives relief for from three to five hours. Subsequent dosage depends on the response of the patient and on the prevailing atmospheric conditions. For infants and children Elixir 'Benadryl' or 25 mgm capsules are available.

Capsules : (25 and 50 mgm.) in bottles of 50 and 500
Elixir : In bottles of 4 and 16 fluid ounces

An important advance in Antisepsis

Streph is an important advance in antisepsis, being non-selective in action and effective against a wide range of pathogens.

Its activity is maintained in the presence of proteins and it is non-necrotic, non-toxic and non-staining.

It is miscible with water, normal saline and alcohol. Streph is a powerful deodorant and approximately

three times as effective as Liq. Chloroxenolis or lysol.

These advantages make Streph the better antiseptic for medical, surgical and obstetrical use.

STREPH

THE BETTER ANTISEPTIC

two important aids in infant care

BABY LOTION — for nappie changing and skin irritation

BABY POWDER — for use after every bath

Johnson's Baby Lotion for the routine care of infants' skin has already received wide medical support. A smooth, white, antiseptic oil-in-water emulsion, it reduces effectively surface bacteria, urine irritation, and other types of rash. Together with Johnson's Baby Powder, these are two important products every mother needs in the care of her baby.

Johnson & Johnson

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED SLOUGH AND GARGRAVE

JELONET is an improved non-adhesive, open-mesh dressing evenly and thoroughly saturated with petroleum jelly and 1 per cent Balsam of Peru. It is sterilized ready for use. When used as a dressing for shallow wounds or skin grafts its unique 'ventilating' character provides optimum conditions for the delicate epithelium or transplanted graft. Jelonet is obtainable in tins containing 36 cut pieces ($3\frac{1}{2} \times 3\frac{1}{2}$) or 8 yd. continuous strips.

THE POTENT NATURAL OESTROGEN

'PROGYNON' B OLEOSUM

(OESTRADIOL MONOBENZOATE
FOR INJECTION)

'Progynon' B Oleosum, by intramuscular injection, provides complete oestrogen replacement therapy with absence of toxic effects. It exerts a beneficial psychological action which is not found in treatment with synthetic oestrogens. Presented in strengths of 1 mg. (10,000 International Benzgate Units), and 5 mg. (50,000 International Benzgate Units), 'Progynon' B Oleosum is indicated in all conditions associated with oestrogen deficiency, such as the menopause, hypomenorrhoea, amenorrhoea, certain forms of dysmenorrhoea, oligomenorrhoea, etc. For local therapy, in atrophic vaginitis, kraurosis vulvae, etc. 'Progynon' Ointment and Vaginal Suppositories are available.

Painless INTRAMUSCULAR INJECTIONS

e.g. of **PENICILLIN, LIVER EXTRACTS,
ARSENO-BENZOLS, BISMUTH, etc.**

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructible to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made
immediately before use **ONLY**.

NOVUTOX
*Self-Sterilising
Local Anaesthetic*

Each cc. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

First Aid for Carbolic Poisoning

Q.—What first-aid treatment should be given in cases of poisoning by phenol and by cresol antiseptics?

A.—The object of first-aid treatment in poisoning by phenol or related antiseptics must be to evacuate from the stomach as much of the ingested poison as possible and so prevent or minimize its absorption and its local effects. The main form of first-aid treatment is therefore gastric lavage. Repeated large quantities of lukewarm water should be used until the washings are free from the smell of carbolic. This end-point may be difficult to determine, as the operator, often working in an atmosphere laden with the smell of carbolic, will fail to detect by smell the relatively faint traces of the substance in the later washings. After this repeated lavage one of the reputed antidotes may be introduced into the stomach—for example, magnesium sulphate or sodium sulphate, 1 oz. (31 g.), or sugar of lime, $\frac{1}{2}$ oz. (15.5 g.), in half a pint (284 ml.) of lukewarm water. The value of these substances is not satisfactorily established, however, and in any case they should be removed from the stomach after an interval of 10 to 15 minutes, and renewed if considered advisable. Alternatively, white of egg in milk may be administered, or liquid paraffin, either of which may be of some use in diminishing absorption and protecting the alimentary mucosa. If the respiration is failing, artificial respiration should be maintained and respiratory and cardiac stimulants can be injected. Caffeine and fluids may be given by rectum. The administration of fluids intravenously is of value but can hardly be considered a first-aid measure.

It must be emphasized, however, that the feature of first-aid treatment most likely to be of substantial value is the prompt evacuation of the poison before absorption and severe local necrosis have taken place. Too much must not be expected from the routine use of any known antidote. It should be remembered that carbolic is absorbed through the skin and also by inhalation. Where the skin surface has been contaminated the area should be thoroughly cleansed, and for this purpose alcohol is recommended.

Intravenous Saline in Intermittent Claudication

Q.—What is the rationale of the use of intravenous hypertonic saline in cases of intermittent claudication? Has this method of treatment proved of any value in cases with arterio-sclerotic changes?

A.—Intravenous injections of hypertonic saline have been used widely in the treatment of intermittent claudication, whether due to thrombo-angiitis or to arterial degeneration. Temporary benefit has often been reported. The effect is thought to be produced by suddenly increasing the blood volume and thus promoting vasodilatation, which favours the collateral circulation in the affected limb. The results obtained with saline are transient, and the method has fallen into disuse because it was often necessary to infuse a litre daily. Promising results were reported with plasma transfusion, but enthusiasm was damped when several patients developed homologous serum jaundice.

Serological Diagnosis of Whooping-cough

Q.—To what extent can the serological diagnosis of whooping-cough be relied on? What recorded experiences are there bearing on this subject?

A.—Various methods have been used to demonstrate the presence of specific antibodies in the blood of patients with whooping-cough. These antibodies develop rather late in the course of the infection, usually from the third week onwards, and are therefore of little value for early diagnosis. The two methods which have been most commonly used in this country are the complement-fixation test and the agglutination reaction.

In a child a positive reaction to the complement-fixation test in a dilution of 1 in 4 or more of the patient's serum, using a killed culture of *Haemophilus pertussis* as antigen, is very suggestive of infection. The agglutination reaction is more variable and requires a fresh living culture for its performance. In the U.S.A. the opsonocytaphagic reaction and a mouse test for protective antibody are also used. British references to the use of the complement-fixation test and agglutination reaction in pertussis are, respectively, Donald, A. B., *British Medical Journal*, 1938, 2, 613; and Evans, D. G., and Maitland, H. B., *J. Path. Bact.*, 1939, 48, 468.

Teaching Writing to the Left-handed

Q.—Is there any standard method of teaching writing to the left-handed child? I know that such children should not be forced to use the other hand for writing, as this may lead to stammering or other forms of hesitancy.

A.—In teaching left-handed children to write, the following method has been found useful: (1) Place the paper slanting to right, not left. (2) Hold the pencil $\frac{1}{2}$ to 2 inches (3.75 to 5 cm.) from the point, so that the hand does not block the view of what is being written. (3) Train the child to visualize beforehand what he is going to produce, as he would if drawing an object. (4) To encourage the movement from left to right, start by using both hands at the same time, making circles and strokes. Practise slope towards right. (5) Write from a copy, very slowly and carefully, beginning with repeated single letters and without lifting the pencil from the paper. (6) Develop ambidexterity in other skills, such as woodwork and games.

It is very important to avoid fatigue and hurry. Exercises should be carried out slowly and for short periods. The mechanical difficulties of left-handers are sometimes made worse by the anxiety of feeling an oddity, so this should of course be avoided so far as possible. It may be useful to stress the fact that the left-handed cricketer or tennis-player may confound his opponents by his sinister dominance.

Burning Buddleia

Q.—When old Buddleia wood was burned in the garden I noticed a sweetish smell in the air and was affected in the nose and chest (I am a hay-fever subject). Not only did I sneeze, but I was rendered heavy and drowsy and "queer in the head." What particular ethereal oils or alkaloids in the tree would cause these reactions?

A.—Hypersensitivity to odours of plant origin has often been recorded as a cause of asthma and rhinitis. Thus asthma may occur in carpenters working with the wood of coniferous and other trees. With regard to *Buddleia*, however, no record can be found in the standard botanical reference books of any ethereal oil or alkaloid occurring in any species growing in this country. A Mexican species—*Buddleia perfoliata*—has leaves which contain an oil with a peculiar but pleasant odour, due apparently to the presence of fatty aldehydes. This species, so far as is known, is not in cultivation in this country.

Weight Increase in Pregnancy

Q.—What is the normal gain in weight of a pregnant woman, and what are the limits of normal variation? How is the increase accounted for?

A.—The gain in weight during normal pregnancy is subject to wide variation, but for practical purposes is generally reckoned as 24 ± 10 lb. (10.9 ± 4.5 kg.). According to L. G. Chesley (*Amer. J. Obstet. Gynec.*, 1944, 48, 563) two-thirds of normal women gain between 13 and 35 lb. (5.9 and 15.9 kg.) but one-sixth more than 35 lb. The total increase in any one case, however, is to some extent dependent on the woman's initial bulk, and Stander, H. J., and Pastore, J. B. (*ibid.*, 1940, 39, 928), suggest that it should not exceed 25% of the pre-pregnancy weight. There are, however, many exceptions even to this. The gain does not take place regularly throughout pregnancy. In the first three months there is often little change, and even a loss may be recorded, especially when the woman has vomiting or anorexia. In the last two or three weeks there is also a tendency to lose, or to cease to gain, weight, probably as a result of increased fluid excretion. It has been said that at no time should the monthly increase exceed 5 lb. (2.26 kg.), otherwise

it may indicate occult oedema and the threatened onset of toxæmia. In fact this sign is quite unreliable, and there may be a gain of as much as 10 lb. (4.5 kg.) in any one month without the development of toxæmia.

The increase in weight is accounted for by: full-term child, 7½ lb. (3.4 kg.); liquor amnii, 2½ lb. (1.1 kg.); placenta, 1 lb. (0.45 kg.); enlargement of uterus, 2 lb. (0.9 kg.); breast development, 3½ lb. (1.58 kg.); protein retention not included under other items, 4 lb. (1.8 kg.); increase in blood volume, 3½ lb. (1.58 kg.); while the remainder is due to fluid retention in the tissues and a general deposition of fat.

Sterilizing Skin before Injection

Q.—What do you consider the best method of sterilizing the skin before immunization?

A.—For sterilization of the skin before subcutaneous or intramuscular injection of antitoxin, toxoid, or vaccine used in passive or active immunization a quickly acting disinfectant is needed, and preferably one which stains the skin so that the sterilized area can readily be seen. For this purpose tincture of iodine, or 1 to 2% iodine in 70% alcohol, is undoubtedly the most effective, since it sterilizes the skin in the least time it takes to dry—about 15 to 20 seconds. The skin should not be previously washed. Alternatively, 70 to 80% alcohol by itself may be used; absolute alcohol and methylated spirit are much less effective. Some cationic detergent preparations like "cetavlon" or "zephiran" are also quickly effective if used in 70% alcohol. The mercurial preparations, antiseptic dyes, hypochlorite, ether, and "dettol" have a slower or otherwise imperfect disinfecting action on the skin.

Hyoscine Hydrobromide for a Child

Q.—Is it safe to give hyoscine hydrobromide to a child of 23 months? If so, in what dosage? The child in question is always travel-sick, and is shortly going to Ireland.

A.—It would be quite safe to give hyoscine hydrobromide to a child of 23 months. A suitable dosage would be 1/400 gr. (0.16 mg.) half an hour before sailing, and a second 1/400 gr. at sailing time.

Disturbed Micturition in Disseminated Sclerosis

Q.—Can you suggest any treatment to counteract precipitancy and frequency of micturition in a case of disseminated sclerosis?

A.—The precipitancy and frequency of micturition in disseminated sclerosis arise, of course, from interference with the pathways concerned with the higher control of the bladder reflexes. As the cause is the actual damage to or loss of these fibres, medical treatment is of necessity disappointing. Theoretically, decrease in sensation of the bladder will improve the complaint, but this is difficult to attain, and the nearest approach to it is the use of sedatives, which the patient has probably already tried. Any infection, ill-health, or deterioration in general well-being makes these symptoms worse, and therefore should be prevented if at all possible. Limitation of fluid intake within reasonable limits also helps. Atropine has been used, but is disappointing.

Toxicity of Phenobarbitone

Q.—I am interested in the toxic reactions to phenobarbitone (soluble). What symptoms have been reported so far? What effect, if any, has it on the appetite?

A.—Most of the reported cases of phenobarbitone poisoning by ordinary doses have occurred in people who have an idiosyncrasy to the drug. The most frequent symptoms have been various types of skin eruptions, often accompanied by fever, mental disturbances, and sometimes nausea, gastric pain, and diarrhoea. There is much variation in the central nervous symptoms, which include delayed effects, extreme depression, excitement, and sometimes even mania. As with alcohol, there is a certain amount of habituation, but little real tolerance develops, and withdrawal reactions characteristic of morphine have not been observed. Prolonged use may lead to the development of psychical degeneration and nausea.

Its effect on appetite has been studied only in rats (M. R. Jones, *J. comp. Psychol.*, 1943, 35, 1). In these experiments

each rat received 80 mg. per kilo of body weight daily, which is large by human standards. During the first week the drugged rats ate more than the control animals; after the first week they ate less. Cessation of injections after the sixth week caused a drop in the food intake in the experimental but not in the control groups. This decrease in food intake may be permanent, for the lower rate of growth persists.

Treatment of Gout

Q.—What treatment is likely to benefit an active man aged 60 who has suffered for years from rheumatism and had his first attack of gout in the left big toe eight weeks ago? He has lived for some years in a hotel, and any request for a special diet, or any serious disability, would almost certainly result in his being asked to leave.

A.—The presumption in this case appears to be that all the patient's previous "rheumatism" has in fact been due to latent gout, which has at last declared itself in its true colours. With regard to treatment, this of course implies a permanent regimen, although this need not be made unduly difficult in this case, for the reasons given. The patient should, however, avoid alcohol, lead as quiet and regular a life as possible, with early bed, and feed on simple, plainly cooked food without condiments. He should endeavour to avoid "offal," such as liver, heart, kidney, etc., and should considerably increase his intake of non-alcoholic fluids, preferably between meals. If in the future he has an acute attack, it will be essential to put him to bed for a day or two. Even if it is possible for him to struggle along, it is more likely to become chronic if he does so. For one day he should be given cinchophen 7½ gr. (0.5 g.) thrice daily. During this period he should also start taking tab. colchicin, 1/64 gr. (1 mg.) hourly until he develops slight diarrhoea or vomiting; he should then drop the colchicine to one tablet thrice daily for two weeks. In the intervals between the acute attacks, as regards medicinal treatment (provided there is no contraindication, such as liver disease), he should continue one day every month (say, Sunday) on cinchophen for the next six months; if the cycle can thus be broken, he may then develop no further acute attacks.

NOTES AND COMMENTS

Spread of Tuberculosis by Books.—Dr. T. PETERSON (Plymouth) writes: With reference to the question and answer on the possibility of books handled by tuberculous patients carrying tubercle bacilli ("Any Questions?" April 2, p. 601), I was surprised to see the statement made in your answer: "Fortunately the bacilli become non-viable in about 48 hours when they are dry. . . ." Surely this is not in accord with accepted teaching. For instance, Muir and Ritchie (*Manual of Bacteriology*, 1937, London, p. 414) state that dried phthisical sputum has been found to contain virulent bacilli after two months. Another authority gives a life of ten days or more in road dust, or up to two months if kept in the dried state in the dark. The latter condition might well be found in an untreated library book. I may say that this question is of particular interest to me, since I have for some time been considering the problem of the provision of separate library facilities for tuberculous patients not in hospital.

Cause of Rib Fracture.—Dr. KEVIN BYRNE (Lakemba, New South Wales) writes: A patient—muscularly strong—owner of a dairy, used to collect as cow-feed waste cabbages from Sydney's "Paddy's Markets," tossing them on a large fork over a high-sided receptacle fitted to his lorry. One day a particularly heavy forkful slipped off as he started to toss. The anticipated exertion was used on the lightened load. Muscular effort alone accounted for six very badly fractured ribs, three on each side.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 7 1949

THE SECRETARY REPORTS

THE WORLD MEDICAL ASSOCIATION

In the week following Easter I was away in Spain attending the council of the World Medical Association. It may be of interest to members of the Association if I describe some of the work that this body is doing. But first a few words about its history. Before the war there existed a useful international body, the Association Professionnelle Internationale des Médecins, which provided a convenient medium for the exchange of ideas and information among the national medical associations of European countries. Towards the end of the war the need was felt for an even more comprehensive body which would not only continue and extend the work of the A.P.I.M. but would make available to the international governmental organization—the World Health Organization—the considered views of the profession. After preliminary conferences in London in July, 1945, and in September, 1946, at the latter of which 33 countries were represented, it was resolved to build upon the basis of the old A.P.I.M. a more ambitious body, to be called the World Medical Association, and a committee was appointed to prepare a constitution. In Paris in September, 1947, the constitution was approved and the first formal meeting of the assembly of the association was held. Over 40 countries were represented, and almost all of them have become members of the association. A council of 10 members, with *ex officio* members, was elected.

Objects of WMA

The assembly adopted the following as the objects of the association:

- (i) To promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available.
- (ii) To maintain the honour and protect the interests of the medical profession.
- (iii) To study and report on the professional problems which confront the medical profession in the different countries.
- (iv) To organize an exchange of information on matters of interest to the medical profession.
- (v) To establish relations with, and to present the views of the medical profession to, the World Health Organization, Unesco, and other appropriate bodies.
- (vi) To assist all peoples of the world to attain the highest possible level of health.
- (vii) To promote world peace.

The World Medical Association is supported partly by the subscriptions of its members—national medical associations of the different countries—and partly by a very generous annual donation from a mixed medical and lay committee in the United States of America. The headquarters was established in New York and Dr. Louis Bauer appointed secretary-general. In its first year the World Medical Association was necessarily preoccupied with problems of organization, though it managed to deal with at least two subjects of wide interest. The council met in New York in the spring of 1948, and prepared for the second general assembly, held in Geneva last year, a report on German war crimes and another giving information about the medical profession and forms of State medical provision in 23 countries. The Geneva assembly, like its predecessor, was well attended, and the British representatives included the Chairman of Council of the B.M.A. and the Chairman of the Representative Body.

Madrid Meeting

The Madrid meeting of the WMA council, which was attended by Dr. Pridham as a member of that body and by myself as president-elect, got down to a number of important problems

in preparation for this year's general assembly, to be held in London from Oct. 11 to 14. Following preparatory work by subcommittees, conducted by post, the council completed a report on the standards of medical education, an analysis of unqualified practice and such limitations as are applied to it, and a report on what we should call the patent-medicine problem. Both these reports embodying information from many of the countries of the world. In addition it approved, for report to the general assembly, a document in which the national health or social security schemes of 20 countries were analysed in relation to the principles adopted in Geneva last year.

A committee of the council, over which Dr. Cibré presides, is at present at work on a draft international code of ethics, and Dr. Pridham is chairman of a committee on postgraduate medical education.

My impression of the recent council meeting is that although its members come from different parts of the world, with all the difficulties of language which that involves, they have really begun to get down to problems of mutual concern and to collating information. Dr. Routley, secretary of the Canadian Medical Association, is chairman of the council, and its members are: Dr. Henderson, of the United States; Dr. Pridham, of Great Britain; Dr. Bustamante, of Cuba; Dr. Yui, of China; Dr. Sen, of India; Dr. Cibré, of France; Dr. Knutson, of Sweden; Dr. Glorieux, of Belgium; Dr. Tornel, of Spain; with, as *ex officio* members, Dr. Leuch, of Switzerland (treasurer); Professor Marquis, of France (president); and Dr. Hill, of Great Britain (president-elect). Every member of the council turned up, almost all having travelled by plane. The expenses of council meetings are met, as are the expenses of the New York office, from the moneys provided by the American committee. The expenses of delegates attending the general assembly are met by the member countries which send them.

The World Medical Association publishes a *Bulletin*, which is to appear quarterly. The first issue has just been published, and a copy of it will be sent in due course to members of Council, members of the Representative Body, to Division Secretaries, and to any individual practitioner who cares to send me a postcard.

Contact with WHO

One of the most interesting reports made to the Madrid council meeting was that of its observer at the World Health Organization, Dr. Maystre, of Geneva. From what he said it is clear that, just as the British Medical Association needs to maintain a close if somewhat critical association with the Ministry of Health, so the profession throughout the world needs, through the World Medical Association, to maintain close touch with what is a purely governmental body—the World Health Organization. For the most part the World Health Organization consists of governmental representatives, although it is significant that in the case of the United States, Canada, and India the governments have thought fit to include in their delegation practitioners not in governmental employment. While the World Health Organization meets for weeks at a stretch, the World Medical Association can meet only twice a year, once in assembly and once in council, and the need for its existence—if only to maintain this liaison—is becoming pretty clear.

The present position can perhaps be best summed up by saying that, thanks to some very enthusiastic workers and America's generosity, the World Medical Association has made a good start and has begun to get down to some very useful work, not the least of which is the preparation of factual reports describing and comparing what is going on in different parts of the world in a number of fields, including the relations between the profession and the State.

National Health Service

REGIONAL ORGANIZATION OF MINISTRY OF HEALTH

The Ministry's regional organization has been adjusted to meet the changed circumstances due to the National Health Service Act and the National Assistance Act. The Minister has transferred the functions of the principal housing officers to principal regional officers, who are working in the regions. They are assuming full regional responsibility for the housing work and carrying out (with the help of public health nursing officers, welfare officers, and other regional staff) the duties previously performed by general inspectors and the regional officers for health services, whose appointments as such will be ended.

The principal regional officers have no executive functions in relation to regional hospital boards, hospital management committees, boards of governors, executive councils, or local health authorities. They collaborate with the regional medical officers in the regions and maintain close contact with these boards and committees in order to exchange information and keep the Minister informed of local developments over the whole range of the health services. They also exercise the powers of inspection prescribed by the National Assistance (Powers of Inspection) Regulations, 1948.

Principal Medical Officers

The functions of the principal regional officers are complementary to those of the principal medical officers, who work on the basis of hospital regions and operate mainly from Whitehall. In general a principal medical officer deals with a group of three regional hospital boards and with the local health authorities and local authorities wholly or mainly within those regions. Each has a small team of nurses and medical officers working under him. The names of the principal medical officers and their medical staff are as follows:

Newcastle, Leeds, and Sheffield Hospital Regions.—Principal Medical Officer: Dr. G. Lilico. Medical Officers: Maj.-Gen. A. D. Fraser (at Newcastle R.O.); Dr. K. M. Hirst; Dr. Johnstone Jervis (at Leeds R.O.); Maj.-Gen. R. W. D. Leslie (at Nottingham R.O.); Dr. D. M. Lyon.

East Anglian, N.W. Metropolitan, and N.E. Metropolitan Hospital Regions.—Principal Medical Officer: Dr. A. L. Banks. Medical Officers: Dr. R. M. Shaw; Dr. C. Sims-Roberts; Dr. D. S. Todd-White.

S.E. Metropolitan, S.W. Metropolitan, and Oxford Hospital Regions.—Principal Medical Officer: Dr. G. E. Godber. Medical Officers: Dr. M. Manson; Dr. A. E. Martin; Dr. A. L. Winner.

South-Western Hospital Region.—Principal Medical Officer: Dr. J. Ferguson. Medical Officers: Dr. R. Elliott; Dr. C. Grant Nicol.

Manchester and Liverpool Hospital Regions.—Principal Medical Officer: Sir Alexander Hood. Medical Officers: Dr. M. G. Gorrie; Dr. J. M. Ross (at Manchester R.O.).

Birmingham Hospital Region.—Principal Medical Officer: Dr. G. A. Clark. Medical Officer: Dr. C. A. Seeley (at Birmingham R.O.).

ANAESTHETICS FOR DENTAL OPERATIONS

The Ministry of Health has issued a statement on payments for giving anaesthetics for dental operations. An anaesthetist on the staff of a hospital who assists a dentist holding a hospital appointment does the work as part of his hospital services and does not receive a fee from the dentist. A general practitioner holding an appointment at a general-practitioner hospital solely for the purpose of giving general medical services would receive payment from the dentist when the dentist holds no hospital appointment but is treating an in-patient in a general-practitioner hospital where such facilities have been given by arrangement with the management committee. However, if the general practitioner is on the staff of the hospital as an *anaesthetist* he would not receive a fee.

Where the patient is in a private pay-bed by private arrangement with the dentist and has not been accepted by the dentist under Part IV of the Act: if the anaesthetist is a whole-time officer of the hospital board or management committee and not entitled to private practice, he would do the work as part of

his hospital services; if the anaesthetist is a part-time officer and entitled to private practice, he may be paid by the patient if the patient arranges for his services privately. Where the patient is in a private pay-bed by private arrangement with the dentist and has been accepted by the dentist under Part IV of the Act: if the anaesthetist is a whole-time officer and not entitled to private practice, he would do the work as part of his hospital services; if the anaesthetist is a part-time officer and entitled to private practice, he may be engaged and paid by the dentist.

NATIONAL SERVICE AND N.H.S. SUPERANNUATION RIGHTS

Under the National Health Service Superannuation Regulations a medical practitioner who joins H.M. Forces may reckon his service in the Forces for superannuation purposes provided he continues to pay the contributions he would have made had he remained in civilian employment. Similarly, the employing authority is required to continue the contributions it would have paid. In general, the amount of the contribution in the case of a practitioner is 6%, and in the case of the employing authority is 8%, of the salary the practitioner was receiving before joining the Forces. If these contributions are not continued the practitioner will be unable to reckon his service in the Forces and will also lose the right to reckon any hospital or other service before joining the Forces in respect of which he paid superannuation contributions. In this case the practitioner is entitled to claim a refund of superannuation contributions already paid plus compound interest at the rate of 2½% per annum.

In the case of practitioners who were assistants to general practitioners in the National Health Service before entering H.M. Forces and who decide to continue their superannuation contributions, the employing authority's contribution of 8% of the assistant's salary is payable not by the general-practitioner employer but by the executive council of the area concerned.

Practitioners entering H.M. Forces who desire to preserve their superannuation rights and to continue their contributions should send prompt notification to the hospital authority or executive council under whose jurisdiction they were last employed, and should make arrangements about the method of paying their own contribution of 6% to these bodies.

LOWER FEES FOR OPTICIANS

Opticians' fees for sight-testing and for dispensing glasses under the National Health Service have been reduced by an agreement of the Optical Whitley Council. The revised fees are being paid from May 1 pending the results of a fact-finding inquiry by a working party, on which opticians will be represented, under the chairmanship of Mr. W. Penman, a past president of the Institute of Actuaries. The working party will investigate the average time taken to provide the services, and there will be a separate investigation into the cost of overheads. The revised rates are as follows:

	New rate	Old rate
Sight-testing by ophthalmic optician	14s.	15s. 6d.
Dispensing glasses	24s.	25s.
Dispensing second pair of glasses of different power for same patients	10s.	25s.
Altering one lens, following a sight-test	12s. 6d.	25s.

In the case of bifocal glasses the fee has been increased from £1 5s. to £1 11s. 6d. Where the optician is not a dispensing optician, or where it is not necessary to prescribe glasses, the fee for sight-testing remains at 15s. 6d.

CLOSED AREA

The Medical Practices Committee has decided that the number of doctors providing general medical services is adequate in the Minchinhampton district of Gloucestershire.

CONTROL OF HOSPITAL EXPENDITURE

The Ministry of Health states that hospital management committees should not in future, without the prior approval of the regional board, incur expenditure on

(a) specific items and increases in staff not included in their estimates, even though the total for the particular sub-head is not likely to be exceeded; or

(b) extension of services likely to involve supplemental estimates. Where the board considers a particular development to be essential, the Ministry should be consulted, full details being supplied with an estimate of the maintenance expenditure likely to be incurred in the particular year and the subsequent annual cost.

This does not apply to expenditure outside the control of the management committee—e.g., wage awards, changes in policy, or sudden emergencies.

RHEUMATISM AND THE N.H.S.

MINISTER'S ASSURANCE

The Liaison Committee of the Empire Rheumatism Council and the British Rheumatic Association has written to the Minister of Health on the development of schemes for the specialist diagnosis and treatment of rheumatism and received his reply. The two letters are published below.

From Lord Horder, chairman of the Empire Rheumatism Council, and Dr. F. Hernaman-Johnson, chairman of the British Rheumatic Association:

"We are writing on behalf of the Empire Rheumatism Council and the British Rheumatic Association at the unanimous request of our Liaison Committee to beg you to safeguard the interests of the rheumatic patient in the present economy drive.

"We recognize the need for economy in the administration of the Health Service Act. We are cognizant that your policy is to meet proportionately the needs of the different types of sick persons. We wish to point out that the rheumatic sufferers are in a particularly unfortunate position and are likely to suffer disproportionately unless a definite assurance is given that such is not your intention.

"In recent years new knowledge has been acquired, but when the health services and hospitals were taken over these had not been made available throughout the country. The absence of facilities for up-to-date diagnosis and treatment increases the economic burden of the country by the steady drain from productive work due to preventable disablement. Regional hospital boards have already, by the guidance and encouragement of the Ministry, started to provide schemes for the specialist diagnosis and treatment of rheumatism. Two have already done so, some others have them in preparation. There is a real danger that on grounds of economy all schemes other than those already approved will be dropped and those boards that have no schemes will continue to do nothing.

"We hope it is your intention that the rheumatic patients should have their fair share of service under the Act, and in the interests of national economy and of human suffering we ask that you will safeguard their position."

Reply from the Minister of Health:

"I appreciate the representations you have put forward in your letter of March 21 on behalf of the Liaison Committee of the Empire Rheumatism Council and the British Rheumatic Association about the provision of diagnostic and treatment facilities for rheumatic patients. As no doubt you will be aware, I have made it known to regional hospital boards that in seeking economies in the administration of the hospital and specialist services they should have particularly in mind the safeguarding of the interests of patients; and I have had no indication that the boards contemplate singling out for curtailment the services for the treatment of rheumatism, or that developments in this field will not continue so far as medical and other resources allow."

INCOME TAX

A proposal has been put to the Board of Inland Revenue that, as the financial position of many doctors has been adversely affected by the National Health Service, practitioners should have the opportunity, if they wish, of paying income tax by quarterly instalments. The Board has replied that it cannot authorize any general arrangement for the collection of tax from doctors by quarterly instalments. It suggests that any doctor who, because of reduced earnings, is unable to meet his tax liability on the due date should explain the position to the Collector of Taxes, who will consider each case on its merits.

PUBLIC HEALTH COMMITTEE

The Public Health Committee met on April 22 under the chairmanship of Dr. J. Fenton.

On the present position with regard to negotiations with the associations of local authorities no progress could be reported, and the policy of the Association with regard to advertisements for appointments in the public health field was being applied. It was reported that no advertisement in accordance with the Association's recommendations had been received, but that twelve had been refused. Ten advertisements had appeared in the lay press and had been made the subject of an "Important Notice" in the *Journal*.

The Chairman of Council reported that representatives of the G.M.S. Committee had recently met officials of the Ministry of Health, and in the course of their discussions a statement was made regarding arbitration (*Supplement*, April 23, p. 237). The profession had regarded arbitration as an integral part of the Whitley machinery. Dr. Dain suggested that the refusal of the associations of local authorities to participate in the approved Whitley machinery might be on account of the associated method of arbitration, in addition to other reasons. The chairman stated: "I think the Public Health Service to a man would never have agreed to Whitley machinery if we had known we were not to have arbitration." The committee agreed unanimously to express to Council its concern and dismay at the Ministry's attitude on this whole matter.

The committee was asked for advice on the position of medical officers shortly due to retire who have been requested by their local authority to remain in office in view of the Association's policy and the non-acceptance of advertisements for public health appointments by the medical press. The committee agreed that no exception be taken to any such arrangement made before Feb. 28, 1949, the remuneration being in accordance with the Modification of the Interim Revision of the Askwith Agreement. Where, however, such a request is made after that date the remuneration must be at the appropriate step on the scales as recommended by the Association. Any other arrangement would be unacceptable.

A "historical review," circulated by the County Councils Association regarding certain discussions on Whitley machinery and the question of negotiating permanent scales of remuneration for medical officers employed by local authorities, was discussed. The chairman called attention to a number of inaccuracies, but as these points had already been dealt with in correspondence by the Association and the Society of Medical Officers of Health the committee decided to take no further action.

Occupational Health Service

Dr. D. Stewart, chairman of the Planning Subcommittee of the Occupational Health Committee, attended by invitation and spoke on the subcommittee's report on the establishment of a co-ordinated occupational health service. The committee expressed general approval of the report, which will be published when it has been approved by the Occupational Health Committee and the Council.

British Medical Guild

The committee next considered the position of medical officers in the Public Health Service in connexion with the British Medical Guild. Dr. Dain referred to the method of contribution by general practitioners through the N.I.D.T., but stressed that other methods would be required for consultants and specialists and public health medical officers. The committee discussed the problem, together with the suggestions before them regarding the local committees. It was agreed to discuss the matter further with the Society of Medical Officers of Health before making final recommendations.

Other business included the reception of several reports of outside bodies and the information that an amendment of the Local Government (Compensation) Regulations, 1948, now enabled a period of war or national service to count in the appropriate period necessary to qualify for compensation on loss of employment or diminution of emoluments.

The Country's Money

Abuse of the Health Service by some patients seems to be worrying the Treasury. It annoys doctors too, for it tends to break up the relationship of trust that all agree should exist between doctor and patient. A doctor tells us that the wife of a diabetic patient on his list asked a few weeks ago for a prescription to replace a broken Record syringe for her husband. She produced the broken syringe and the doctor gave his prescription. A week later she returned with another broken syringe and asked for another prescription. The doctor pointed out that he had supplied one only a week before, but nevertheless gave it. When the same thing happened a week later he declined to give yet another prescription. A few days later he received the following letter from the patient: "Dear Doctor, In future please note if I send over to you for anything which I am entitled to I do not want you to tell my wife that I should buy a syringe, when I want to buy anything I don't want your advice or your complaints as I pay 9s. 8d. per week for your services and everything that goes with it, and I intend to have every ounce of flesh this is the second time you grumbled at my wife and please don't try and save the country money hoping you will keep this in mind."

Trend

A doctor sent us the following letter he has received from a patient "to show," as he says, "the trend of general practice": "Gauze (large roll), powder for my foot, lint, tablets for reducing, have you anything to take a quicker effect than the tablets I am now taking. I have a skin rash of small pimples mostly on the fingers round the nails, they itch very much also on my face, please could I have something for it, also a note for glasses, my old ones are broken, one of the lens have come out, I need them urgently. Thanking you. Please could my daughter have a large bottle of Bland's Pills."

Health Service Tax

We have recently heard suggested another scheme for saving money spent on the Health Service and commend it also to the Chancellor of the Exchequer, whose hints in the Budget speech about a special tax are unlikely to deter any Englishman from altering his accustomed ways until disaster, in this case financial, is upon him. The patient would be taxed 6d. when he visited the doctor, or the doctor visited him, by making him buy a 6d. postage stamp from the doctor. Doctors would buy sheets of them from the post office and stick one on their patients' cards on each occasion. There are some drawbacks: the scheme would make more work for already harassed doctors, and the patients might forget to bring their cards. Again, the Government might think it rather unsocialistic—but many Labour members thought that of Sir Stafford's Budget.

Brass Plates

The brass plate, although there is a certain flourish about it, is not always the most legible means of conveying information. In a doctors' quarter in a provincial town the other day we had occasion to look at a number of brass plates, and on some of them the name could only with difficulty be made out, and the surgery hours were quite indecipherable. Small wooden panels such as have come into vogue in Harley Street, and on which the name can be painted and repainted, although they may have a certain temporary look, can at least be read, as a good many names "writ in brass" cannot.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.
Non-County Borough Councils.—Dartford, WallSEND.
Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Medicines for Private Patients

Q.—In "Medical Notes in Parliament" (Journal, Nov. 20, 1948, p. 921) Mr. Bryan, in reply to a question on the above subject by Sir Wavell Wakefield on Nov. 11, is reported to have stated that "he would not feel justified in supplying [private patients] medicines or appliances ordered by doctor who were not taking part in the Service. . . ." May it be understood from this that doctors who are taking part in the Service may order medicines and appliances on Form E.C.10 for such private patients as may remain to them?

If the answer to the above is in the negative, what is the position with regard to the supply of medicines and appliances by a doctor (who is taking part in the Service) to a patient who wishes to be his private patient and has previously registered on the list of another practitioner?

A.—The reply given by the Minister to Sir Wavell Wakefield on Nov. 11, 1948, is one of many which have been given on the subject of medicines for private patients. In other replies the Minister has made it clear that he is not prepared to admit the right of private patients to receive drugs, medicines, and appliances under the public Service, irrespective of whether or not the practitioner concerned is taking part in the public Service. Under the present regulations a practitioner cannot issue a prescription on E.C.10 to a patient who is consulting him privately, even though that patient may be registered with another practitioner.

Call from Police

Q.—Is it in order for the police to question a doctor on whether he is going to attend a patient on his list? I recently received a telephone call to visit a patient—no statement whether it was urgent or not. I replied that cases requiring visiting should be sent before 10 a.m. An hour later the police rang up to say they understood I had had a call to visit the case and was I going to attend? Thinking it was urgent I went at great inconvenience, to find the man had been in bed for four days with influenza. His chief anxiety was that he wanted a note to say he was unable to attend before the Regional Medical Officer the next day.

A.—No statutory duty is vested with the police to question a doctor on whether he is going to attend a National Health Service patient. In this case it is presumed the patient got on to the police and asked them to find out whether the doctor intended to visit him, and the police, not knowing whether the case was urgent or not, thought it right to get in touch with the doctor. The onus of deciding when a patient is visited must rest with the doctor, and the patient has his remedy if he considers his request to the doctor has not been reasonably dealt with.

Earnings and Superannuation

Q.—I am employed by a regional board as a part-time consultant. My work includes hospital sessions and domiciliary consultations as a surgeon. Does the amount I earn from domiciliary consultations count for pension in the same way as the salary for hospital sessions?

A.—Yes. Superannuation deductions and benefits are related to remuneration, and the Superannuation Regulations define the term "remuneration" to include all salary, wages, fees, and other payments paid or made to an officer as such for his own use, and also the money value of any apartments, rations, or other allowances in kind appertaining to his employment. It does not include payments for overtime or any allowances paid to him to cover the cost of providing office or laboratory accommodation or clerical or other assistance, or any travelling or subsistence allowance or other moneys to be spent, or to cover expenses incurred by him, for the purposes of his employment.

Correction.—Under the heading "Salary for Trainee Assistant" in the Supplement of April 23 (p. 239) the figure £750 should have been £700 as the maximum sum payable to a trainee assistant to provide for salary and boarding expenses. The figures tabulated in the example are correct.

Correspondence

Loading by Age

SIR,—In the *Journal* of April 16 (p. 685), under "Medical Services in Parliament," Mr. Bevan is reported as saying that here were doctors with lists of 4,000 who had fewer patients attend than had some doctors with a list of only 3,000. In parts of the country where the average age of the population is high, a higher percentage of people would need to see a doctor."

This is clearly a statement of fact, but it is not easy to assess the amount of extra work involved by having older patients, and this would only be possible by means of a complicated analysis of work done for patients at all age levels. The issue which arises is whether doctors should be paid more *caput* if their practices contain high proportions of old people, and this could be done in two ways: (a) by increasing the number on the list by multiplying by the average age, or giving the district concerned a larger local pool in proportion to the average age of the local population; (b) by giving extra capitation fee for patients over a certain age, say years. Both of these methods involve complications and extra administrative work and therefore must be justified as necessary.

Offsetting them is the theory that the older age groups congregate only in the more desirable areas, and that the doctors to practise in these areas should not expect to be as well paid as their colleagues who practise in other less desirable places. How can this factor be evaluated? I suppose that the answer is to allow doctors to distribute themselves as freely as possible. This has been B.M.A. policy, but I am surprised that the matter of loaded capitation fees for older patients has been little discussed.—I am, etc.,

W. J. BURDON.

J. F. BURDON.

Medical Service Committees

SIR,—We read under the heading "Medico-Legal" (*Journal*, April 9, p. 638) that a medical service committee has investigated a complaint of negligence. We read that "the committee found as follows. . . ." Finally we learn that representations were to be made to the Minister to withhold £10 from a certain practitioner's remuneration. In plain English, he is to be fined the sum of £10.

Certain thoughts arise from this affair, which is not the first of its kind. It is odd to find a committee, or for that matter the Minister of the Crown, assuming the robes of justice. I had always thought that in this country the executive and the judiciary were widely apart in their functions.

We may expect cases of this kind to multiply in the future, perhaps with consequences that will be diverting and instructive. Suppose that a complainant also institutes proceedings under common law. What will the position be if the court finds negligence proved after a "committee" has recommended, and the Minister has imposed, a fine for negligence?

Some of your readers with legal qualifications may have something to tell us if they think it worth while, and will perhaps correct me where I am wrong.—I am, etc.,

W. J. BOLD.

W. J. BOLD.

Whitley Machinery

SIR,—At the Special Representative Meeting on Wednesday, March 30, when opposing the formation of a Medical Guild, I pointed out that the policy of the British Medical Association is in favour of Whitley Council machinery involving negotiations between employers and employees, and, in the event of dispute, recourse to independent arbitration.

In his reply the Chairman of Council stated (*Supplement*, April 9, p. 223): "If it were true that the Whitley Council covered all possibility of disagreement with the Government there would be no need for this new body. But the Whitley Council would cover only certain aspects of their contract and there would be a field outside Whitley Council procedure which must be covered by themselves."

This reply is quite beyond my comprehension, as I have always been led to believe that the function of the Whitley

Council would be all-embracing. Adherence to the Whitley Council machinery being the accepted policy of the Association, I feel it is essential that the position be clarified at once. What are the items of service or salary conditions with which that Council will not be competent to deal? It is known, of course, that the proper interpretation of the Spens Committee findings is being argued at present; but, once Whitley machinery were in existence, what matters, as I say, would not come under their purview?

Our greatest asset as a democratic organization is our moral strength, and recourse to independent arbitration would inevitably ensure our just demands being met. If the proposed machinery cannot meantime deal fully with the position, then surely our efforts should rather be directed towards any alteration necessary to ensure that this defect is remedied.—I am, etc.,

JOHN RIDDELL.

JOHN RIDDELL.

The Secretary of the Association writes: It is not expected that there will come within the ambit of Whitley machinery every question which arises between the Ministry of Health and the profession. For example, the terms of service of the general practitioner go into considerable detail about certification, prescribing, forms of records, and allocation of patient. It is probable that discussions on such matters as these will take place directly between the Ministry and the profession's representatives. On the other hand it has been clearly understood that major issues of remuneration do fall within the ambit of Whitley machinery. It was with this in mind that the Chairman of Council made his statement. The whole picture is now changed by the Ministry's change of attitude on the subject of arbitration in association with Whitley machinery, a point which has been fully dealt with in recent issues of the *Journal*.

Breach of Faith

SIR,—I wish to congratulate you on your leading article in the *Journal* of April 30 (p. 762). Some of us, who have never ceased from warning the profession, never expected any other result from the Ministry. However, I do not agree with your contention of the value of the British Medical Guild, and I have no intention of supporting it as it stands. Many changes are needed badly, and I do not support men who do not know their own minds from one Saturday to the following Wednesday, nor understand the meaning of the word freedom. Surely the time is fast approaching when the dictatorial methods of the Minister must cease, or the profession will put an end to his Health Service.—I am, etc.,

H. V. DEAKIN.

H. V. DEAKIN.

Position of Registrars

SIR,—I heartily endorse all that Mr. I. Langdale Gregory states with regard to the position of registrars (*Supplement*, April 9, p. 227), and entirely agree that the B.M.A. should do something for the registrar class. So much notice is being taken of the complaints of the G.P.s and consultants. It is disappointing to read that negotiations concerning the appointments and remuneration under the N.H.S. Act for registrars are few and far between.

I beg to disagree with Mr. Langdale Gregory that war service in the armed Services should count towards seniority in any new appointment. I am sure there were many men who were graded out of the Services on medical grounds. Many of them immediately joined the E.M.S. and served their country in that way. I feel that it would therefore be unfair if a new appointment was denied to a man who had not been admitted to the Services simply on medical grounds. No "grant" was given to those who served in the E.M.S., which would have helped towards paying the expenses of gaining a higher degree.

It has been stated that registrars are to be divided into three grades. We do not know, however, whether a registrar is to be graded according to the number of years he has held registrar posts or according to the post he holds at the time of grading. The former is much the fairer method, and I feel that the B.M.A. should urge that point. If a registrar is to be graded according to the post he holds, then that man may never have held a registrar post before and yet find he is

graded I; on the other hand, a registrar who had held similar posts for some years may find that he is only in a Grade II post. That method of grading would, I think, be most unfair.

Permit me to add two further points: (a) no allowance has been given for superannuation contributions and deductions for N.H.I., which is a considerable added expense; (b) some registrars will have changed their posts since July 5, 1948. I trust that retrospective remuneration will still be from that date and not from the date of acquiring the new appointment.—I am, etc.,

Rules for Patients

SIR.—At last, after nine months of the N.H.S., the B.M.A. has realized that it would be a good thing to have a few rules and obligations for patients. Why this important point was not discussed before the appointed day will remain as much of a mystery as the omission of discussion of the mundane details of remuneration and compensation.

Fatigued though I am, and nine months nearer to my coronary thrombosis, I can just summon sufficient energy to request the B.M.A. to create some form of machinery whereby (a) the doctor would be protected from flippant night calls (e.g., when the baby won't go to sleep); (b) the patients would be prevented from whistling and shouting from doorways and windows in order to obtain visits; (c) the patients would be prevented from waylaying the doctor on his rounds in order to save a visit to the surgery; (d) the patients would be prevented from leaving messages for multiple visits in houses where the doctor is known to be attending. While such a state of anarchy exists no doctor can plan his day—or night.—I am, etc.,

Senior Hospital Officers

SIR.—To vigilant observers it must by now have become sufficiently clear that a rigorous process is going on, apparently for reasons of economy, whereby contracts conferring "full staff specialist and consultant status" will numerically be reduced to a minimum. This process will have most serious consequences for hundreds of senior officers in hospitals who on account of long years of service in a specialty (in some cases amounting to more than a decade), and also of scientific contributions, were until recently confident that they would have to be regarded as specialists.

Under these circumstances it would be only fair if, in order to avoid a widespread sense of frustration, the appropriate representatives would urge for an amendment whereby senior hospital officers would become eligible for one or two of the lower grades of the distinction awards, which for this purpose could be arranged in four grades. Quite a number of colleagues concerned with whom the writer has contact hold these views on the matter, and it is in the interest of such and like that the above suggestion is put forward for consideration.—I am, etc.,

Sickness Benefit

SIR.—May I be permitted to draw attention to an obviously unpremeditated injustice inherent in the National Insurance Act? Many tuberculous patients are incapacitated from earning their livings for much longer than 12 months. A patient who fell sick with this disease just before Jan. 5, 1948, and had only made 25 contributions to the N.H.I., receives no sickness benefit whatever. Another patient who became incapacitated just after and had 26 contributions to his credit is receiving and will continue to receive benefit, but at a reduced rate, for one year (312 days) before he can afford a relapse he must make 13 contributions, when he will be entitled to benefit for a further period of 312 days.

Looking ahead, there will be patients falling sick with pulmonary tuberculosis in June, 1951, who will only have paid 152 to 155 contributions. It appears that if they allow themselves to be incapacitated at once they will receive full benefit for 312 days only, whereas if they postpone it until they have

paid 156 contributions they will be entitled to sickness benefit "without limit of time up to pensionable age."

Is there any legal onus on the Class II (self-employed) patient to "go sick" as soon as he is diagnosed, or upon his doctor to "put him on the club"? Or can the patient say, "All right, I will go to bed, to hospital, to sanatoria, and will follow all the advice you suggest, but I shall continue to employ myself thinking beautiful thoughts and planning a better future for myself. I have 156 stamps on my card, and then I will chuck it and you shall put me on the club"?

Could a Class I (employed) patient who falls sick in similar circumstances say, "All right, I am for the time being no longer of any use to my employer but I am still a lot of use to myself, so I will transfer to Class II and will employ myself thinking beautiful thoughts, etc."?

If the above suggestions are in order, prospective tuberculous patients and their doctors should be advised in order that they may not suffer unnecessary hardship. If not, they should be warned not to try it on.—I am, etc.,

Murderley, Norfolk.

Night Service for Doctors

SIR.—Having practised medicine continuously for fifty years and intermittently for the last ten years, I advise young doctors to try to combine and secure a night service of doctors for patients, and to take the strain off their nervous system. At the age of 82 all my confreres seem to be dead—as far as I know. In towns of a small population one doctor could do night duty for one week and so have a rotation, but in a large town the best plan would be special doctors to be appointed for night work.

I have advocated all midwifery to be handed over to specialists in the interest of the patient as well as of the doctor. Thus a medical man would not be continuously on the chain and would get some relief from the daily exhausting grind of day and night work; and I believe the expectation of life would rise at least ten years.—I am, etc.,

Special Tax

SIR.—Sir Stafford Cripps in his Budget speech mentioned the possibility of having to introduce a special tax or charge to help pay for the cost of the National Health Service. Mr. George Schwartz has elaborated this theme in an extremely enlightening article in the *Sunday Times* of April 24. I suggest that a charge of 10% of the cost of treatment should be made to the patient, and argues that this would cut down the demands on the Health Service besides helping to pay for it.

Collection of fees by hospitals, institutions, and chemists would be simple, but payment for general-practitioner services would be more difficult unless a flat rate of, say, 1s. per item of service was introduced—payable at the time to the doctor.

There is no doubt that the Service is being somewhat abused by the public and that the cost to the country is likely to increase in the future. Under these circumstances the prospect of an increase in remuneration for the medical profession will become more and more remote.

I suggest that the British Medical Association should very seriously consider this principle of contributory payments by the patient for use of the Health Service, and urge its introduction in due course.—I am, etc.,

F. G. WOOD-SMITH

Assistantships

SIR.—May I again express some of my views regarding assistantships and partnerships? I agree heartily with "Another Assistant" and "X. Y. Z." (*Supplement*, April 23, p. 250). With regard to hospital experience I consider this to be an invaluable apprenticeship to any branch of medicine and surgery and especially to G.P. work. The last sentence in "X. Y. Z.'s" contribution is in my opinion absolutely correct.

My own experience as an assistant is that, if adequate provision is not made for G.P.s, "partners," and "assistants," I too, already well advanced in the process of "unlearning" (very aptly put by "X. Y. Z.") because I have no time or leisure

which to study, keep up to date, or even re-learn, shall soon be "reduced to the ranks" of those whose panacea for most ills appears to be a certificate and a bottle of medicine. Is this that the N.H.S. wants? Incidentally I am not encouraged to attend confinements or do vaccinations or immunizations, and I am rash enough to undertake the latter I am asked to return the cards to my "boss" for signature. The answer to this is surely obvious.
